WITHINGTON, C. F., M.D.  
WOOD, E. S., M.D.  
WOOD, H. C., M.D.  
WOODBURY, F., M.D.  
WOODWARD, L. E., M.D.

- Brooks, W. K.** Influences determining sex, 48.
- Brower, D. R.** Locomotor ataxia: its diagnosis and treatment in the prestatic stage, 375.
- Brown, B.** Double congenital displacement of the hip, description of a case with treatment results in cure, 341.
- Brown, W. S.** Forty years' experience in midwifery, 241, 250.
- Bruen, E. T.** Three cases of tuberculosis, 131; case of abscess in the supra-nasal capsules, 479.
- Bryant, J. D.** Three cases of ligation of the external carotid, in cases of which both vessels were tied simultaneously, 355.
- Burrell, H. L.** A consideration of the management of patients during etherization, 97, 107; cases of perineal abscess dependent on urethral stricture, 263; report of progress in orthopedic surgery, 391.
- Byford, H. T.** Functions of the membranes in labor, 327.
- Byford, W. H.** A case of mural pregnancy, 37; two cases of mural pregnancy, 325.
- Cabot, A. T.** Report on surgery, 7; the constrictor muscle—its relations to urethral pathology and treatment, 339, 348.
- Cacofolia.** Addison's disease, 258.
- Cæsarean Section.** Antio-Cæsarean section. Von Guggenberg, 331.
- Calculus.** Cases of urino-cæcal, Gerrish, F. H., 6.
- Cannmann, D. M.** The history of the stethoscope, with the presentation of a modification of Canham's method, 573.
- Cancer.** A case of cancer of the head of the pancreas, Rotch, T. M., 175, 177; increase of cancer in Great Britain, Dana, H. P., 262; malignant disease of the thyroid gland, Webster, C. E., 250.
- Capron.** Case of diplopia, 319.
- Carbolic-acid Potentiation.** Draper, F. W., 9.
- Carlshad in former times,** 166.
- Carney Hospital,** 331.
- Carver, A.** More telepathy, 329.
- Cassell, E. T.** Repeated lithotomy, 15.
- Cataract.** The etiology and treatment of nasal cataract, with special reference to deviated septum, Jarvis, W. C., 279; catarhthal affections of the nasal cavities as a cause of pulmonary phthisis, Jarvis, W. C., 553.
- Cervix Uteri.** Observations on the cervix uteri, Hosmer, A., 204; Emmet's operation for lacerated cervix, under hydrochloric acid, Koeth, A. G., 527.
- Chadwick, J. R.** Gradual reposition of an inverted uterus by a new contrivance, 289, 291; rupture of the vagina during coitus, 163.
- Chamberlain, M. L.** Vaginal douches, abdominal and vaginal coils, rubber tubing containing brass wire spiral, 245.
- Channing, W.** Report on case of the insane, 322.
- Chapman, D. W.** Obituary notice of H. C. Thomas, M.D., 69.
- Chemistry.** Report on medical chemistry, Hills, W. R., 291; a new and simple apparatus for determining the quantity of urea in the urine, Doremus, C. A., 324; a peculiar form of uric-acid precipitate, Edles, F. W., 389.
- Chorea.** Hysteria Chorea, 311.
- Children.** Incontinence of urine in children, Smith, J. L., 449; report on diseases of children, Rotch, T. M., 172.
- Chloroform.** A new mode of using an old remedy—chloroform-water, 92.
- Cholera.** Janeway, E. H., 11; demonstration of Koch's cholera bacilli, Wendi, C. E., 138; preparation against cholera, Fitz, R. H., 184, 177, 196; discussion of the best sanitary and therapeutic measures for the prevention and control of epidemic cholera, Purging, S. H., 221; cholera and its treatment by Dr. John Chapman's method, with twelve cases, Kincaid, B. O., 276; cholera—anal and rectal partem, 286; cholera warnings, 331; cultivation of the cholera bacillus and of other allied microorganisms, Billings, E. C., 476; cholera and cholera prevention in Spain, 539; the non-contagiousness of cholera Asiatica, Smith, J. L., 392.
- Chorea.** Chorea as a hysteria nervosa, Lyman, G. H., 274; some clinical observations in regard to mono-chorea associated with increased temperature of the part affected, Hare, H. A., 317; the local pathology of chorea, Wood, E. S., 123.
- Chloridia Ravennas.** Its influence upon parturition, Knox, J. S., 151.
- Circulatory System.** Case of ulcerative endocarditis, Shattuck, G. B., 32; report of a case of occlusion of the vena cava superior, and of a case of embolism of the arch of the aorta, presenting stenosis without symptoms, Gannett, W. W., 137; the rupture of veins, 260; recent progress in thoracic disease, Shattuck, F. C., 220; two cases of nevus pigmentosus, Schweinitz, G. E. de, 227; electricity as a stimulus in cardiac and respiratory failure, Griswold, G., 231; case of aneurism of the arch of the aorta, presenting unusual difficulties in diagnosis, Flint, A., 255; death from hamorrhage into the pancreas, Reynolds, J. P., 274; a case of cardiac (??) aneurism, Noff, J. S.; larynx, trachea, lungs, and heart from a case of angiose diptheria, Edwards, W. B., 302; a enormous false aneurism of the left trunk communicating with a true aneurism of the abdominal aorta, Shattuck, G. B., 337, 347; on the healing of arteries after ligation, Warren, J. C., 317; cure of aneurism of the abdominal aorta by ligature and introduction of silver wire, 351; an experimental and clinical study of air embolism, Scott, S., 234; specimen of aneurism of the aorta, with rupture into the trachea in two places, and perforation of the esophagus, Osler, W., 140; some non valvular diseases of the heart, Edles, R. T., 96, 501; three cases of ligation of the external carotid, in cases of which both vessels were tied simultaneously, Bryant, J. D., 355; specimens of ulcerative endocarditis and of abscess of the liver, Janeway, E. G., 591.
- Clavicle.** Sarcoma of the clavicle, Schweinitz, G. E. de, 206.
- Climate.** The selection of a suitable climate for the various forms of pulmonary consumption, Fowler, J. H., 517, 546; a rule for the even division of climate, based upon the average of the combined atmospheric humidities in the United States, Denison, C., 577; geographical distribution of phthisis in Michigan, with sketch of topography, Shurley, J. L., 577; the problem of a climatization, Flint, A. H., 577; remarks on the climate of Florida, Wilson, J. C., 57; the climate of central Florida, Keating, 578; the results of the home treatment of consumption, contrasted with those of changed residence and climate, Hudson, E. D., Jr., 578.
- Clinical Cases.** The effect of our sudden and repeated changes upon children, 31.
- Cocaine.** Cocaine and curcette, Tilden, G. H., 56; cocaine, Williams, H. W., 86; cocaine discs, Warren, J. W., 165; cocaine in urethrotomy, Garland, G. M., 127; use of cocaine in otitis, Hooper, F. H., 128; cocaine in the dilatation of urethral strictures, Dixon, R. B., 205; cocaine, cocaine, Squibb, E. R., 253; cocaine for sleeplessness, Woodman, W., 287; Emmet's operation for lacerated cervix, under hydrochloric acid, Koeth, A. G., 527; cocaine with pilular, Bradford, H. W., 337.
- Collective Investigation of Disease by the Medical Society of the Commonwealth of Massachusetts,** 323.
- Color-blindness.** Railway accidents and color-blindness, Thomson, W., 214.
- Comer, P. S.** The etiology of tetanus, 435.
- Constipation.** The treatment of constipation, 306.
- Contagious Diseases.** Hospital accommodation for contagious diseases, 188.
- Cordeiro, F. J. B.** Death from overdose of opium, 512.
- Cosmese Sublimine Injections.** Richardson, W. L., 413.
- Croup and Diptheria.** 578. The treatment of croup and intubation of the larynx, Waxham, F. E., 478.
- Curace—Juncide,** 330.
- Curt Battery,** 581.
- Cushing, H. W.** Letter from Berlin, 489.
- Cutaneous System.** Cocaine and curcette, Tilden, G. H., 56; scabies in army, Wilder, A. M., 68; raised circular patches on the palmar surface of over two years' duration, Greenough, F. B., 86; lepra, Williams, H. W., 86; army itch, White, J. C., 94; sarcoma of skin, etc., Ludlow, 131; two cases of nevus pigmentosus, Schweinitz, G. E. de, 227; report on dermatology, Tilden, G. H., 113; the effect of cocaine in the treatment of a case of traumatic linear atrophy, Bowditch, V. Y., 617, 624; multiple sarcoma of the skin: treatment by hypodermic injections of Fowler's solution: recovery, Shattuck, F. C., 618, 624; increased frequency of scabies, Greenough, F. B., 619.
- Cutis Ery.** Cases of chronic catarrhal pneumonia (phthisis pulmonum) with arrest of the disease and subsequent recovery from the symptoms, 255.
- Darling.** Dr. Darling's Poem, Wm. Osler, 69.
- Daxopast.** E. F. Quality of some of the pharmacopoeial drugs in common use, 500.
- Davenport, F. H.** Report on progress in gynecology, 125.
- Davis, T. G.** Tetra solium in a child two years of age, 281.
- Davis, G. W.** Letter from Vienna, 189.
- Delirium Tremens.** Pathogeny and treatment of delirium tremens, 19.
- Denison, C.** A rule for the even division of climate, based upon the average of combined atmospheric humidities in the United States, 577.
- Dentistry.** Report on dentistry, Rollins, W. H., 620.
- Derby, H.** Unintentional artificial ripening in a case of zonular cataract, 268, 349.
- Dermoid Tumor.** A case of dermoid or piliferous tumor, with cure by spontaneous opening in the intestine, Allee, W. F., 445.
- Dialysis.** Case of chronic diffuse nephritis and amyloid degeneration of the kidneys, complicated, toward the close of life, with glycosuria and inosuria, Wood, E. S., 123, 128; diabetes mellitus, Satterthwaite, 370.
- Digestive System.** A case of carbolic-acid poisoning, Draper, F. W., 9; Mounier's iron in diarrhea, Williams, E. T., 127; a case of cancer of the head of the pancreas, Rotch, T. M., 175, 177; enteritis and gastritis successfully treated with ergot, Bradford, E. R., 220; foreign body in the esophagus successfully treated by aponeurotic incision, 105; case of chronic diffuse nephritis and amyloid degeneration of the kidneys, complicated, toward the close of life, with glycosuria and inosuria, Wood, E. S., 123, 128; rheumatic glossitis, 262; death from hemorrhage into the pancreas, Reynolds, J. P., 274; hygrotona lingue, Zeisler, J., 281; gastrostomy with dilatation of the orifices of the stomach, 282; sarcoma of retro-peritoneal glands, Tyson, J., 300; the treatment of constipation, 306; diabetes mellitus, Satterthwaite, 370; the surgery of the gall-bladder, 127; a case of cholecystostomy, Parkes, C. T., 437; phosphorus necrosis of the pharynx, Mears, J. E., 437; a case of pharyngeal cancer, eucettitis, Doe, G. W., 469, 477; intestinal stricture, Shakespeare, E. O., 408; specimens of ulcerative endocarditis and of abscess of the liver, Janeway, E. G., 581; demonstration of the position and length of the sigmoid flexure of the colon; and Hunter's valves of the rectum, Otis, W. J., 606; report on the clinical history of the rectum, Otis, W. J., 620.
- Diptheria.** Discussion on diptheria, 61; the medical treatment of diptheria, Keating, J. M., 73; larynx, trachea, lungs, and heart from a case of angiose diptheria, Edwards, W. B., 302; croup and diptheria, 578; diptheria and its treatment by carbolic acid, Murray, S. L., 555.
- Diplomas.** More diplomas, 366.
- Directory.** A proposed medical directory of the United States, 162.
- Dispensary.** A paid service in the New York Dispensary, 114.
- Dixon, R. B.** Cocaine in the dilatation of urethral strictures, 202.
- Doe, G. W.** Polygalactia, 414; the treatment of threatened mastitis, 415; a case of pseudo-membranous enteritis, 469, 477.
- Doremus, C. A.** Some remarks on the value of permanganate of potash in menorrhagia, 153.
- Doremus, C. A.** A new and simple apparatus for determining the quantity of urea in the urine, 324.
- Douches.** A guide for adjusting to the routine use of the vaginal douches in normal children, Adams, Z. B., 172; the routine use of the vaginal douche after normal childbirth, 187; vaginal douches, abdominal and vaginal coils, rubber tubing containing brass wire spiral, Chamberlain, M. L., 245.
- Draper, F. W.** A case of carbolic-acid poisoning, 9; recent progress in forensic medicine, 51, 206.
- Draper, W. H.** Antiphrasy and its effects, 335.

- [illegible]

- fibrinos and general (tubercular) peritonitis. Fisher, H. M., 88; diseases of the Fallopian tubes: their relations to uterine displacements and the use of pessaries. Wylie, W. G., 109; report on progress in gynecology. Davenport, F. H., 125; the use and abuse of Hoyer's and Tait's operations. Baker, W. H., 150; anilocular ovarian cyst. Homans, J., 158; muscular cases of vesico-vaginal and vesico-uterine fistula. Baker, W. H., 163, 264; observations on the cervix. Merz, Hosmer, A., 264; three cases of hæmatocele, one death. Morris, M. A., 243; gradual reposition of an inverted uterus by a new contrivance. Chadwick, J. R., 29, 294; ten cases of removal of uterine tumors by laparotomy. Homans, J., 233, 318; rupture of the vagina during colitis. Chadwick, J. R., 433; uterine carcinoma of unusually rapid development. Abbott, S. L., 416; endometritis. Homans, J., pathology, diagnosis, and treatment. 445; some points in the surgery of hyperthrophied prostate. Gould, J. W. S., 454; a case of dermoid or piliferous tumor, with cure by spontaneous opening into the intestine. Albee, W. F., 445; some remarks on the value of permanganate of potash in amebiasis. Hooring, E. J., 452; two cases of dangerous hemorrhage from rupture of the vagina during first colitis. Muir, P. E., 451; fibroid tumor of the ovary. Homans, J., 476; double vagina. Green, C. M., 177; chronic prostritis. Tilden, G. N. and Watson, F. S., 403; Emmet's operation for lacerated cervix, under hydrochlorate of cocaine. Girth, A. G., 527; hypertrophy of the prostate gland. Forteney, J. C., 557; the influence of sea-voyaging upon the genito-uterine functions. 584; dermoid cyst of the ovary. Ebbot, J. W., 607.
- Germ Theory of Disease.** 114; the germ theory of disease in its relation to therapeutics, 274.
- Gerrish, E. H.** Cases of urinary calculus, 6.
- Goodell, F. B.** A case of bipharyngeal poisoning, 252.
- Gordon, J.** General Gordon from a medical point of view, 196.
- Gordley, J. W. S.** Notes on contracture of the bladder consequent on erythrits, 253; some points in the surgery of hypertrophied prostate, 434.
- Gradle, H.** Nervous symptoms due to overlooked anomalies of the eye and ear, 477.
- Grant, C. M.** The case of General Grant, 284.
- Greenough, C. M.** Report on obstetrics, 101; double vagina, 477.
- Greenough, F. B.** Raised circular patches on the palmæ surface, of over two years' duration, 86; cases of cerebral symptoms in early (secondary) syphilis, 571, 595, 607; increased frequency of scabies, 619.
- Grayfold, G.** Electricity as a stimulus in cardiac and respiratory failure, 241.
- Gross, S. W.** Nephrectomy: its indications and contra-indications, 423.
- Gutzengberg, von.** Auto-Cæsarean section, 323.
- Guth, H. M.** Compound dislocation of the femur, 375.
- Guy, D.** Researches on the physiological, chemical, and therapeutic properties of humanis virginea, 501.
- Gynecology.** Report on progress in gynecology. Davenport, F. H., 125.
- Hain, J. R.** Treatment of fractures of the femur without splints, 190.
- Hæmatocele Virginia.** Guy, H., 361.
- Hare, H. A.** Some clinical observations in regard to mono chæmia associated with increased temperature of the part affected, 317.
- Harvard University.** Annual report of the president and treasurer, 1883-4. The medical school, 257.
- Harvey's** manuscript letters. Sieveking, E. H., 213.
- Haven, H. C.** Poor fool at the Massachusetts Medical Society dinner, 529.
- Hay, M.** On the use of concentrated solutions of saline cathartics in dropsy, 585.
- Hay Fever** and allied affections. Bosworth, F. H., 578.
- Helfinger, A. C.** Circular ptythion wards, 112.
- Hewitt, G.** The "menstrual" vomiting of pregnancy, 196.
- Hills, W. B.** Report on medical chemistry, 291.
- Hinsdale, G.** Compound fracture of the leg and foot: amputation after one year's recovery, 151.
- Hollopeter, W. C.** Inverse type of temperature in typhoid fever with a prole of two cases, 28, 33.
- Holmes, O. W.** Letter from Dr. O. W. Holmes to Dr. Forbyle Barker, 165.
- Homans, J.** Exploratory abdominal incisions, 19, 25; anilocular ovaritis, 158; spinal ovaritis, 215; ten cases of removal of uterine tumors by laparotomy, 233, 318; fibroid tumor of the ovary, weighing twenty-two pounds. Lipon of the thigh, weighing twelve pounds. Sarcoma of the leg, 176.
- Hood, J.** Treatment of consumption. Shattuck, F. C., 576; the results of the home treatment of consumption contrasted with those of changed residence and climate. Hudson, P. D., Jr., 578.
- Hooper, F. H.** Use of cocaine in case of colitis, 128.
- Hopkins, G. G.** Report of a case of recurrent fibroma of the bladder at seven and eleven years of age, 290.
- Horse and Buggy.** Are the doctor's horse and buggy his tool? 587.
- Hosmer, A.** Observations on the cervix uteri, 261; apparatus for washing out the bladder, 295.
- Hospital** as combination for contagious diseases, 188.
- Hospital Construction.** Circular ptythion wards. Helfinger, A. C., 112.
- Hudson, C. D., Jr.** The physical examinations of weak chests and differential diagnosis of the several forms of early phthisis, 563; the results of home treatment of consumption contrasted with those of changed residence and climate, 578.
- Hudson, M. Dr.** Hudson a warning. Richard on, W. L., 190.
- Humidity.** A rule for the even division of climate, based upon the averaged combined atmo-spheric humidities in the United States. Denison, C., 572.
- Hunter, J. R.** Endometritis fungosa: its pathology, diagnosis, and treatment, 416.
- Hutchinson, J. C.** Address before New York State Medical Association, 18th April, 1884, 257.
- Hygiene, Health, and Board of Health.** Hygiene of the premises and habitation of three hundred cases of typhoid fever. Swartz, G. T., 16; the Massachusetts health report, 136; preparation against cholera, 13; another health bill before Congress, 629; public health in West Virginia, 190; sanitary council of the Mississippi Valley, 215; discussion of the best sanitary and therapeutic measures for the prevention and control of epidemic cholera. Duran, S. H., 224; the dangers of water-gas, 253; noise as a factor of disease, 285; report on public hygiene. Abbott, S. W., 293; the sanitary condition of Nantucket. Williams, H., 396, 429; the principles of sanitary plumbing. Putnam, J. P., 385, 409, 439, 448; the sanitary condition of Nantucket. Abbott, S. W., 355; the contagiousness of scarlet fever, 402; annual report of the New York State Board of Health, 405; overpressure at school as it affects girls, 462; the artificial ponds in the New York Central Park, 457; an epidemic of typhoid fever from contaminated sewage, 569; Massachusetts health again a victim to lunacy and charity, 585; Dr. H. P. Walcott and the Massachusetts Board of Health. Charles, C., 611; an instructorship of hygiene in the Boston public schools, 614.
- Hygroma Lingue.** Zelsler, J., 281.
- Hypnotism.** Hypnotic Chicago, 524.
- Hyrtl.** Professor Hyrtl's jubilee, 446.
- Hyd.** A new illud, 308.
- Illinois.** The official register of physicians in Illinois, 65.
- Imprisonment** of members of the Massachusetts Medical Society, 678.
- Infective Medians.** 118, 395.
- Ingalis, E. F.** Emphysema, paracentesis, and drainage, 376.
- Insane Criminals.** 113.
- Insane Hospitals.** Fires in insane hospitals, 186; business management of insane hospital, 210.
- Instrumental Apparatus.** New obstetric forceps and vaginal speculum. Schuyler, W. D., 108; apparatus for washing out the bladder. Hosmer, A., 265; vaginal douches, abdominal and vaginal coils, rubber tubing containing brass wire spiral, Chamberlain, M. L., 245; urethral sounds. Post, A., 255; the electric light for surgical illumination. Baker, W. H., H., 291; a new and simple apparatus for testing the quantity of urea in the urine. Dornicus, C. A., 324; the posterior splint for the forearm. Dulles, C. W., 533; a useful form of ligature. Lathrop, W. H., 562; a contribution to the mechanical treatment of diseases of the knee-joint. Stillman, F., 568; further consideration of pneumatic diffraction, with demonstration of the pneumatic cabinet. Williams, H. F., 556; the history of the Cammann stethoscope with the presentation of a modification of the Cammann stethoscope. Cammann, D. M., 579; Curt battery, 581.
- Iodoform.** A case of iodoform poisoning. Goodell, G. Z., 352.
- Itch.** Scabies in the army. Wilder, A. M., 85; army itch. White, J. C., 94.
- Jacksonian Epilepsy.** Osler, W., 587.
- Jacobi, A.** Inaugural address, 184.
- Jacobi, M. P.** Diphtheria, 61.
- Janeway, E. G.** Cholera, 11; intestinal lesions of typhoid fever, 13; rare pathological specimens, 324; the advance in our knowledge of the etiology of disease, 579; specimens of ulcerative colitis and of abscess of the liver, 581.
- Jarvis, W. C.** The etiology and treatment of nasal catarrh, with special reference to deviated septum, 279; catarrhal affections of the nasal cavities as a cause of pulmonary phthisis, 553.
- Jeffries, Dr.** Jeffries' aerial voyage across the English channel 193.
- Judson, A. S.** The management of the abscesses of hip disease, 531.
- Jurispudence.** Recent progress in forensic medicine. Draper, F. W., 154, 206.
- Keating, J. M.** The medical treatment of diphtheria, 73; the clinical course of diphtheria, 57.
- Kinney, E. O.** Cholera and its treatment by Dr. John Chapman's method, with twelve cases, 276.
- Klein, C. H. von.** Roller-skating, 334.
- Knapf, P. C.** Cutaneous and deep reflexes, 34.
- Kneel, C.** Contribution to the mechanical treatment of diseases of the knee-joint. Stillman, F. C., 558.
- Knox, J. S.** The influence of *Cladifraga racemosa* upon parturition, 451.
- Koel's Cholera Bacilli.** Weert, C. E., 108.
- Lachrymal Gland.** Slides from an adenoid-fibroma of lachrymal gland. Schweitzer, G. E., de, 227.
- Laparotomy.** Ten cases of removal of uterine tumors by laparotomy. Homans, J., 233, 318.
- Lathrop, W. H.** A useful form of ligature, 562.
- Lawrence, R. M.** Old medical announcements, 262.
- Lecture System.** Thomas, F. S., 334.
- Lepora.** Williams, H. W., 86.
- Liberia.** Letter from Liberia. Roberts, J. H., 165.
- Ligature.** A useful form of ligature. Lathrop, W. H., 562.
- Lislerism.** The results of Lislerism in amputation of the breast. Galloppe, C. W., 552.
- Litholapaxy.** Caswell, E. T., 15.
- Little's Disease.** Cases of congenital muscular rigidity, or Little's disease. Bradford, E. H., 217.
- Locomotor Ataxia.** Its diagnosis and treatment in the preatonic stage. Brower, D. R., 375.
- Lomb Prizes.** 165.
- London.** Letter from London, 11; letter from our London correspondent, 164.
- Longstreth, M.** Alveolar sarcoma of the kidney, 206.
- Loomis, A. L.** Address before American Climatological Association, 1884, 251.
- Lovell, R. W.** Letter from the Adirondacks, 117.
- Lowell, S. J.** St. John's Hospital, Lowell, 514.
- Lupus.** The relation between lupus and tubercle, 534.
- Lynch, G. H.** Chorea as a hysterio-neurosis, 274.
- Macdonald, J. N.** Historical notes on the discovery of the nasal erectile tissue, 1.
- Malaria.** The limitations of quinine in malaria, 187.
- Marriages.** The effect of consanguineous marriages upon offspring. Huntington, C. F., 312.
- Massachusetts.** The Governor of Massachusetts upon the State's medical examinations, 29; Massachusetts health report, 136; Massachusetts health again a victim to lunacy and charity, 585.

**Materia Medica and Therapeutics.** Phenol-camphor, Schaefer, T., 32; saccharated oxide of iron, Walton, G. L., 34; mania, 42; new remedies: euphorbia pulifera, 66; a new mode of using an old remedy: chloroform water, 92; cocaine discs, Wrenn, J. W., 103; foreign bodies in the esophagus treated by apomorphia, Preble, W., 107; Monse's iron in diarrhoea, Williams, E. T., 127; cocaine in urethrotomy, Garland, G. M., 127; cocaine in the dilatation of urethral strictures, Dixon, R. B., 202; the use of ether in puerperal eclampsia, Reynolds, J. F., 205; electricity as a stimulus in cardiac and respiratory failure, Griswold, C., 231; the germ theory of disease in its relation to therapeutics, 234; oleate of cocaine, Squibb, E. R., 255; antiseptic recipes, 262; cocaine for sleeplessness, Woodman, W., 287; researches on the physiological, chemical, and therapeutic properties of hamamelis virginica, Gray, H., 333; antipyretic and its effects, Draper, W. H., 385; corrosive sublimate injections, Richardson, W. L., 413; the influence of chlofuga racemosa upon parturition, Knox, J. S., 451; some remarks on the value of permanganate of potash in amenorrhoea, Dearing, E. J., 457; therapeutics judged by statistics, 462; the limitations of quinine in malaria, 487; quality of some of the pharmacological drugs in common use, Davenport, B. F., 500; tenicide therapeutics, 510; antiseptic inhalations, Robinson, B., 552; peroxide of hydrogen as a medicine: its use in larval and ophthalmic practice, Wetman, E., 555; treatment of chronic bronchitis and asthma with apomorphia, Webster, G. W., 555; diphtheria and its treatment by calomel, Murray, S. J., 555; treatment of cerebral hemorrhage and embolism by the internal use of carbonate of ammonia, Van Wyck, R. J., 556; antiseptic surgery, Padlock, E. K., 560; the use of concentrated solutions of saline cathartics in dropsy, 585; tannate of mercury, Tilden, G. H., 608; stillingia, Bovolitch, V. Y., 608; a Massachusetts pharmacy law, 613; ad nicias, Williams, E. T., 638.

**Mattison, J. R.** The prevention of opium addiction with special reference to the value of galvanism for the relief of neuralgic pain, 442.

**Mears, J. E.** Phosphorus necrosis of the jaws, 437.

**Meetings.** Annual medical meetings, 583.

**Meligs, A. V.** Report of a case of occlusion of the vena cava superior and of a case of hepatic abscess, 349.

**Membranes.** Functions of the membranes in labor, Byford, H. T., 327.

**Memorial Window to Southern herosism,** 514.

**Merriam, A. G.** The treatment of patients in the temple of Esculapius, 304.

**Metaphysics and mind-healing,** 559.

**Michigan.** Geographical distribution of phthisis in Michigan, with sketch of topography, Sharley, E. L., 577.

**Milk.** The effect of cow's food, etc., upon the milk, 40; the amount of albuminoids in human milk, 560; report of the milk inspector of the city of Boston, 1-84-85, 514.

**Mills, C. A.** Longevity of statesmen and public officials, 513.

**Mind.** Insane criminals, 113; report of a case of monomania, Boland, E. S., 341; report on a case of insanity, Channing, W., 341; metaphysics and mind-healing, 559; the London Times on the mind-cure, 637.

**Mind-cure.** Metaphysics and mind-healing, 559.

**Misadventure.** Two cases of misadventure, Warren, E. W., 60.

**Mississippi Valley.** Sanitary council of the Mississippi Valley, 215.

**Monomania.** Report of a case of monomania, Boland, E. S., 341.

**Monse's Iron in Diarrhoea,** Williams, E. T., 127.

**Monsters.** Anencephalic foetus, Galvin, G. W., 252.

**Morris, M. A.** Contractions of pelvic hæmatoecle; one death, 243.

**Morse, H. L.** Report on otology, 54.

**Mundé, P. F.** Two cases of dangerous hæmorrhage from rupture of the vagina during first coitus, 471.

**Murray, S. J.** Diphtheria and its treatment by calomel, 555.

**Muscular Rickets.** Clinical and experimental muscular rigidity or Little's disease, Bradford, E. H., 217.

**Musser, J. H.** Hypertrophy of prostatic gland; chronic cystitis; cystic and cirrhotic kidneys; death from exhaustion, 132; tumor of bladder; enlarged third lobe of the prostate gland; retention of urine; fatal passage made by soft catheter; septic fever; death from exhaustion, 132.

**Myxodema.** A case of myxodema with atrophy of the optic nerves, Wadsworth, O. F., 5.

**Nervous Pigmentosus,** Schweinfelt, G. E. de, 227.

**Naucrede, C. R.** Specimens from excretion of the astragalus for caries, etc., 237.

**Nantucket.** The sanitary condition of Nantucket, Williams, H., 399, 430; the sanitary condition of Nantucket, Abbott, S. W., 357.

**Nasal Erectile Tissue.** Historical notes on the discovery of the nasal erectile tissue, Menzies, N. J., 1.

**National Library and Museum.** False economy toward the, 110.

**Neff, J. S.** A case of cardiac (?) aneurism, 299.

**Nervous System.** Cutaneous and deep reflexes, Knapp, P. C., 34; tendon reflexes of the arm of the catella, Walton, G. L., 34; pathology and treatment of delirium tremens, 19; brain surgery and vivisection, 67; degenerative ataxia of the spine, Putnam, J. J., 86; case of puerperal convulsions, Blood, R. H., 128; a new treatment of sciatia, 210; syphilis of the nervous system, Webster, S. G., 275; clonus as a hysterical phenomenon, Lyons, G. H., 271; some clinical observations on regard to new chorea associated with increased temperature of the part affected, Hare, H. A., 317; synostosis of the vertebral column, Roberts, A. S., 350; spindylitis of the dorsal vertebrae with tuberculous infection of the lungs, 353; Wolff's treatment of the spinal cord, 353; note on a hitherto unrecognized feature of the tetanus, Spitzka, E. C., 365; locomotor ataxia: Its diagnosis and treatment in the precatase stage, Brower, D. R., 375; the field and limitation of the operative surgery of the human brain, Roberts, J. B., 420; the prevention of opium addiction with special reference to the value of galvanism for the relief of neuralgic pain, Mattison, J. R., 442; nervous symptoms due to overlooked anomalies of the eye and ear, Gradle, H., 477; the basal pathology of chorea, Wood, H. C., 523; the treatment of sciatia, Pires, J. O., 537; treatment of cerebral hæmorrhage and embolism by the internal use of carbonate of ammonia,

Van Wyck, R. C., 556; report of a case of metastasis of acute rheumatism from the shoulder and arm to the meninges of the brain, resulting fatally, Wood, C. S., 557; Jacksonian epilepsy, Osler, W., 587; cases of cerebral symptoms in early (secondary) syphilis, Greenwood, F. B., 571, 585, 607.

**New York, 18.**

**New York.** Annual report of the New York State Board of Charities, 211, 405; the artificial ponds in the New York central park, 487.

**Noise as a factor in disease,** 258.

**Obstetrics.** Report on, Green, C. M., 101; new obstetric forceps and vaginal speculum, Schuyler, W. D., 108; an analysis of one thousand successive obstetrical cases, Driver, S. W., 57.

**O'Connell, P.** Missed abortion, 554.

**Oedema, coniparisons,** 655.

**Opium.** The physiology of "falling bodies," 535.

**Opium.** The prevention of opium addiction with special reference to the value of galvanism for the relief of neuralgic pain, Mattison, J. R., 442; death from overdose of opium, Cordeiro, F. J. R., 512.

**Orthopaxy.** Report of progress in orthopedic surgery, Bradford, E. H. and Burdell, H. L., 390; two cases of talipes, Taylor, C. F., 530; dorsal caries and suppurative disease of the hip, Sayre, L. H., 531; the management of the abscesses of hip disease, Judson, A. S., 531; double congenital displacement of the hip; description of a case with treatment resulting in cure, Brown, B., 541; a contribution to the mechanical treatment of diseases of the knee-joint, Stillman, C. F., 568; congenital displacement of the hip, 583.

**Osler, O.** Notes on the morbid anatomy of pneumonia, 406.

**Osler, W., Dr.** Darling's poem, 63; specimen of aneurism of the aorta with rupture into the trachea in two places and perforation of the esophagus, 480; Jacksonian epilepsy, 587.

**Otis, W. J.** Demonstration of position and length of the sigmoid flexure of the colon; and Houston's valves of the rectum, 606.

**Ovariectomy.** Five cases of ovariectomy, Elliott, J. W., 89, 167; mi-liferous ovaries, first, Homans, J., 158; spray in ovariectomy, Homans, J., 213.

**Ovary.** Dermoid cyst of the ovary, Elliot, J. W., 607.

**Padlock, E. K.** Antiseptic surgery, 563, 591.

**Pancreas.** Death from hæmorrhage into the pancreas, Reynolds, J. P., 349.

**Parasites.** Tænia solium in a child two years of age, Davis, C. G., 281; increased frequency of scabies, Greenwood, F. B., 619.

**Paris.** Paris letters. Medical matters in Paris, 547, 562, 588.

**Parkes, C. T.** A case of cholelithostomy, 437.

**Parkinson, J. H.** A consideration of extravagance in the use of ether, 465.

**Pathology.** Recent progress in pathology and pathological anatomy, Whitney, W. F., 524, 537.

**Pelvis.** A case of pelvic abscess following childbirth, Forster, E. J., 189, 203; three cases of pelvic hæmatoecle, one death, Morris, M. A., 243, 252.

**Pennsylvania.** State regulation of medical practice in Pennsylvania, 21.

**Penny, W. A.** Retained placenta, 15.

**Penny, Dinners and Overpressure,** 236.

**"Pericnious" Anæmia.** A case of "pericnious" anæmia: recovery, Shattuck, G. B., 2, 16.

**Pharmacomania,** 42.

**Phenol-camphor.** Schaefer, T., 32.

**Phosphorus Necrosis of the Jaws.** Mears, J. E., 437.

**Phthisis.** The home treatment of consumption, Shattuck, F. C., 576; geographical distribution of phthisis in Michigan, with sketch of topography, Sharley, E. L., 577; the results of the home treatment of phthisis compared with those of changed residence and climate, Hudson, E. D., Jr., 578.

**Phymosis.** Congenital phymosis and its consequences, Welchell, H. G., 52.

**Physiology.** Historical notes on the discovery of the nasal erectile tissue, Menzies, N. J., 1; some points in the physiology and pathology of the chest, shown by frozen sections, Dwight, T., 528; the necessity of admitting a vital principle, Dwight, T., 549.

**Pires, J. O.** The treatment of sciatia, 537.

**Placenta.** Retained placenta, Penny, E. W., 15; a case of placenta previa; delivery by version, Whitman, R., 59.

**Platt, J. H.** The problem of acclimatization, 577.

**Plumbing.** The principles of sanitary plumbing, Putnam, J. P., 385, 409, 439, 448.

**Pneumonia.** Further consideration of pneumonic differentiation, with special reference to the pneumatic cabinet, Williams, H., F., 576.

**Pneumonia.** Notes on the morbid anatomy of pneumonia, Osler, O., 406; two attacks of asthenic pneumonia, the first followed by paratuberculosis, the second by typhoid symptoms, Ayer, J. R., 521, 528.

**Poisons.** A case of carbolic-acid poisoning, Draper, F. W., 9; prevention of death following the successful treatment of morphia poisoning by atropia, Forster, E. J., 267; lead-poisoning complicated with prolapse typhoid fever, Wadsworth, O. F., 319; a case of holomorph poisoning, Goodell, G. L., 322; poisoning from sarsaparilla (??) since Gallopou, C. W., 153; death from overdose of opium, Cordeiro, F. J. R., 512.

**Polypus.** Urethral polyp, Schweinfelt, G. E. de, 227.

**Portous, J. G.** Hypertrophy of the prostate gland, 557.

**Porter, C. E.** Compound fracture of the leg, 108; cases of compound fracture, 107.

**Porter, W. H.** Syphilitic pneumonia and phthisis, 397; some experiments and observations in reference to the diagnostic significance of epithelial cells when found in urine, 129.

**Post, A.** Urethral sonics, 255.

**Pennsylvania, 21.**

**Pennsylvania.** State regulation of medical practice in Pennsylvania, 21; the official register of physicians in Illinois, 65; state regulation of medical practice, 24; report on theory and practice of medicine, Shattuck, G. B., 396.

**Preble, W.** Foreign body in the esophagus successfully treated with apomorphia, 107.

**Pregnancy.** Affections connected with. Retained placenta, Penny, E. W., 15; nature and prevention of puerperal fever, Fuller, F. B., 15; a case of mural pregnancy, Byford, H. T., 37; placenta with calcareous deposits, Etheridge, 39; an analysis of one thousand successive obstetrical cases, Driver, S. W., 57.

- fibroids and general (tubercular) peritonitis, Fisher, H. M., 88; diseases of the Fallopian tubes. Their relations to uterine displacements and the use of pessaries, Wyke, W. G., 109; report on progress in gynecology, Davenport, F. H., 125; the use and abuse of Baker's and Felt's operations, Baker, W. H., 150; multilocular ovarian cyst, Romans, J., 158; unusual cases of vesico-vaginal and vesico-uterine fistula, Baker, W. H., 163, 204; observations on the cervix uteri, Hosmer, A., 204; three cases of hamatocoele, one death, Morris, M. A., 243; gradual reposition of an inverted uterus by a new contraindication, Chadwick, J. R., 289, 294; ten cases of removal of uterine tumors by laparotomy, Romans, J., 313, 318; rupture of the vagina during coitus, Chadwick, J. R., 413; uterine carcinoma of unusually rapid development, Abbott, S. L., 415; endometritis, operation for, H. pathology, diagnosis, and treatment, 416; some points in the surgery of hypertrophied prostate, Gouley, J. W. S., 434; a case of dermoid or piliferous tumor, with cure by spontaneous opening into the intestine, Allee, W. F., 445; some remarks on the value of permanganate of potash in amenorrhea, Doering, F. J., 452; two cases of dangerous hemorrhage from rupture of the vagina during first coitus, Munde, P. E., 471; fibroid tumor of the ovary, Romans, J., 476; double vagina, Green, C. M., 477; chronic prostates, Tilden, G. N. and Watson, F. S., 486; Emmet's operation for inverted cervix, under hydrochlorate of cocaine, Roeth, A. G., 527; hypertrophy of the prostate gland, Porterson, J. G., 557; the influence of sea-voyaging upon the genital uterine functions, 581; dermoid cyst of the ovary, Elliot, J. W., 607.
- Germ Theory of Disease.** 111. the germ theory of disease in its relation to the puerperia, 28.
- Gerrish, F. H.** Cases of urinary calculus, 6.
- Goodell, G. Z.** A case of iodiform-poisoning, 352.
- Gordon, General Gordon** from a medical point of view, 106.
- Gouley, J. W. S.** Notes on contracture of the bladder consequent on cystitis, 237; some points in the surgery of hypertrophied prostate, 434.
- Grady, H.** Nervous symptoms due to overlooked anomalies of the eye and ear, 177.
- Grand, F. S.** The case of General Grant, 284.
- Green, C. M.** Report on obstetrics, 101; double vagina, 477.
- Greenough, F. B.** Raised circular patches on the palmar surface, of over twenty years' duration, 81; cases of cerebral symptoms in infant (secondary) syphilis, 371, 399, 407; increased frequency of scabies, 419.
- Griswold, G.** Electricity as a stimulus in cardiac and respiratory failure, 241.
- Gross, S. W.** Nephrectomy: its indications and contra-indications, 323.
- Guggenberger, von.** Auto-Casus-section, 33.
- Guild, H. M.** Compound dislocation of the femur, 375.
- Guy, H.** Researches on the physiological, chemical, and therapeutic properties of humants virginica, 61.
- Gynecology.** Report on progress in gynecology, Davenport, F. H., 125.
- Ham, J. R.** Treatment of fractures of the femur without splints, 190.
- Hammetts Virginia, Guy, H.** 361.
- Hare, H. K.** Some clinical observations in regard to menorrhoea associated with increased temperature of the part affected, 317.
- Harvard University.** Annual report of the president and treasurer, 1883-84. The medical school, 257.
- Harvey's manuscript letters,** Steeving, E. H., 213.
- Haven, H. C.** Poor food at the Massachusetts Medical Society dinner, 639.
- Hays, M.** On the use of concentrated solutions of saline cathartics in dropsy, 585.
- Haze, H.** Eczematoid affections, Basworthy, F. H., 578.
- Helfenger, A. C.** Circular pavidon warts, 112.
- Hewitt, G. B.** The "uncontrollable" vomiting of pregnancy, 166.
- Holmes, W. B.** Report on medical chemistry, 201.
- Hinsdale, G.** Compound fracture of the leg and foot: amputation after one year's recovery, 131.
- Hollopeter, W. C.** Inverse type of temperature in typhoid fever with a report of two cases, 25, 35.
- Holmes, O. W.** Letter from Dr. O. W. Holmes to Dr. Fordyce Barker, 165.
- Romans, J.** Exploratory abdominal incisions, 19, 25; multilocular ovarian cyst, 158; spray in ovariotomy, 214; ten cases of removal of uterine tumors by laparotomy, 313, 318; fibroid tumor of the ovary, weighing twenty-two pounds, 1108; tumor of the thigh, weighing twelve pounds, carcinoma of the leg, 156.
- Home treatment of consumption.** Studies, F. O., 570; the results of the home treatment of consumption contrasted with those of changed residence and climate, Hudson, E. D., Jr., 578.
- Hosmer, F. H.** Use of cocaine in case of otitis, 128.
- Hudson, E. D., Jr.** Report on cases of recurrent fibroma of the breast at seven and eleven years of age, 28.
- Horse and buggy.** Are the doctor's horse and buggy his tools? 287.
- Hosmer, A.** Observations on the cervix uteri, 204; apparatus for washing out the bladder, 205.
- Hospital accommodation for contagious diseases,** 188.
- Hospital Construction.** Circular pavilion ward, Helfenger, A. C., 112.
- Hudson, E. D., Jr.** The physical examination of weak chests and differential diagnosis of the external form of early phthisis, 567; the results of home treatment of consumption contrasted with those of changed residence and climate, 578.
- Hudson, Mr. Dr. Hudson** a warning, Richardson, W. L., 190.
- Huddell, A.** A rule for the exact division of climate, based upon the average of the combined atmospheric barometrical. In the United States, 1883-84, 577.
- Hunter, J. R.** Endometrial fungus, its pathology, diagnosis, and treatment, 416.
- Hutchinson, J. C.** Address before New York State Medical Association, 10th district branch, 251.
- Hygiene, Health, and Boards of Health.** Investigation of the prevalence and inhibition of three hundred cases of typhoid fever, 1883-84, 16; the Massachusetts health report, 136; preparation of a health officer. 17; another health bill before Congress, 130; public health in West Virginia, 190; sanitary council of the Mississippi Valley, 215; discussion of the best sanitary and therapeutic measures for the prevention and control of epidemic cholera, Durkin, S. H., 224; the dangers of water-gas, 235; noise as a factor of disease, 238; report on public hygiene, Abbott, S. W., 209; the sanitary condition of Nantucket, Williams, H., 309, 420; the principles of sanitary plumbing, Putnam, J. P., 385, 409, 429, 437; the sanitary condition of Nantucket, Abbott, S. W., 385; the contagiousness of scarlet fever, 402; annual report of the New York State Board of Health, 403; overpressure at school as it affects girls, 404; the artificial ponds in the New York Central Park, 487; an epidemic of typhoid fever from contaminated sewage, 509; Massachusetts health again a victim to lunacy and charity, 585; Dr. H. F. Walcott and the Massachusetts Board of Health, 586; a health officer, 611; an instructorship of hygiene in the Boston public schools, 614.
- Hygroma Lingue,** Zeisler, J., 281.
- Hypnotism,** Hypnotic Chicago, 314.
- Hyrtl, Professor Hyrtl's jubilee,** 426.
- Ibid.** A new list, 308.
- Illinois.** The official register of physicians in Illinois, 65.
- Imprisonment of members of the Massachusetts Medical Society,** 628.
- Index Medicus,** 118, 305.
- Ingalls, E. F.** Empyema, paracentesis, and drainage, 376.
- Insane Criminals,** 113.
- Insane Hospitals.** Fires in insane hospitals, 169; business management of insane hospital, 210.
- Instruments and Apparatus.** New obstetric forceps and vaginal speculum, Schuyler, W. D., 198; apparatus for washing out the bladder, Hosmer, A., 205; vaginal douches, abdominal and vaginal coils, rubber tubing containing brass wire spiral, Chamberlain, M. L., 245; methral sounds, Post, A., 257; the electric light for apparatus of lithotomy, Baker, W. H., 294; a new and simple apparatus for testing the quantity of urea in the urine, Doyens, C. A., 324; the posterior splint for the forearm, Dulles, C. W., 513; a useful form of ligature, Lathrop, W. H., 562; a contribution to the mechanical treatment of diseases of the knee-joint, Stillman, C. F., 568; further consideration of pneumatic differentiation, with demonstration of the pneumatic cabinet, Williams, H. F., 556; the history of the Cammann stethoscope with the presentation of a modification of the Cammann stethoscope, Cammann, D. M., 579; Cammann's stethoscope, 580.
- Iodoform.** A case of iodiform-poisoning, Goodell, G. Z., 352.
- Ith.** Scabies in the army, Wilder, A. M., 68; army itch, White, J. C., 91.
- Jacksonian Epilepsy,** Osler, W., 587.
- Jacobi, A.** Inaugural address, 184.
- Jacobi, M. P.** Diptheria, 61.
- Janeway, E. G.** Cholera, 11; intestinal lesions of typhoid fever, 13; rare pathological specimens, 323; the advance in our knowledge of the pathology of disease, 579; specimens of ulcerative colitis, 581; a case of abscess of the liver, 581.
- Jarvis, W. C.** The aetiology and treatment of nasal catarrh, with special reference to deviated septum, 279; catarrhal affections of the nasal cavities as a cause of pulmonary phthisis, 553.
- Jedries, Dr. Jedries'** aerial voyage across the English channel in 1850, 61.
- Judson, A. S.** The management of the abscesses of hip disease, 531.
- Jurispredence.** Recent progress in forensic medicine, Draper, F. W., 154, 209.
- Keating, J. M.** The medical treatment of diptheria, 73; the climate of central Florida, 578.
- Kinner, R. O.** Cholera and its treatment by Dr. John Chapman's method, with twelve cases, 276.
- Klein, C. H.** von. Roller-skating, 331.
- Knap, P. C.** Cutaneous and deep reflexes, 34.
- Knee.** A contribution to the mechanical treatment of diseases of the knee-joint, Stillman, C. F., 568.
- Knox, J. S.** The influence of chlostridium racemosum upon parturition, 431.
- Koch's Cholera Bacilli,** Weidt, C. E., 108.
- Lachrymal Gland.** Slides from an adenofibroma of lachrymal gland, Schweinitz, G. E. de, 227.
- Laparotomy.** Ten cases of removal of uterine tumors by laparotomy, Romans, J., 313, 318.
- Lathrop, W. H.** A useful form of ligature, 562.
- Lawrence, R. M.** Old medical announcements, 262.
- Lecture System.** Thomas, F. S., 331.
- Legislation.** The fate of the Massachusetts medical bill, 615.
- Leprie, William H.** 81.
- Liberia.** Letter from Liberia, Roberts, J. H., 165.
- Ligature.** A useful form of ligature, Lathrop, W. H., 562.
- Listerism.** The results of Listerism in amputation of the breast, Gallagher, C. W., 352.
- Lithotomy.** Caswell, L. T., 15.
- Little's Disease.** Cases of congenital muscular rigidity, or Little's disease, Bradford, E. H., 217.
- Locomotor Ataxia.** Its diagnosis and treatment in the precathe stage, Brower, D. R., 375.
- Loth Priests,** 161.
- London.** Letter from London, 41; letter from our London correspondent, 164.
- Longstreth, M.** Alveolar sarcoma of the kidney, 206.
- Loups, A. L.** Address before American Climatological Association, 101.
- Lovett, E. W.** Letter from the Ashfordians, 117.
- Lowell, St. John's Hospital, Lowell,** 511.
- Lupus.** The relation between lupus and tubercle, 534.
- Lynch, G. H.** Cholera as a hydrophobic disease, 274.
- McKenzie, J. N.** Historical notes on the discovery of the nasal erectile tissue, 1.
- Malaria.** The influences of quinine in malaria, 187.
- Marrages.** The effect of consanguineous marriages upon offspring, Willingham, C. P., 312.
- Massachusetts.** The Governor of Massachusetts upon the State's medical examiners, 89; Massachusetts health report, 136; Massachusetts health again a victim to lunacy and charity, 585.

**Materia Medica and Therapeutics.** Phenol-acetophor, Schaefer, T., 32; saccharated oxide of iron, Walton, G. L., 547; pharmacocopia, 42; new remedies: euphorbia pulifera, 69; a new mode of using an old remedy: chloroform water, 92; cocaine discs, Warren, J. W., 165; foreign bodies in the esophagus treated by amorphous, Preble, W., 167; Monse's iron in diarrhoea, Williams, E. S., 127; cocaine in metrorrhoea, Gardner, G. M., 127; cocaine in the dilatation of urethral strictures, Dixon, R. B., 262; the use of ether in puerperal clampsia, Reynolds, J. P., 265; electricity as a stimulus in cardiac and respiratory failure, Griswold, G., 281; the germ theory of disease in its relation to therapeutics, 251; outline of cocaine, "quills," B. F., 555; antiseptic resins, 262; cocaine for sleeplessness, Woodman, W., 257; researches on the physiological, chemical, and therapeutic properties of hamamelis virginica, Guy, R. L., 361; antipyrin and its effects, Draper, W. H., 365; corrosive sublimate injections, Richardson, W. L., 413; the influence of chloroform racemose, upon parturition, Knox, J. S., 451; some remarks on the value of permanenate of potash in amenorrhoea, Doering, E. J., 455; therapeutics judged by statistics, 463; the limitations of quinine in malaria, 487; quality of some of the pharmacopoeial drugs in common use, Dayenport, B. F., 500; toulie therapeutics, 510; antiseptic inhalations, Robinson, B., 552; peroxide of hydrogen as a medicine: its use in aural and ophthalmic practice, Ilettman, B., 553; treatment of chronic bronchitis and asthma with amorphous, Webster, G. W., 554; diptheria, its etiology, pathology, and treatment, with the treatment of cerebral hemorrhage and embolism by the internal use of carbonate of ammonia, Van Wyck, J. R., 556; antiseptic surgery, Paddock, F. K., 565; on the use of concentrated solutions of saline cathartics in dropses, 587; tannate of mercury, Putnam, G. H., 587; stillbirths, Gardner, G. M., 588; a Massachusetts pharmacy law, 613; ad uncias, Williams, E. T., 628.

**Mattison, J. R.** The prevention of opium addiction with special reference to the value of galvanism for the relief of neuralgic pain, 442.

**Mearns, J. E.** Phosphorus necrosis of the jaws, 437.

**Meetings.** Annual medical meetings, 583.

**Meigs, A. V.** Report of a case of occlusion of the vena cava superior, and of a case of heart-tumor, 79.

**Membranes.** Functions of the membranes in labor, Byford, H. T., 39.

**Memorial Window to Southern heroism, 514.**

**Merrill, A. G.** The treatment of patients in the temple of Esculapius, 304.

**Metaphysics and mind-healing, 559.**

**Mitcham, C.** Geographical distribution of phthisis in Michigan, with sketch of topography, Shurley, E. L., 577.

**Milk.** The effect of cow's food, etc., upon the milk, 40; the amount of albuminoids in human milk, 500; report of the milk and butter of the city of Boston, 184-85, 516.

**Mills, C. A.** Longevity of statesmen and public officials, 513.

**Mind.** Insane criminals, 113; report of a case of monomania, Boland, E. S., 341; report on care of the insane, Channing, W., 341; metaphysics and mind-healing, 559; the London Times on the mind-cure, 647.

**Mind-cure.** Metaphysics and mind-healing, 559.

**Miscarriage.** Two cases of miscarriage, Warren, E. W., 40.

**Mississippi Valley.** Sanitary council of the Mississippi Valley, 215.

**Monomania.** Report of a case of monomania, Boland, E. S., 341.

**Monse's Iron in Diarrhoea, Williams, E. T., 127.**

**Monsters.** Anencephalic foetus, Galvin, G. W., 252.

**Morris, M. A.** Three cases of pelvic hematocoele; one death, 213.

**Morse, H. L.** Report on otology, 54.

**Morris, H. F.** Two cases of dangerous hemorrhage from rupture of the vagina during first coitus, 471.

**Murray, S. J.** Diptheria and its treatment by calomel, 555.

**Muscular Rigidity.** Cases of congenital muscular rigidity or Little's disease, Bradford, E. H., 217.

**Musser, A. H.** Hypertrophy of prostatic gland; chronic cystitis; cystic and cribrate kidneys; death from exhaustion, 182; tumor of bladder; enlarged third lobe of the prostate gland; retention of urine; false passage made by soft catheter; septic fever; death from exhaustion, 182.

**Myxodema.** A case of myxodema with atrophy of the optic nerves, Wadsworth, O. F., 5.

**Necrosis Pigmentosa, Schwabitz, G. E. de, 227.**

**Narcocede, C. B.** Specimens from excision of the astragalus for osteitis, etc., 237.

**Nantucket.** The sanitary condition of Nantucket, Williams, H., 369, 450; the sanitary condition of Nantucket, Abbott, S. W., 357.

**Nasal Erectile Tissue.** Historical notes on the discovery of the nasal erectile tissue, Mackenzie, J. N., 1.

**National Library and Museum.** Public economy toward the, 110.

**Neill, J. S.** A case of cardiac (?) aneurysm, 209.

**Nervous System.** Cutaneous and deep reflexes, Knapp, P. C., 34; tendon reflex after fracture of the patella, Walton, G. L., 34; pathology and treatment of delirium tremens, 19; brain surgery and vivisection, 19; the treatment of the spinal cord, Putnam, J. J., 85; case of puerperal convulsions, Blood, R. H., 128; a new treatment of scabies, 210; syphilis of the nervous system, Webster, S. G., 273; chorea as a hystero-neurosis, Lyman, G. H., 271; some clinical observations in regard to monochromasia associated with increased temperature of the part affected, Hays, H., 317; synostosis of the vertebral column, Roberts, A. S., 350; spurious ribs of the dorsal vertebrae with miliary tuberculosis of the lungs, 351; Wolf's treatment of "writer's cramp," 353; note on a hitherto unrecognized feature of the tegumentum, Schaefer, E. C., 365; locomotion in mania, its control by the eye and ear, Gray, J. H., 371; 477; the basal pathology of chorea, Wood, H. C., 323; the treatment of scabies, Pires, J. O., 537; treatment of cerebral hemorrhage and embolism by the internal use of carbonate of ammonia,

Van Wyck, R. C., 556; report of a case of metastasis of acute rheumatism from the shoulder and arm to the arachnoid of the brain, resulting fatally, Wood, C. S., 557; Jacksonian epilepsy, Osler, W., 587; cases of cerebral symptoms in early (secondary) syphilis, Greenough, F. B., 571, 585, 607.

**New Year, 18.**

**New York.** Annual report of the New York State Board of Charities, 211, 407; the artificial ponds in the New York central park, 487.

**Noise as a factor of disease, 238.**

**Obstetrics.** Report on, Green, C. M., 101; new obstetric forceps and vaginal speculum, Schuyler, W. D., 108; an analysis of one thousand successive obstetrical cases, Driver, S. W., 57.

**O'Connell, P.** Missed abortion, 554.

**Odious comparisons, 635.**

**Odium.** The physiology of "falling bodies," 553.

**Opium.** The prevention of opium addiction with special reference to the value of galvanism for relief of neuralgic pain, Mattison, J. R., 442; death from overdose of opium, Cordeiro, P. J. R., 512.

**Orthopaedics.** Report of progress in orthopaedic surgery, Bradford, E. H. and Burrell, H. L., 390; two cases of talipes, Taylor, C. F., 530; dorsal caries and suppurative disease of the hip, Sayre, L. L., 531; the management of the abscesses of hip disease, Judson, S. S., 531; double congenital displacement of the hip; description of a case with treatment resulting in cure, Brown, B., 541; a contribution to the mechanical treatment of diseases of the knee-joint, Robinson, C. F., 541; congenital displacement of the hip, 553.

**Osler, O.** Notes on the morbid anatomy of the stomach, 587.

**Osler, W.** Dr. Darling's poem, 648; specimen of aneurism of the aorta, with rupture into the trachea in two places and perforation of the esophagus, 480; Jacksonian epilepsy, 587.

**Ovariotomy.** Five cases of ovariotomy, Elliott, J. W., 56, 107; sub-umbilic ovarian cyst, Homans, J., 158; spray in ovariotomy, Homans, J., 213.

**Ovary.** Dermoid cyst of the ovary, Elliott, J. W., 507.

**Paddock, F. K.** Antiseptic surgery, 565, 591.

**Pancreas.** Death from hemorrhage into the pancreas, Reynolds, J. P., 275.

**Parasites.** Tenia solium in a child two years of age, Davis, C. G., 284; increased frequency of scabies, Greenough, F. B., 610.

**Paris.** Paris lectures. Medical matters in Paris, 574, 562, 588.

**Parkes, C. T.** A case of cholecystitis, 437.

**Parkinson, J. H.** A consideration of extravagance in the use of ether, 466.

**Pathology.** Recent progress in pathology and pathological anatomy, Whitney, W. F., 524, 567.

**Pelvis.** A case of pelvic abscess following childbirth, Forster, E. J., 199, 203; three cases of pelvic hematocoele, one death, Putnam, M. A., 213, 252.

**Pennsylvania.** State regulation of medical practice in Pennsylvania, 21.

**Penny, E. W.** Retained placenta, 15.

**Penny Dimers and Overpressure, 226.**

**Pernicious Anemia.** A case of "pernicious" anemia; recovery, Shattuck, G., 2, 10.

**Pharmacomania.** Schaefer, T., 32.

**Phenol-amphor.** Schaefer, T., 32.

**Phosphorus Necrosis of the Jaws.** Mearns, J. E., 437.

**Phthisis.** Geographical distribution of phthisis in Michigan, with sketch of topography, Shurley, E. L., 577; the results of the home treatment of consumption contrasted with those of changed residence and climate, Hudson, E. D., Jr., 578.

**Physiology.** Congenital phthisis and its consequences, Wetherill, H. G., 52.

**Physiology.** Historical notes on the discovery of the nasal erectile tissue, Mackenzie, J. N.; some points in the physiology and pathology of the chest, shown by frozen sections, Dwight, T., 528; the necessity of admitting a vital principle, Dwight, T., 549.

**Pires, J. O.** The treatment of scabies, 537.

**Placenta.** Retained placenta, Penny, E. W., 15; a case of placenta previa; delivery by version, Whitman, R., 30.

**Platt, J. A.** The problem of acclimatization, 577.

**Plumbing.** The principles of sanitary plumbing, Putnam, J. P., 385, 406, 429, 448.

**Pneumate.** Further consideration of pneumatic differentiation, with demonstration of the pneumatic cabinet, Williams, H. F., 576.

**Pneumonia.** Notes on the morbid anatomy of pneumonitis, Osler, O.; pneumonia; adenitis; pneumonia; pneumonia; pneumonia; by paratuberculosis, second by typhoid symptoms, Ayer, J. B., 521, 528.

**Poisons.** A case of embolism poisoning, Draper, E. W., 9; premature birth following the successful treatment of morphia poisoning by atropia, Forster, E. J., 267; lead poisoning complicated with probable typhoid fever, Wadsworth, O. F., 249; a case of iodoform poisoning, Goodell, G. Z., 352; poisoning from sarsaparilla (?) soda, Galloppe, C. W., 473; death from overdose of opium, Cordeiro, F. J. R., 512.

**Preble, W.** Cerebral abscess, Schwabitz, G. E. de, 227.

**Pretorius, A.** The pathology of the placenta, 557.

**Porter, C. B.** Compound fracture of the leg, 198; cases of con servative surgery, 224.

**Porter, W. H.** Syphilitic pneumonia and phthisis, 397; some experimental observations in reference to the diagnostic significance of epithelial cells when found in urine, 429.

**Post, A.** Urethral sound, 275.

**Practice of Medicine.** State regulation of medical practice in Pennsylvania, 21; the official register of physicians in Illinois, 65; state regulation of medical practice in New York, 21; report on theory and practice of medicine, Shattuck, G., 2, 10.

**Preble, W.** Foreign body in the esophagus successfully treated with amorphous, 167.

**Pregnancy.** Affections connected with. Retained placenta, 15; retention of placenta and prevention of puerperal fever, Fuller, F. B., 15; a case of mural pregnancy, Byford, W. H., 47; placenta with calcareous deposits, Etheridge, 39; an analysis of one thousand successive obstetrical cases, Driver, S. W., 57.

- [illegible]

**Torture.** A question of torture, 259.

**Tubercle bacillus.** The tubercle bacillus: its morphology, mode of development, its life history; its results in the human organism; its detection; the culture of the tubercle bacillus, 259, 265.

**Tuberculosis.** Cases of tuberculosis, 131.

**Tuberculosis.** Cases between lupus and tubercle, 534.

**Tumors.** A case of abdominal tumor, Richardson, W. L., 76; fibroid tumor of the ovary, weighing twelve pounds; sarcoma of the thigh, weighing twelve pounds; sarcoma of the leg, 76.

**Homans, J. C., 74.** The selection of a suitable climate for the various forms of pulmonary consumption, 317, 555.

**Typhoid fever.** Intestinal hemorrhage, 131.

**Typhoid fever.** The premises and habitations of three hundred cases of typhoid fever, Swarts, G. T., 16; an epidemic of typhoid fever from contaminated sewage, 509; the influence of temperature in typhoid fever, with a report of two cases, Holthrop, W. C., 28, 35; the period of incubation of typhoid fever, Shattuck, E. C., 36.

**Typhoid fever.** Pyelonephritis and chronic parenchymatous nephritis in the same patient, complicating cystitis, 238; sarcoma of retro-peritoneal glands, 301.

**Uric acid.** A peculiar form of uric-acid precipitate, Ellis, F. W., 131.

**Urinary System.** Cases of urinary calculi, Gerrish, F. H., 61; repeated lithotomy, Caswell, E. T., 13; remarks upon chronic contracted kidney, with normal urine, Wood, H. C., 49; congenital pyelonephritis and its consequences, Wetherill, H. G., 52; case of diffuse nephritis and amyloid degeneration of the kidneys, complicated, toward the close of life, with diabetes mellitus and anasarca, Wood, E. S., 123, 131; remarks and observations in reference to a new histologic significance of epithelial cells when found in the urine, Porter, W. H., 129; hypertrophy of prostatic gland; chronic cystitis; cystic and chrystic kidney; enlarged third lobe of the prostate gland; retention of urine; false passage made by soft prostatic gland; retention of urine; death from exhaustion, Musser, J. H., 132; cases of retention of urine; death from exhaustion, Musser, J. H., 132; cocaine in the dilatation of urethral stricture, Hosmer, A., 205; 207; apparatus for washing the bladder, Longstreth, M., 206; urethral alveolar sarcoma, Schwelnitz, G. E. de, 227; pyelonephritis and chronic pyelitis, Schwelnitz, G. E. de, 227; pyelonephritis complicating chronic parenchymatous nephritis in the same patient, complicating cystitis, Tyson, A., 228; notes on contracture of the bladder, consequent on cystitis, Gaudin, J. A., 252; urethral sounds, Post, A., 253; cases of chronic abscess dependent on urethral stricture, Pathol., H. L., 253; the constrictor urethrae made of its relations to pathology and treatment, Cabot, A. C., 254; penicillin in urology and treatment, Ellis, F. W., 259; nephrectomy: its indications and contraindications, Gross, S. W., 423; nephrothotomy, Wilbur, L. M., 423; some points in the surgery of hypernephroma, Gouley, J. W. S., 434; incontinence of urine in the suprapubic prostate, Gouley, J. W. S., 434; incontinence of urine in children, Smith, J. L., 449; cases of abscess of the prostate gland in children, Bruen, E. P., 450; cases of abscess of the prostate gland in children, Bruen, E. P., 450; primary tuberculosis of the kidneys, Fussell, Watson, F. S., 450; primary tuberculosis of the kidneys, Fussell, Watson, F. S., 450; hypertrophy of the prostate gland, Porteous, J. G., 537.

## HISTORICAL NOTES ON THE DISCOVERY OF THE NASAL ERECTILE TISSUE.

BY JOHN S. MACKENZIE, M.D., OF BALTIMORE, MARYLAND,  
Surgeon to the Baltimore Eye, Ear, and Throat Charity Hospital.

It is generally supposed that to Kohlransch is due the honor of discovery of the erectile tissue of the nose, — a supposition to which nearly all writers steadfastly adhere, — and I have been taken to task by one of my German confrères for ignoring the alleged claims of that writer to priority in the matter.

My reasons for so doing will be readily understood when the following historical facts are taken into consideration. These are the result of an extensive study of the anatomical literature of the nasal passages, and only those works have been cited whose authors appear entitled to the credit of original or independent observation.

The porous and spongy character of some portions of the nasal mucous membrane seems to have attracted the attention of certain writers of the seventeenth century,<sup>1</sup> and Schneider,<sup>2</sup> whose graphic description led Haller to christen it the Schneiderian membrane, depicted it as made up of a congeries of vascular tufts, but failed to recognize its true cellular structure. The first reference to the latter that I can find is contained in an inaugural dissertation by Benedict Ruppert,<sup>3</sup> who gives a very good description of it in the following words: "Huic dein perioste tunica nostra pituitaria superexpansitur, non tamen immediate; subtilis enim textum cellulare (quod, si scalpellò tunice pituitariæ vulnusculum indigitur, inque hoc aer inflatur, intumescit) intermediat periosteum inter & membranam pituitariam."

Later on we find a more explicit account of the tissue by Duverney.<sup>4</sup> Referring to the spongy structure covering the interior of the bony nose, he compares it to a network of interlacing veins and arteries intimately connected with the periosteum, and adds: "Si l'on souffle par la veine qui sort par le trou du troisième os de la mâchoire, l'on verra que cette membrane s'enfle et se soulève principalement dans la partie postérieure du nez, à peu près comme quand on souffle dans la rate."

It is, however, probable that the cellular nature of the membrane was known even before the time of the writers referred to, for I find in A System of Anatomy<sup>5</sup> published in Edinburgh in 1781, and which is simply a compilation from the works of Monro, Winslow, Innes, and others, the following passage: —

"All the other parts of it (i. e., the mucous membrane) in general are spongy and of different thickness. The thickest parts are those on the septum narium, on the whole lower portion of the internal nares, and on the concha; and if we make

a small hole in it at any of these places, and then blow through a pipe, we discover a very large cellular substance," etc.

The first, however, to distinctly announce its true erectile nature, seems to have been Cruveilhier,<sup>6</sup> who, in the second edition of his great work, published in 1845, observes: "La pituitaire est généralement plus épaisse que les autres membranes muqueuses; aussi est-il extrêmement facile de déterminer la structure éminemment vasculaire et véritablement érectile de cette membrane: Si on pique la pituitaire avec un tube à injection lymphatique rempli de mercure, ce liquide pénètre immédiatement dans les cellules du tissu érectile, et s'écoule de là par les veines qui y abondissent. Si on pique plus superficiellement, on voit se former un réseau lymphatique admirable, et tellement superficiel, que le mercure présente tout son éclat métallique. Ce réseau lymphatique ne communique nullement avec les cellules dont je viens de parler."

Eight years later appeared the often quoted, but rarely read, communication of Kohlransch.<sup>7</sup> This observer injected the tissue from the jugular vein, and looked upon it as a cavernous network of veins placed perpendicularly to and just underneath the mucous membrane. Such a plexus had been previously briefly referred to by Hyrtl,<sup>8</sup> and was subsequently claimed as an independent discovery by Kölliker.<sup>9</sup>

While due praise should be accorded to Kohlransch for original investigation, both his description and the figures which illustrate it show clearly that, in mistaking the erectile cells for cross-sections of venous trunks, he failed to appreciate the true erectile or contractile character of the tissue, which was subsequently set forth by Bigelow.<sup>10</sup> The latter observer, in an article familiar to the readers of this journal, described the tissue with great accuracy, and showed that it was limited to the space occupied by the superior and inferior turbinate bones and the septum. Apart from independent discovery, to Bigelow belongs the credit not only of giving the best description of this tissue, and of more accurately defining its minute structure and extent of distribution, but also of showing that the so-called mucoperiosteum of the posterior part of the septum is in reality an erectile substance. Bigelow was also the first to observe the alternate inflation and collapse of these bodies, which he compared to that of the lungs of a small animal, thereby leading the way to the rational interpretation of nasal affections. From their resemblance to the cavernous bodies of the penis Bigelow gave them the name of turbinate corpora cavernosa, but as Henle and, more recently, Zuckerkandl<sup>11</sup> have pointed out, they may be with more propriety classed among the contractile as contra-distinguished from the erectile tissues.

Finally Woakes<sup>12</sup> calls attention to the following passage in Toynbee's work on Diseases of the Ear: —

"Many years ago I pointed out the peculiar erectile tissue of

<sup>1</sup> See especially G. Rollius, *Dissertationes Anatomicae*, Noribergae, 1656, lib. ii, cap. 26.

<sup>2</sup> De Catarrhis, Witte-burgae, 1661-62, lib. v, passim.

<sup>3</sup> Diss. inaug. med. de tunica pituitaria, ejus anatomia, physiologia, et pathologia exposita. Vetero-Praque, 1754, Pars I, p. 22. The method of inflation seems to have been adopted at an early date, Winslow and others having demonstrated a glandular structure (erectile cells?) by this means.

<sup>12</sup> Deafness, Giddiness, and Noises in the Ear. Phil. ed., 1880, p. 40.

which the nasal mucous membrane is composed, not only in man but in most mammalia; this tissue is a most efficient respirator.\*

As pertinent to the subject of the present inquiry I would like to call attention to the description by Morgagni<sup>1</sup> of the "peculiar and red thicknesses of the membrane of the nostrils" found on the inferior turbinated bones, which is given with the singular accuracy which characterizes all the researches of that great anatomist. Describing the post-mortem appearances in an insane man, he says:—

"I saw that these thicknesses where they lay on the lower part of the inferior turbinated bones had grown out into very long caruncles which hung from each of these bones. And upon cutting into these excrescences, in any part whatever, I found them to be so constructed that between a white network, or, if you please, betwixt white cancelli, red areas seemed to be contained; which appearance confirmed the glandular nature of these thicknesses," etc.

Farther on he describes the millet-seed appearances and ashy-gray color of these masses in other bodies with such fidelity to nature that it leaves no doubt that these so-called glandular enlargements were none other than the hypertrophied turbinated bodies.

Morgagni thus narrowly missed the discovery of the turbinated erectile tissue and the relation of its enlargement to nasal disease.<sup>2</sup>

Note. It is only within a comparatively recent period that the hypertrophic enlargements of the turbinated tissues have been relegated to their proper anatomical place among affections of the nasal passages. The ancients probably knew of their existence, but confounded them with polypi: the Greeks under the terms "hypersarcosis" and "sarcoma," the Romans under the appellations "carnis excrecentia" and "germinatio." It is unnecessary to invoke the long list of ancient writers from Hippocrates down, in defence of this proposition, but I will simply direct attention to the following words of Aetorius as a fair presentation of the doctrine of his day: "Polypus, est meatuum, qui à colatu *improprie* (quasi dixeris coloratorios) vocatur, obstructio, propter carnis excrecentiam, quæ ea parte ita inhaeret, ut aegrè detrahi possit. Enasentur enim frequentes germinationes, quæ instar polyporum, nasi meatibus circumcirca adhaere adherent quibus inspiratio expiratioque prohibetur, et siquid superne pituita aut muci deluit haud facile obstante polypo delabi potest."<sup>3</sup>

A distinction was made by some<sup>4</sup> between true polypus and other "caruncles" found in the lower and more fleshy (carnissimæ) portions of the nose, and Janus<sup>5</sup> draws an accurate differential parallel between "ganglia" (evidently the hypertrophic

turbinated tissue of the present day) and polypi in the following sentences: "Credo vero differentiam, posse inde hauriri; primo ganglia semper deprehenduntur in aurium partibus inferioribus. Polypus vero frequentius subnascitur in partibus superioribus; dein circa basin semper sunt crassiora atque latiora; contra polypus magis est attenuatus imò sæpissime penilis. Tertio ganglia sunt duriora. Polypus vero mollior. Cancerosus vero atque durus distinguitur à ganglio, quod ganglion ut plurimum retineat colorem eundem cum partibus vicinis; polypus contra aut nigrescat aut colore præditus sit livido."

## A CASE OF "PERNICIOUS" ANÆMIA.—RECOVERY.<sup>6</sup>

BY GEORGE B. SHATTUCK, M.D.,  
Visiting Physician Boston City Hospital.

A. McL., the patient, a male, single, thirty-eight years old, of late a farmer by occupation, entered the City Hospital July 8th, 1884. He had been for many years a sailor. Patient's parents were reported to have both died of phthisis; his brothers and sisters, three in number, are all believed to be well. He had never been sick since he was a child until two years previously, when he was laid up in the marine hospital at Pensacola with fever and ague, which he called Texas fever. Had no chill since. No history of rheumatism or syphilis could be elicited. He had never been a hard drinker. Had not been subjected to any especial exposure, hardships, or mental worry. He gave up work on a farm a month before entering the hospital, feeling run down, and having lost his appetite, as he thought, from working a little too hard. About two weeks after giving up work, and the same length of time before coming under my care, began to have nose-bleed, sufficiently obstinate at times to necessitate plugging. He took to his bed ten days before entrance. The nose was plugged when entering the hospital.

He reported having had a cough for three months, with slightly viscid expectoration, a poor appetite, regular bowels, no headache. He had a temperature of 100° F., and a pulse of 101. A physical examination of the lungs showed dullness, bronchovesicular respiration, and a moderate number of fine and medium moist râles over the lower third of right back. The examination of the heart gave a negative result. The spleen was enlarged, though not greatly so. The urine was normal. There were no enlarged glands. The general appearance of the patient showed great emaciation and extreme pallor. He was very weak.

A diagnosis of phthisis was made, and he was put upon malt and oil, and tincture of chloride of iron.

A week after entrance râles were found in the lower left as well as the lower right back. He had gained a little strength, however, thought he felt better, and sat up somewhat. The next day he had epistaxis, which was promptly checked by plugging. Two days after thought he felt better, and began to sit up again. The oil distressed the stomach, and was omitted, malt being given without it.

Two weeks after entrance began to complain of

<sup>1</sup> De sedibus et causis morborum, lib. I. epist. XIV. art. 26. (I quote from the translation of Alexander in the London edition of 1726.)

<sup>2</sup> Curiously enough, many years before, the development of certain forms of polypus has been compared to the augmentation in bulk of the ciliares. Thus, Janus (De polypo, aurium, Lipsiæ, 1672, member 1, cap. II. § 2), in describing the variety known as *excrecentia, ciliæ, ciliæ*, in fine definitione nasalium, "excrecentia per quam cupio intellectum talen partem maxillarem, quæ nullo quidem naturali, nempe per appositionem alimen alaudabilis est, interion tamen desinit in quantitate ciliæ partes longe sub proportionem excedentem. Quæ maxillæ semper morbum parit proprioque excedentem. Exempla est, mentis oculi, ciliæ, ciliæ dicta," etc. Further on (§ 6) he compares the polypoid enlargements to the hypertrophy of the virgin hairs, "quæ maxillæ semper palam potest præse illius necesse dicitur."

pain in the right ear, from which a day or two later there was a slight discharge, at first serous, and subsequently bloody. July 25th, seventeen days after entrance, half a drachm of fluid extract of ergot was ordered every four hours. Three days later the bleeding from the right ear began. The ergot and malt were omitted on this day, July 28th, by Dr. F. W. Draper, who saw the patient in my absence, and he was given instead half an ounce of sherry every two hours, and three drops of Fowler's solution three times a day. At this time he had not been out of bed for a week. The pallor, debility, and distaste for nourishment had steadily increased; diarrhoea had been troublesome; there was oedema; he was steadily and rapidly failing; moreover, he had grown so deaf that he could understand almost nothing said to him.

July 30th, at my request, the blood was examined by Dr. W. L. Munro, the house officer, with Gower's hæmacytometer, showing as a mean of four enumerations only 595,000 red corpuscles to the cubic mm., the normal number being about 5,000,000.

August 1st. Dr. O. F. Wadsworth, by request, examined the fundus of the eye with the ophthalmoscope and reported the following conditions: Left eye.—The disc pale, central vessels of good size, very pale—both arteries and veins. Numerous hemorrhages scattered all about the retina, some of considerable size. Right eye.—Upper third of the disc obscured by hemorrhage. The spleen was examined again and found less enlarged than before. The Fowler's solution was increased to five minims three times daily, and was ordered to be increased two minims every other day until eight minims three times daily was reached.

By August 3d, the deafness had decreased considerably, the hearing was better; the patient felt better and took more interest in his surroundings. A soft systolic murmur was detected over the apex of the heart; the moist râles continued in both lower backs, and the dulness over the lower third of the right back.

August 5th. He began to sit up again.

August 10th. He was ordered twenty minims of chloride of iron in addition to the arsenic, and Tarragona instead of sherry wine.

August 13th. Two weeks after the first blood count, and fifteen days after the administration of arsenic, the hæmacytometer showed 1,180,000 red corpuscles to the cubic mm. The patient's general condition steadily and rapidly improved.

August 18th. He was up, dressed, and about the ward; six days later he went out about the yard.

August 28th. There were 3,025,000 red corpuscles to the cubic mm. The proportion of white to red corpuscles was at times somewhat increased, but was never more than relatively increased. September 19th he was discharged greatly improved. There was no count of the globules, the hæmacytometer being broken.

An ophthalmoscopic examination at this time, made by Dr. Myles Standish, showed both nerves to be paler than normal, and the fundus of each eye to be very light for a man with a dark complexion. In the left eye there was a large retinal hemorrhage immediately below the macula.

Since leaving the hospital the patient has been living and working on a farm at Dedham. He has gained steadily in strength and weight, and is as strong and heavy as he ever was in his life. No examination of the blood was made when I saw him to-day, December 22d, as his appearance and feeling of vigorous health made it unnecessary. The signs at the base of the right lung have disappeared. The local pulmonary process may have had some influence upon the temperature, otherwise but little upon the general condition. The temperature varied from 97.5° F. to 103° F., and the pulse from 75 to 120. The hemorrhages, though aggravating his condition, must be regarded as a result rather than as a cause, for the first one did not occur until two weeks after he had given up work on account of weakness and loss of appetite. Moreover, the amount of blood lost in this way whilst in the hospital was small, the epistaxis being promptly checked by plugging; and yet the unfavorable elements of the situation increased in the most threatening manner until the administration of arsenic.

The first diagnosis of phthisis was a correct one, but the pulmonary process was not the cause of the anemia and the prostration. In fact, a careful physical and oral examination of the patient and revision of his history fails to offer any satisfactory explanation for these extreme conditions which were apparently due to some change in the blood itself. Other than the consolidation in the lower right lung and the moderate enlargement of the spleen, no organic disease could be discovered, and the subsequent course of the case would indicate quite positively that none had been overlooked.

The patient had been living a fairly wholesome life in a healthy neighborhood, where he has since thriven. His habits were correct, there was no evidence of specific taint, his mind had been at ease, and, as a male, he had not been exposed to a rapid succession of pregnancies. There was nothing in the past history to account for the extremities to which he was so rapidly reduced, except the malarial attack at Pensacola two years before. This, the subsequent history, comparative good health and absence of chills, would hardly permit us to accept as an adequate explanation.

I therefore do not hesitate to call the anemia idiopathic; that it was pernicious, the hemorrhages nasal, aurial, and retinal, the extreme diminution of the red blood globules to nearly a tenth of the normal, the aspect of the patient, proved; that it was progressive, the man's condition, July 28, compared with his condition seven weeks before when he gave up working on the farm, is sufficient evidence. Had he not been put on arsenic when he was there is no rational ground to doubt that he would speedily have died, and then there would have been no occasion to hesitate signing the death certificate progressive pernicious idiopathic anemia, for all the textbooks would have been treated with due respect.

The only features at variance with a typical picture of so-called pernicious anemia are the emaciation, the recovery, and the absence of loud cardiac *bruits*. Emaciation is common in simple anemia; all writers except Quincke agree that it is the exception in the pernicious form. The same

is true of recovery. Quincke claims ten recoveries out of thirty-one reported cases. S. Laache<sup>1</sup> five recoveries out of eleven very characteristic and carefully recorded cases. Loomis (1884) says death occurs in ninety per cent. of all cases. Bartholow (3d edition), who is the reverse of a therapeutic nihilist, closes his few remarks on treatment thus: "Unfortunately, hitherto no results have followed the treatment and the cases have pursued their evil course until the end." Flint (5th edition) says truly: "The prognosis is affected materially by the latitude of the signification of the term pernicious in this application of it. If a fatal termination be essential for the disease to be considered pernicious, of course there is no possibility of recovery. This is an extreme view. . . . Cases have been reported presenting the requirements for the diagnosis of pernicious anemia in which recovery has taken place."

Immermann, writing for Ziemssen's Cyclopaedia in 1874, said: "I hold that no doubtful case of extreme and fatal anemia should be admitted into the present category, unless, after we have sifted every possible cause, we remain unable to account, either rationally or empirically, for the progressive course of the anemic symptoms. The term progressive pernicious anemia ought to be restricted to those cases of extreme anemia which tend uninterruptedly towards a fatal issue, notwithstanding appropriate tonic treatment, and for the malignity of whose course and termination no adequate cause can be discovered, either in the patient's circumstances or in the previous state of her constitution. The former of these characteristics is included, the latter implied, in the name assigned to the disease."

But Immermann goes even farther than this and says elsewhere: "It is clear that if the progress of our etiological knowledge should at any future time enable us to trace the development of a certain proportion of cases of malignant anemia to agencies whose operation is either rationally or empirically understood, those cases will, *ipso facto*, be withdrawn from the present category, and included among the forms of ordinary symptomatic anemia. The sole plea for retaining them in their former place would be their similarity, as regards symptoms and prognosis, to progressive pernicious anemia; on etiological grounds, it would be necessary to detach them from the group."

Still again he says: "I must again insist on the complete inefficacy of every kind of treatment, both dietetic and medicinal (all the more striking as a certain number of the recorded cases occurred among the poorer class), as a leading feature of the disease, and which distinguishes it alike from chlorosis and ordinary anemia." In still another place, speaking of prognosis, the same writer says: "But the chance of a favorable result is in the highest degree doubtful, even apart from pregnancy, when the disease is well marked. Our present experience justifies us in regarding every case as tending inevitably to a fatal issue."

A generous, easily digested diet, iron, quinine, strychnine, ergot, arsenic, intravenous injections of milk, transfusion, have been the measures most

generally and most hopefully resorted to in pernicious anemia. The stomach often refuses to digest the nourishment and rebels against iron. Ergot is only a palliative aimed at a symptom—the hemorrhages. Transfusion has been proved impotent on several occasions, though Quincke reports three recoveries out of twelve attempts. Successful results have been reported from intravenous injections of milk, but I know nothing about the details of the cases. The use of arsenic has hitherto met with not a few favorable results, and has been especially recommended by Bramwell, Warfvinge, and Laache.

I have abstained from wearying you with any elaborate differential diagnosis, as I did not conceive that it would further any more useful end than a cheap exhibition of medical pedantry. Having endeavored to report the case truthfully, it seems to me it speaks for itself. There was evidently something more than a simple anemia, and something different from chlorosis; the absence of extreme splenic enlargement, of all glandular enlargements, and of any marked change in the proportion of white corpuscles in the blood, declare against leucocythæmia, and the absence of glandular hypertrophies against pseudo-leukæmia. The oligocythæmia, or diminution of red corpuscles, was as pronounced as is often reported, and is not far removed from Hayem's extreme limit, placed at 450,000 to the cubic millimeter.

The blood of a female patient now in the hospital, who is extremely blanched from flowing for six months owing to retained placenta, still gives 2,660,000 red globules to the cubic mm.

The effects of chlorosis generally show themselves at puberty and almost exclusively in females; it is not attended by any liability to dropsy, is scarcely ever accompanied by fever or by a hemorrhagic diathesis; it is generally amenable to treatment. Leukæmia and pseudo-leukæmia are progressive and malignant, are associated with fever and hemorrhage; they are both characterized, however, by hyperplasia of the lymphatic glands and of the marrow of the bones, and the former, in addition, by great enlargement of the spleen and positive increase of the white blood corpuscles from a ratio to the red of one in several hundred to one in twenty, ten, or even one in three or four in extreme cases.

Biermer,<sup>2</sup> of Zurich, first used the term progressive pernicious anemia, to describe fifteen fatal cases which came under his notice at Zurich, between the years 1867-71; Gussersow<sup>3</sup> published, in 1871, an account of five similar cases of "extreme anemia in pregnant women," also observed at Zurich.

In pernicious anemia the number of red globules is probably invariably diminished to a striking degree, unless one is willing to admit with Quincke what he calls a "transition stage." The condition of the red globules is characterized in general, according to that observer, by extraordinary varieties in form and size, which he terms *poikilocytosis*. He found these changes well marked in twelve cases, indicated in two, absent in one. Such changes are certainly not constant, and not pathognomonic.

<sup>1</sup> Die Anämie, von S. Laache. Christchurch—1883.

<sup>2</sup> Correspondenzblatt f. Schweizer Aerzte, Jahrgang II. 1872. No. 1.  
<sup>3</sup> Archiv für Gynäkologie, Bd. II. 1871. Heft 2, s. 218.

Hayem and S. Laache agree with Quinke as to changes in the size, but not of the form, of the globules. These they found frequently increased in size. Both, but especially Laache, lay great stress upon the increase observable in the coloring matter, the hæmoglobin, of the globules. The recorded cases justify Laache in the statements that the number of globules may fall below 500,000 to the cubic mm. without death ensuing as an immediate consequence; and that the number may fall below 500,000 and still be restored to the normal without transfusion.

The latest contribution to the pathology of pernicious anæmia is that of Sasaki,<sup>1</sup> who, while carefully studying the intestines from fifty autopsies, met with those from two patients dying from this disease. In these he detected certain marked changes in Meissner's and Auerbach's ganglionic plexuses throughout the intestines.

Quinke<sup>2</sup> takes the following position in regard to the etiology of the disease: "If one considers the clinical symptoms of pernicious anæmia they, as well as its etiology, show that we have to deal with a very characteristic pathogenic condition, whose cause, however, is not a simple and single one, but that a variety of pathological processes may precede and lead up to the malady." Elsewhere he contends for a "secondary pernicious anæmia" in cases of cancer and cirrhosis of the stomach. Lépine<sup>3</sup> distinguishes three forms in regard to origin: A splenic and medullary form; gastro-intestinal; that occurring during pregnancy.

The standpoint of both of these observers is very different from that of Immermann previously quoted, who undoubtedly would reject many of the thirty-one cases reported by Quinke. Sasaki, following Lépine, regards his two cases as belonging to the gastro-intestinal variety, and draws the following conclusions, which I take from Dr. W. F. Whitney's abstract of his paper:<sup>4</sup>

(1) It is highly probable that the gastro-intestinal form of pernicious anæmia may be produced by recognizable anatomical lesions in the intestine.

(2) Pernicious anæmia can be caused by an atrophy of the intestines. The correlated change in the nervous apparatus coming under the class of parenchymatous degeneration.

(3) In the affection of the intestine which is not diffuse, and does not extend over a large area, the changes in the plexuses are restricted in a corresponding manner.

Should these two observations of Sasaki's be supported by others it seems to me that, in regard to one class of these cases, we may look upon ourselves as initiated into a little higher degree of the mystery; and instead of expressing our ignorance in terms of a mysterious change in the red blood corpuscles, we may then express it in terms of a mysterious change in the intestinal nerve plexuses.

The phrase "progressive pernicious" is mainly objectionable if it is supposed to imply a necessarily fatal termination; the term "idiopathic" ceases to be applicable as soon as we get some clear idea of the cause or causes which undoubtedly exist.

## A CASE OF MYXCEDEMA WITH ATROPHY OF THE OPTIC NERVES.<sup>5</sup>

BY O. F. WADSWORTH, M.D.

It is only quite recently that the disease known as myxœdema has excited much attention; its pathology, beyond the fact that there is a deposit of mucine in the subcutaneous tissues, is still unknown; and even the symptoms observed in the cases reported have presented in some respects considerable variations. Although symptoms pointing to disturbance of the cerebral nervous system have occurred in some cases, no affection of the eyes, in particular of the optic nerves, has, so far as I am aware, been described. It may therefore be of interest to put on record the following case, in which there was atrophy of the optic. It may well be that the optic atrophy was only coincident, and had no direct connection with the myxœdema. Yet primary atrophy, as this evidently was, when it affects both eyes, is of comparatively seldom occurrence as an independent lesion.

Mrs. C., aged forty-two, a large, strongly built woman, applied to me at the Boston City Hospital, June 27, 1884, because of failure of sight. She was in fairly comfortable circumstances, and since an attack of measles, when fourteen years of age, had never been sick. She had been married twelve or fifteen years, but never been pregnant. Her catamenia had been regular till three years ago, when they ceased.

Some seven years ago her fingers and hands, and two or three years later her feet and the lower part of her face, lips, nose, and eyelids began to increase in size. The enlargement gradually became greater, and for a long time she had been obliged to have her boots made for her, being unable to find any large enough. Her speech became somewhat thick and slow, and her movements slower than formerly. Except for an occasional feeling of numbness in the parts affected, and of burning in the feet and legs, there had been no special discomfort. Of late, however, she had experienced slight dyspnoea on active exertion. Failure of sight was first noticed a year and a half ago, and had continually progressed. Careful inquiry both of her and her husband failed to elicit any history of pains anywhere. She had never had headache. There had been no failure of intelligence or memory. Her appetite was good, bowels somewhat sluggish, micturition normal. She slept heavily.

The lower part of the face was full, heavy, of waxen hue, the natural folds obliterated; the lips full; the nose large, its alæ broad and thick; the eyelids baggy. The hands and fingers were large and square, the thickening being most pronounced on the palmar surface, where the tissues could be pinched up in thick folds and gave the feeling as of an excessive development of subcutaneous fat. The feet were very large and broad, the swelling not extending above the ankles, and, although there were large varicose veins of the right leg, there was no pitting here or elsewhere. The tongue was large and rather pale. The skin was not dry to the touch, but she stated that she never perspired. The thyroid was of normal size. Auscultation revealed

<sup>5</sup> Read before the American Ophthalmological Society.

<sup>1</sup> Virchow's Archiv, Bd. 96, s. 287.

<sup>2</sup> Deutsch. Archiv f. Klin. Med., Bd. 20, s. 24.

<sup>4</sup> Boston Med. and Surg. Journal, vol. cxi, p. 543.

nothing abnormal in heart or lungs. Temperature and pulse were normal. The patellar-tendon reflex was present. There was no anesthesia of the skin. The urine was normal in every respect.

Examination of the eyes showed the conjunctiva, cornea, and iris to be normal. Movements good. R. only perception of light. L. V. =  $\frac{2}{30}$ ; F. contracted in all directions, but to much greater degree upward and outward. Media clear. In both eyes the discs were sharply defined, gray with slight bluish tinge, without vascularity; the central vessels, both arteries and veins, small; in other respects the fundus normal.

Some weeks later the patient was admitted to the hospital, in the nervous and renal department, and remained for about a month. During this time her general condition remained the same, but the vision of the left eye varied somewhat; on September 9 it was recorded as  $\frac{2}{30}$ , but when I saw her last, at the end of September, and a fortnight after she had left the hospital, it was  $\frac{2}{30}$  -  $\frac{2}{30}$ . No farther symptoms had developed.

### CASES OF URINARY CALCULI.

BY FREDERIC HENRY GERISH, M.D.,

*Surgeon to the Maine General Hospital, Portland; Professor of Anatomy in Bowdoin College, etc.*

CASE I.<sup>1</sup> N. F., a farmer, aged seventy-five, for more than half a century a resident of Penobscot County, Maine, consulted me on the twelfth of May, 1883. He had experienced more or less uneasiness in the region of the bladder for twenty years, and, nine years before my seeing him, had an attack characterized by such difficulty in micturition that he was obliged to have his urine drawn for some weeks regularly, and at intervals afterward. For the past four years it has been necessary to resort to the catheter almost every day, and his trouble has been so much worse during the last eighteen months that he has had to abandon all labor. There is pain nearly all the time in the penis, and, at the neck of the bladder, pricking pain, which is much greater when he is sitting. Consequently, he keeps on his feet a great deal, moving slowly about with a cane in each hand, relieving himself occasionally by kneeling beside a sofa or bed, on which he rests his elbows. If the urine is allowed to accumulate for more than an hour, his suffering is aggravated. He is always more comfortable, sometimes entirely so, for a short time after evacuating the bladder; and, as the case is much greater after drawing than after passing water naturally, he commonly empties the viscera artificially. There is occasional priapism, and, during urination, the stream is liable to stop suddenly. The urine contained a large amount of phosphates and many granular casts a year ago; but a recent examination shows that there are no casts and no albumen. In the twenty-four hours selected for the test, he passed his water naturally thrice, and drew it off twenty-five times; seventy-two fluidounces was the entire result of these twenty-eight evacuations, showing that the bladder

could hold two and a half ounces without such distension as to cause agonizing pain. A year ago he began to use morphine, at first in ordinary amounts; but the dose was gradually increased, and his daily allowance now is more than five grains, usually taken in two equal parts, one in the morning, the other at night. His appetite and digestion are excellent, the pulse, respiration, and temperature normal. There is some constipation, and the thirst is considerable. His strength is failing, he is pale, haggard, emaciated, and his face indicates long-continued suffering.

The patient having been put to bed, a twenty-three French steel sound was readily introduced, and immediately touched a stone. The examination caused so much pain that it was thought best to give an anesthetic before completing the exploration. Ether was given, and a thirty sound was easily passed without enlarging the meatus. The calculus was free in the cavity. The prostate was found to be much enlarged laterally. A suppository, containing eight grains of quinine, was given, and no inconvenience resulted from the examination.

After keeping the patient under observation a week, I determined to attempt litholapaxy. Ether was administered, two ounces of water were injected, and a Bigelow lithotrite introduced without difficulty. But, though I could easily reach the stone with a metallic catheter or sound, I could not touch it with the lithotrite, though my efforts were continued for an hour and a half, and only abandoned then because of my fear that longer instrumentation would harm the patient. No unfavorable symptoms succeeded this severe trial of the patient's strength, the pulse kept below ninety, and the temperature never rose above the normal line.

After five days, lithotripsy was again essayed, Prof. S. H. Weeks, Dr. L. W. Pendleton, and Dr. I. E. Kimball kindly assisting. The result, however, was the same as before: the lithotrite was inserted with perfect ease, but its movements in the bladder seemed to be interfered with by obstacles which were not apparent when a sound was introduced, and it never touched the calculus. My colleagues had an equal lack of success, and it was decided to perform lithotomy. Accordingly I operated, adopting the lateral method. For some minutes I searched with my forefinger in the meshes of the strong bands which seemed to cross the cavity of the bladder in every direction, breaking some of them in my efforts to explore thoroughly, but I did not find the stone. On withdrawing my finger, I felt, close to the neck of the bladder, a sharp, transverse ridge, behind which I pushed the digit, which immediately entered a larger sack with smoother walls, and here the stone was found lying entirely free, and was quickly extracted with the forceps. It measured one inch and a quarter (32 mm.) in its longest diameter, and weighed one hundred and thirty-four grains (8.7 grams). It was rough, and evidently phosphatic.

The reason of the failure to reach the stone with the lithotrite was now plain: the bladder was divided into two parts by a vertical, transverse partition, the lower edge of which extended to the neck of the organ. An instrument whose beak was long

<sup>1</sup> Reported to the Maine Medical Association.

and had a sweeping curve, like a catheter, would slip behind this septum; whereas, one with a short beak and a sharp bend, like a lithotrite, must go in front of it. The sounds struck the calculus, because they were carried into the posterior chamber; the crushing instrument never came in contact with it, as it always got into the anterior compartment.

For three weeks everything progressed very favorably. The pain was so largely diminished that the amount of morphine required to control it was immediately reduced to a grain a day, and then gradually to less than half a grain. The wound partially closed, until the greater part of the urine was passed by the natural channel. But then the reparative powers refused to continue their work, the strength of the patient perceptibly diminished, and he lost ground slowly, but steadily, until the 7th of July, when he died, forty-four days after the lithotomy.

At the necropsy it was found that the walls of the bladder were immensely thickened; the lining membrane was inflamed and covered with a smear of mucus, mingled at spots with a phosphatic deposit of the consistency of soft mortar; the partition was thin, but firm, resembled mucous membrane, and divided the cavity into two unequal compartments, the anterior being the smaller, and traversed by trabeculae of (apparently) inflammatory formation.

The case is reported on account of the deformity of the bladder, which is sufficiently uncommon to deserve recording. It is possible that the failure of eminent surgeons to discover stones, whose presence has been demonstrated previously, may sometimes be accounted for by such an abnormality of structure. The result of treatment would probably have been different if the operation had been performed before the vitality of the system had been undermined by years of suffering.

CASE II.<sup>1</sup> E. H. B., a store-keeper, aged seventy-three, a resident of Portland for many years, presented himself for treatment on the 29th of June, 1883, with the following history: He has always been strong and well, an attack of erysipelas in the face being the only illness he can recall. He has been accustomed to take frequent plunges in the salt water, and I had heard that he practised sea-bathing all the year round; but this rumor he stated was incorrect, modestly saying that he had never taken a swim earlier than the 14th of April, or later than the 24th of November. He is used to hard work, and has always been a plain, temperate liver.

About six weeks before he came to me, he began to have frequent desire to urinate, and micturition became painful. The distress was altogether in the region of the bladder; there was no sudden stoppage of the stream. The urine was not abnormal. His general condition was excellent. A twenty-three French sound struck a stone immediately. At several following sessions sounds of gradually increasing size were introduced for the purpose of educating the urethra, of ascertaining the effect of instrumentation, and of dilating the passage up to the size of the lithotrite. No chill or inconvenience was ever experienced, excepting the pain incident to the passage of the instrument.

The symptoms, however, speedily grew worse: the stream of urine was frequently arrested, the desire to empty the bladder came at shorter intervals, and the pain became more severe. In twenty-four hours he passed thirty-four fluidounces of urine, evacuating the bladder eighteen times.

On the fourteenth of July, assisted by the gentlemen who were with me in the former case, I performed litholapaxy. The etherization occupied but four minutes. The Bigelow lithotrite quickly grasped the calculus, which measured an inch in diameter, and was very hard. It was crushed in a few minutes, without removal of the instrument. The fragments were washed out easily. The entire procedure occupied forty-one minutes. A suppository of quinine and morphine was given before the patient awakened from the ether-sleep; no other anodyne or antipyretic was required during the convalescence. With considerable difficulty the patient was persuaded to stay in bed about a week, although he protested he was entirely well; and, on the eleventh day, he walked a mile to his warehouse and back again without discomfort or exhaustion. A year and a half has elapsed since the operation, and there has been no sign of a recurrence of stone. The patient's health is perfect.

The fragments when dried weighed one hundred and thirty-one grains (8.5 grams). The pieces which came from the surface of the calculus were of a dark-brown color, tuberculated, and so hard that they were scarcely affected by the file; others, evidently from the inner parts, were whitish, and tolerably dense; and those of a third variety were of a light brownish hue, and friable. Dr. Edward Preble examined them chemically and microscopically, and decided that the calculus was made up of oxalate of lime, simple and triple phosphates, and urate of ammonia.

## REPORT ON SURGERY.

BY A. T. CABOT, M.D.,

*Surgeon to Out-Patients, Massachusetts General Hospital.*

### ACTION OF ERYSIPELAS UPON MAMMARY CANCER.

DR. JANCKE<sup>2</sup> and PROFESSOR NEISSER report a case in which erysipelas was inoculated upon a breast with an inoperable cancer. The organisms (micrococci) used in the inoculation were obtained from Dr. Fehleisen, who had prepared them in a pure form by cultivation upon meat-gelatine. The patient was a woman forty years of age. The tumor was of rapid growth and had recurred after two removals. A little mass of micrococci, about as large as the head of a pin, was rubbed into a small surface of skin, carefully scarified.

Within seven hours there was a violent chill, and a blush appeared which rapidly extended and was accompanied by high fever. Death occurred at the end of the fourth day.

Even in this short time a very decided change was noticed in the cancerous mass, which became smaller and softer.

The *microscopical examination* confirmed the

<sup>1</sup> Reported to the Practitioners' Club, Portland.

<sup>2</sup> Central bl. f. Chir., June 21, 1881.

diagnosis of carcinoma. The tissues were filled with masses of micrococci, which could be seen extending into the cancer alveoli, from many of which the cells had disappeared. The exact changes which the epithelial cells underwent could not be exactly made out, although they could be seen to be paler with less distinct markings.

The result of this examination, then, was that the micrococci excited a destructive influence upon the carcinoma, causing a disappearance of the epithelial cells from their alveoli.

PROFESSOR NEELSEN<sup>1</sup> reports his observation of a case of mammary cancer which suffered from two attacks of erysipelas, and in which the microscopical appearances were in a degree contradictory of the inferences drawn from the above case of Professor Neisser.

The patient, a woman forty-one years of age, presented herself with cancerous tumors in both breasts. The glands in the left axilla were likewise affected. The left breast was removed, together with the contents of the axilla.

On the thirtieth day the wound, which had contracted to a small granulating surface, was attacked with erysipelas which spread over the right breast, and was followed by a diminution of the size of the tumor on that side. A slight gangrene of the skin occurred over this tumor, and was followed by an abscess behind it, which was incised.

Three weeks after the subsidence of the first attack of erysipelas a second followed, starting in this instance over the right breast. This proved fatal at the end of fourteen days.

A microscopical examination of the tumor on the right side, over which two attacks of erysipelas had run, showed the following appearances:—

In limited portions the ordinary alveolar structure and cellular character of the cancer were preserved. In by far the greater part of the tumor, however, the contents of the alveoli had undergone fatty degeneration (necrosis).

The connective tissue around the alveoli was filled with small cells. A portion of these were evidently leucocytes, but the larger part of them were young epithelial cells which were forcing themselves in every direction into the surrounding tissues, even reaching and infiltrating the overlying skin.

Both observations seem to show, therefore, that erysipelas may bring about a destruction of existing carcinoma, while, according to Neelsen, a second effect may be the stimulation of younger portions of the cancer to increased growth.

#### FORMS OF INTESTINAL OBSTRUCTION THAT MAY FOLLOW HERNIA AFTER REDUCTION.

Mrs. TRIAL<sup>2</sup> calls attention to the following conditions which may lead to obstruction of the intestine subsequently to the reduction of a strangulated hernia.

1. Organic stricture of the intestine may follow as a result of constriction in the hernial sac.

The lesion in this case may be either a loss of substance in the mucous membrane, and a consequent cicatricial contraction. Or a well-localized

peritonitis may be followed by shrinking of the inflammatory products thrown out, and a narrowing of the bowel may ensue.

In either case the symptoms of obstruction generally appear in from six weeks to two months, although they have been known to delay their appearance until the end of eight months.

2. The herniated loop after reduction may become fixed to the abdominal parietes by adhesions.

This condition acts in two ways to bring about obstruction. The bend or kink caused by the attachment of a loop of the intestine to the abdominal wall renders the passage of the intestinal contents difficult, and the necessary friction and stagnation at that part is liable to set up ulcerative processes which act secondarily to increase the obstruction.

M. Treves in this connection mentions a case in which serious obstructive symptoms followed slowly upon the reduction of an inflamed femoral hernia. He opened the abdomen, found the intestine adherent about the ring, separated the adhesions and obtained a good recovery for his patient.

3. The two ends of the loop may be fixed together by adhesions.

This condition is only possible in the small intestine. Occasionally the two sides of the loop may adhere together and be fastened side by side like the barrels of a double-barrelled gun.

4. Adhesions between the reduced loop and the parietes may develop into a band, behind which an internal strangulation may subsequently occur.

5. To the inflamed peritoneum about the hernial orifice a part of the omentum may become adherent and thus lead to internal strangulation.

#### CANCER OF THE RECTUM.

In the surgical section of the recent International Medical Congress held at Copenhagen, a long discussion<sup>3</sup> was had in regard to the treatment of rectal carcinoma.

*Esmarch* opened by recommending early and thorough extirpation of the disease with the knife, and said that the prognosis was by no means hopelessly bad. Recurrence is less common in cases of cylinder-celled cancer affecting only the superficial layers of the mucous membrane than in alveolar cancer of the deeper tissues. Small movable nodules may be excised from the wall of the bowel, but in case of more extensive disease the removal of the whole rectum to a point above the portion affected is necessary. This extirpation may be properly carried even into the sigmoid flexure.

If the external sphincter is not removed the incontinence which is left is not complete, and the resulting condition of things is much less distressing than that which would be caused by the cancer if left alone.

*Bogart* advised lumbar colotomy for these cases, and also for other non-malignant strictures and for severe ulcerations of the rectum. To have a favorable effect the colotomy should be done early.

*Vernail* said that he had tried both extirpation and lumbar colotomy in the treatment of rectal carcinoma, but that he had now adopted the median linear resection as the most advantageous operation

<sup>1</sup> Central bl. f. Chir., November 1st, 1881.

<sup>2</sup> Lancet, June 7th, 1881.

<sup>3</sup> Central bl. f. Chir., October 18th, 1881.

for these cases. With the thermo cautery he pierces a hole from the outside to a point above the stricture. Through this he introduces a probe, and then with the cautery he severs the bridge of tissue between this and the anus.

*Trelat* also spoke in favor of rectotomy, with colotomy to fall back upon in exceptional cases of pain, hemorrhage, or stenosis.

*Volkman* advocated extirpation, which, he said, effected a permanent cure in a certain proportion of cases. He had himself in one case obtained a cure of ten years' duration.

The prognosis after the operation he regarded as good, when the peritoneum is not opened, and when this accident does happen, as no worse than after colotomy. In successful cases the condition of the patient after extirpation is much more bearable than after the establishment of an artificial anus.

He operates only in cases in which, with the aid of anæsthesia, he can reach the upper edge of the disease, and in which the mobility is such as to exclude implication of the bladder.

In difficult cases he makes an incision along the raphe, anteriorly as well as posteriorly, in order to afford more room. If the peritoneum is opened he sews up small rents and drains large ones. When colotomy is necessary, he does it anteriorly rather than posteriorly.

*Küster* said that he had seen very few cases in which colotomy was indicated. In cases not proper for extirpation a thorough scraping of the disease and subsequent cauterization obtains for the patient a condition of comparative comfort for weeks or even months.

The stomach was contracted in all its diameters. Externally, the course of its vessels was marked by dull red lines a quarter of an inch wide. The entire mucous membrane presented the caustic effects of the acid in full degree. It was of a dull white color, with here and there a faint pinkish tinge in the depressions of the rugæ, which were remarkably developed. The entire inner aspect of the organ had an appearance as if it had been suspended a moment in a thin mixture of plaster of Paris which, hardening, had coated the mucous lining of the stomach with a dense white deposit, hard and rough to the touch and easily cracked.

For about six inches below the pylorus, the mucous coat of the duodenum showed limited areas of the whitened and thickened appearance seen in the stomach, but less in extent and degree; it was chiefly manifested upon the summits of the mucous folds, the intervening depressions having escaped the caustic action. The caustic and irritant effects diminished rapidly as one proceeded downward, and in the lower part of the duodenum and upper part of the jejunum showed only in a moderate redness of the mucous membrane.

The liver, spleen, and kidneys were deeply reddened and were injected. The bladder contained four ounces of urine of normal appearance.

Dr. JOHN HOMANS stated that he had known death to occur inside of ten minutes without foaming at the mouth, in a person who had taken a teaspoonful of clear carbolic acid liquefied.

#### RAPID COURSE OF SYPHILIS.

Dr. J. J. PUTNAM reported a case of syphilis in which a series of lesions (ulcerated tonsils, iritis, symmetrical gummatous tumors on the arms, papular eruptions) had come on within a few weeks after a sore on the foreskin which had been followed by non-suppurating lumbos.

It could not, to be sure, be affirmed with certainty that the symptoms were not due to a previous infection. There had been exposure previously, but no history of infection could be obtained.

Dr. F. B. GREENOUGH thought that there could hardly be a question but that there must have been earlier infection. Even secondary symptoms are rare in so short a time, and while the case is interesting we ought not to accept gummata as the result of infection at this time, unless an earlier infection can be disproved.

Dr. PUTNAM referred to cases reported by Mauriac, in which there were cerebral symptoms at an early date, which were supposed by Mauriac to depend on gummata.

Dr. J. C. WHITE asked if there had been any indications of the existence of cutaneous gummatous infiltration? He remarked that it would be unwarranted to infer the presence of gummata within the cranial cavity from the mere occurrence of undefined cerebral symptoms.

Dr. GREENOUGH said that while early cerebral symptoms have many times occurred, yet he agreed with Dr. White that it is absolutely impossible that gummata have existed within a few weeks, or even a very few months, of infection.

Dr. JOHN HOMANS said that a patient of his had

## Reports of Societies.

### BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

C. M. BUCKINGHAM, M.D., SECRETARY.

DECEMBER 22d, 1881. The President, Dr. CHARLES D. HOMANS in the chair.

#### A CASE OF CARBOLIC ACID POISONING.

Dr. F. W. DRAPER exhibited the stomach of a young woman who, with suicidal intent, swallowed an ounce of undiluted carbolic acid. It was impossible to obtain accurate information concerning the symptoms or their duration, as the girl was alone when she took the dose, and attention was first called to her condition by her moans. She was found unconscious, cold, sweating freely, frothing at the mouth. Her lips were blanched by the local action of the acid. There was no vomiting. The poison was taken upon an empty stomach.

At the autopsy, eight and a half hours after the death, a remarkable lifelike flush of the cheeks and brightness of the cornea were observed. The mucous membrane of the mouth and lips was bleached. On section of the body the odor of carbolic acid, though decided in its manifestation, was not extraordinary. There was nothing remarkable about the heart, the blood, or the lungs. The œsophagus was uniformly whitened throughout its

died within eight months of the initial lesion, and at the post mortem the cerebral vessels were found occluded by gummata.

"PERNICIOUS" ANÆMIA, WITH RECOVERY.<sup>1</sup>

DR. G. B. SHATTUCK read a paper including the report of a case.

DR. FRANCIS MINOT alluded to three cases of pernicious anæmia which had come under his observation, and which presented the usual symptoms of failure of strength, dyspnea on exertion, and systolic cardiac and carotid murmurs. In one of these cases very marked improvement followed immediately the employment of arsenic, and continued for eight months. The symptoms then returned in spite of the continuance of the remedy.

DR. F. W. DRYER said that he recalled very distinctly the condition of the patient who was the subject of Dr. Shattuck's paper. It was strikingly characteristic of an extreme degree of anæmia, to which it was evident that the man was about to succumb. So reduced was he in his strength, and so hopeless in his mental state, that the suggestion of a change of treatment to wine and Fowler's solution was made without any expectation that he would live long enough to derive any possible benefit from it, it being regarded as a probably fruitless last chance. There was no doubt that the anæmia in this case was rightly characterized as of the "pernicious" and "progressive" type, the significant addition to the title of the paper of the words "with recovery" being the most interesting part of it. For while the fact must be evident to any one who studies the literature of idiopathic anæmia that medical authorities are very far from unanimity concerning the nature and pathogeny of the disease, all agree with regard to its gravity, and most practitioners would accept Immermann's statement that "the absolute fruitlessness of all tonic treatment, and the uninterrupted progress of the disease toward death are the essential characteristics of this peculiar and enigmatical affection."

With regard to the source of the usefulness of arsenic in this disease, we are almost as much in the dark as we are as to the cause of the condition which it sometimes relieves. It adds little to our knowledge to call arsenic an "alterative"—a "modifier of nutrition," as Wood defines it. The recent theory, quoted by Dr. Shattuck, that the seat of the affection (pernicious anæmia) is in the intestines instead of the blood, obtains some support from the fact that arsenic is the remedy which clinical experience has found to be most useful in staying the progress of the disease; for it is well known that, in certain varieties of chronic diarrhoea, Fowler's solution has been found curative when other agents have failed.

DR. R. T. EDS recalled the case of a man reported by him some years ago<sup>2</sup> who suffered from weakness, headache, dyspnea, and loss of appetite. He was extremely pale. There was a slight cough and cardiac souffles. The spleen was slightly enlarged. The urine contained a trace of albumen, a few casts, a little pus and blood.

Several blood counts ten days after his enter-

ing the hospital gave an average of 780,000 red corpuscles to the cubic millimeter. The treatment consisted in rectal feeding for a few days and the use of Fowler's solution, the latter having been already given for three days when the first count was made. Seven days after the first count another gave 735,000; but in four days more it had risen to 955,000, and in another week to 1,290,000. Seventeen days later it was 2,295,000. A few days later he left the hospital and remained well so long as we could keep trace of him.

In by far the greater number of cases which have recovered from idiopathic anæmia the treatment has been arsenical. There are enough exceptions, however, to this rule to show that arsenic cannot be looked upon exactly as a specific.

DR. GEORGE B. SHATTUCK said that he did not mean to make any claim for specific virtues for arsenic. Sometimes it could not be borne at all, sometimes it failed entirely to bring relief, sometimes improvement occurred independently of its administration, as shown by Laache's admirably reported cases. A number of cases, however, were on record in which it might fairly be claimed to have cured the disease and saved the patient. He did not think it possible to make a satisfactory diagnosis of pernicious anæmia without the ophthalmoscope and the hamacytometer.

The nomenclature was undoubtedly faulty, but with the existing state of ignorance it would be hard to improve it. In any case the statements in the textbooks should be revised.

DR. F. H. WILLIAMS said that the discussion has an interesting bearing on the therapeutic action of iron. Arsenic and iron have much the same symptoms in cases of poisoning, they kill in the same way. If then anæmia is relieved by arsenic better than by iron, these facts together tend to show that iron does not, as has been supposed, furnish a food to the blood, in which case it should be superior to arsenic.

DR. JOHN HOMANS read a paper on EXPLORATORY ABDOMINAL INCISIONS.<sup>3</sup>

DR. GEORGE W. GAY asked the reader if he had abandoned tapping.

DR. HOMANS answered that he had in almost every case. If he had to do with a large doubtful tumor, he might tap, but not otherwise.

DR. GAY said that a few years ago he had been greatly surprised at the strong ground then taken by Dr. Homans in this matter, but that he was more and more coming to the same view. He mentioned a patient tapped not long ago, Dr. Cheever seeing the patient with him. Some leaking followed, and then peritonitis. Ovariectomy came later and the patient died. He thinks the tapping was unfortunate, at the same time it was justifiable because when he tapped the tumor could not be made out.

On the other hand he had seen very fortunate results from tapping. In September of 1879 he examined a hospital patient under ether with Dr. Filled, and tapped, withdrawing two or three pailfuls of fluid, and then found a large polycystic tumor. A probe entered the uterus five or six inches. The woman left the hospital and afterward became his private patient. She was tapped

<sup>1</sup> See pages 2-5 of this number of the Journal.

<sup>2</sup> Boston Med. and Surg. Journal. October 31, 1880.

<sup>3</sup> To be published in the Journal of January 8.

every ten, twelve, or fourteen days, getting two or three pailfuls of ascitic fluid at a time, and this was done to his knowledge, though not always by himself, as many as ninety times. It is now two years since she has been tapped, the interval between the last two tapplings being three months. Before the last tapping the uterus was eight or nine inches deep. Since the last tapping she has been in fair health.

The speaker mentioned a bullet being removed from the omentum by Dr. Bull, of New York, some weeks since. His own tendency is toward free incisions. He felt indebted to Dr. Homans for the report of his cases, and intends to act on it.

Dr. J. W. ELLIOT said he was very much interested by Dr. Homans's paper; that within a few months he, Dr. Elliot, had made an exploratory incision in a case sent to him by Dr. Dunne, of Athol, which he thought worth reporting. The patient, aged 30, had been married three years. Five years ago she had measles. Since which time her menstruation had been irregular and sixteen months ago it ceased altogether. Three or four months later she noticed a tumor the size of a cocoanut in the lower abdomen and supposed she was pregnant. Six months after the cessation of menstruation she had a very severe pain in the abdomen accompanied by tenderness and some flowing. This attack was naturally supposed to be a threatened miscarriage. At the time of her expected confinement the tumor was about the size of a uterus at full term, but no confinement followed. Three months before he saw her she had an attack of peritonitis. Since that time she had been in bed with a temperature from  $101^{\circ}$  to  $102^{\circ}$  F. When she entered the Free Hospital for Women she was much reduced in flesh and strength. There was a large semi-solid abdominal tumor. Her temperature was  $101^{\circ}$  F.

Dr. Dunne, her attending physician, thought it was a case of extrauterine pregnancy. Dr. Elliot thought it might be a suppurating cyst or an abscess. She was evidently in a bad way unless something could be done to relieve her. They thought that tapping would be dangerous without offering a chance of cure, and therefore determined to make an exploratory incision. On opening the abdomen a sarcoma of the left ovary was found with extensive peritonitis. The tumor was so widely adherent that the wound was closed without attempting to remove it. The patient sank, and died in a few days. At the autopsy the wound was found to have united by first intention. The tumor weighed sixteen pounds. Dr. W. F. Whitney reported that "microscopic examination showed that it was essentially a round-celled sarcoma, in which large cysts had developed." Sarcoma of the ovary is, of course, a very rare disease.

Dr. H. I. BOWDREN said that the subject of opening the abdomen was until quite recently in the same condition that opening the thorax was thirty or forty years ago. He had partly prepared a paper on the bad treatment involved in letting cases go on to a painful death that might be helped by operation. In a case that had died of impacted gall-stone, with the diagnosis made, why should not the stone have been removed and the gall-duct sewed up?

He mentioned a case of Dr. Adams's: A child under two years with peritonitis and a large abdomen containing pus, was relieved by tapping although nearly moribund. Growing worse again, and the pus containing micrococci, Dr. Adams, aided by Dr. Marcy,<sup>1</sup> had opened the abdomen and washed it out with carbolic acid (1:200), and the child recovered.

He asked the reader if he thought the use of the spray necessary.

Dr. HOMANS answered that he does not think the spray absolutely needed, though he always uses it, even in tapping. It is not troublesome, and it is a part of the general surgical neatness. Its use keeps one up to the mark, and if he were to lose a patient, not having used it, he should feel uncomfortably. He feels safer with it, but the majority of ovariologists do not use it, and it is not absolutely necessary provided all other precautions are taken.

## NEW YORK COUNTY MEDICAL ASSOCIATION.

### DISCUSSION ON CHOLERA.

At a meeting of the Association held December 16th, there was a discussion on cholera, which was opened by Dr. E. G. JANEWAY. There could scarcely be a doubt, he said, in the outset that the disease was of specific origin, and having its home in India; although there were still a few writers who seemed to think that it might arise spontaneously under conditions favorable to its development. The claims of Koch for a specific microbe for cholera had been admirably stated by Dr. Flint in his recent paper before the Association; but since then certain points had been determined which rendered Koch's position stronger than before. Thus, at the time when Dr. Flint read his paper, it was claimed by Mr. Timothy Lewis, that comma-like bacilli identical in size, form, and in their reaction with aniline dyes, with those found in choleraic dejecta were ordinarily present in the mouth and fauces of perfectly healthy individuals; but Koch had now shown that this form of bacillus had been known for some years, that it differed from the comma-bacillus in being longer, more slender, and not so blunt at the ends, and, finally, that it could not be cultivated in the weak alkaline peptone-gelatin in which alone the latter would develop. Again, it was claimed by Finkler and Prior, that certain bacilli found in connection with cholera-morbus were identical with the comma-bacillus of Koch; but the latter had now shown that the so-called bacillus of cholera-morbus was very different from the comma-bacillus of cholera in its form and mode of growth. Furthermore, Koch had not at that time been able to succeed in inoculating animals with cholera by means of comma-bacilli. The successful experiments of Rietsch and Nienti in this connection had, however, just been published, and Koch had now announced that he had repeated their experiments with complete success. He had, moreover, produced inoculation by using the fresh bacillus-culture in so diluted a form that not more than one hundredth part of a drop was contained in the matter injected into the duodenum.

<sup>1</sup> Boston Med. and Surg. Journal, November 20, 1884.

The animals died in from a half to three days, and after death the intestinal fluids abounded in numbers of comma-bacilli. These later proofs in support of Koch's theory seemed, therefore, to furnish the "missing link" in its positive demonstration.

Dr. Janeway then took up *seriatim* the sixteen questions which were presented for discussion at the cholera conference at Berlin, July last; which he thought would serve as useful topics for discussion on the present occasion. In speaking on the point, "Is a direct transmission possible, or must the infectious matter pass through a kind of maturity, or change of generation, in the soil or elsewhere?" he said that it looked in many cases as if there was direct transmission. It was true that the chief of Vulpian's laboratory in Paris, as reported by the journals, had recently swallowed without serious consequences some of the excreta of a cholera patient made up into pill form; but this simply showed that individually he was apparently not susceptible to the infection of cholera at that particular time. The seventh point was, "Is the infectious matter contained in the dejecta, or eventually in the vomit, or is it also to be found in the blood, urine, sweat, or air for breathing?" Dr. Janeway believed that, as a rule, the dejecta alone contained the infecting agent. The vomit rarely contained it; but, in order to be on the safe side, he thought it was better to disinfect both the vomit and the dejecta. In regard to the tenth point, "Can the infectious matter reach the body by other channels than through the digestive canal?" he remarked that this was a difficult matter to determine. Although it might not be carried to the lungs by means of the breath, it seemed possible that it might be taken into the mouth through this agency, and then swallowed. He felt confident that he had seen instances in which typhoid fever was in all probability contracted by the infectious matter being carried by means of the breath into the mouth, where it was swallowed. The eleventh point was, "Are special individual dispositions necessary to make it effective?" Such dispositions seemed to be required, he said, in all infectious diseases; but this feature seemed more marked as regards cholera than any of the others. The liability of the same individual to contract such diseases varied very greatly at different times, and he illustrated this by a reference to the cases of two resident physicians at the Riverside Hospital on Blackwell's Island. One of them, after serving there for a number of years, during which he attended hundreds of patients suffering from typhus fever, often of a very malignant type, finally contracted the disease from a mild group of cases, and himself fell a victim to it. The other, after having for years been exposed to the risk of small-pox, typhus fever, and other infectious diseases, but without taking any of them, went to Europe for a year, and almost immediately on his return to the hospital contracted typhoid fever. The sixteenth question, "Can the proof of the presence or absence of comma-bacilli be diagnostically turned to account?" he thought in the present state of our knowledge should certainly be answered in the affirmative.

In speaking of the measures that ought to be taken to protect New York from cholera, he ad-

vised that a judicious quarantine should be maintained for all vessels coming from infected ports, and claimed that, while such quarantine had not always proved successful in the past, this did not prove that it might not be so now. Then passing on to speak of certain measures which ought to be taken in order to place the city in the best possible condition for resisting its ravages in case the disease should make its appearance, he mentioned the large number of privy vaults which still remained unconnected with the sewers. The substitution of trough closets for all these was greatly to be desired; but as this was perhaps too much to expect, the vaults should, at all events, be thoroughly cleansed and disinfected. Another important practical measure that should be promptly attended to was the dredging of the slips along the river-front, many of which are now in a very foul condition, and the carrying of the sewers to the ends of the piers. In addition the Board of Health ought to watch with great care every suspicious case of disease occurring in the city, and he thought it would be an excellent plan for it to establish several convenient reception wards in different districts, in anticipation of the coming of cholera. The authorities have recently made an appropriation of \$50,000 to be used by the board in case the disease actually made its appearance, but not otherwise; but he thought it would be much better to devote a certain portion of this sum in advance to the purposes mentioned.

The number of deaths was greater during the first epidemic of cholera that visited New York (in 1832), Dr. Janeway continued, than during the last, which occurred in 1866; notwithstanding the very much smaller population of the city at that time. The number of deaths from the disease in 1866 was 1137; but if the proportion of deaths to the population had been as great as it was in 1832, there would have been 12,588 deaths. If it had been as great as in the epidemic of 1849, there would have been 7,113 deaths, and if as great as in that of 1854, there would have been 3,005 deaths in 1866. It was a remarkable fact that in the latter year fully one half of all the cases of death occurred in the institutions on Blackwell's, Ward's, and Randall's Islands in the East River; which seemed to establish the fact that the measures at that time adopted by the health authorities were efficient in controlling the disease and saving the city from a severe epidemic.

Koch had maintained that it was sufficient to ventilate a house in which a case of cholera had occurred, and advised that the premises should be vacated for six days. This, however, would often prove difficult to accomplish, and Dr. Janeway thought it would be safer to first fumigate a house, and then ventilate it. If it was simply ordered to be ventilated there would be a great risk of its not being done thoroughly; but if it was first fumigated by means of burning sulphur, there would be little doubt but that it would afterward be well ventilated by the occupants. Having referred to the various agents which Koch had found to prevent the growth of the comma-bacillus, he remarked that it was a question not yet settled whether they actually killed the microbe or not. The matter of cholera-morbus was one of some

importance, on account of the resemblance of the symptoms of the disease to those of Asiatic cholera. Under ordinary circumstances the latter diagnosis was excluded because of the absence of cholera from the country or city; but at times when the appearance of cholera was likely to be expected, the question of diagnosis was more difficult. If there was any doubt, it was far better to treat the case precisely as if it were one of Asiatic cholera. In making out the positive existence of comma-bacilli clear cultures were required, and Koch thought that every city health-board ought to have some one connected with it who was capable of making the cultures.

In speaking of the treatment, he referred to the injection of a saline solution in large quantities under the skin, as proposed by Senator; the idea being to furnish to the system a supply of salts and liquid to make up for that drained from it by the disease. The former practice of injecting such solutions into the veins, however, has never been attended with much success.

The President, DR. DETMOLD, made a few remarks, in which he expressed the opinion that the question of the essential agency of the comma-bacillus in the production of cholera was not yet decided. There were fashions in medicine as well as in other things, and at the present time it was the fashion to consider many diseases to be of parasitic origin. Whether these doctrines would stand the test of time remained to be proved.

DR. AUSTIN FLINT, SR., having remarked that he had seen something of the disease in all the epidemics that had occurred in this country, and that his experience with it had been especially large in that of 1849, said that he had formerly thought the proof was complete that cholera was not a communicable disease. To show what his views were in 1849, when he was practising in Buffalo, and where he attended 150 cases, he quoted from an elaborate article which he had prepared at that time for the *Buffalo Medical Journal* (of which he was the editor), and which was founded upon the tabulated records of nearly one hundred cases made at the bedside. The opinion expressed in this article he now believed to be incorrect, and he said that if it could be shown that in the cases of abdominal disturbance, often of a mild character, which are always so abundant during the time that cholera was prevalent, the characteristic bacillus of that disease was present, it would go far toward satisfactorily explaining the spread of cholera. Having stated that in regard to many of the questions referred to by Dr. Janeway he was not prepared to give a positive opinion, he said that he would only call attention to one or two practical points. The most successful treatment of cholera consisted in controlling the premonitory symptoms, and this was a matter upon which he said he had laid special stress in the article referred to, from which he again quoted. The portion quoted ended as follows: "It follows that the disease may with great certainty be averted in the vast majority of cases, if premonitory symptoms precede its development, and we know the latter to be the general law of the disease, although not without exceptions. Hence, a person resolved not to neglect the earliest prodromic symp-

oms, but to resort to appropriate measures of prevention, need not entertain much apprehension of an attack of epidemic cholera." In this connection Dr. Flint spoke of the great importance of having thorough house-to-house visitations made in cholera times. If every family could be visited every day by a sanitary inspector, and have the inquiry put to it whether any of its members were affected with diarrhoea, he believed the disease would undoubtedly be divested of a large share of its fatality.

The discussion was also continued by Drs. Purple and Dwyer. The former gave some account of the epidemic of 1849 in New York, when, although the first case of the disease was brought to quarantine in the beginning of December, 1848, and although occasional cases occurred after that at the quarantine buildings on Staten Island and at the institutions on the islands in the East River during the following months, nothing whatever was done by the health authorities to put the city in an efficient sanitary condition. The first cases in the city occurred in the region of the Five Points, which was not at that time provided with any sewerage, in the early part of May, and during the year 1849 there were not less than 5,000 deaths from the disease. The fact that cholera was allowed to exist in the vicinity of New York for so long a period without any attempt being made to clean and purify the city was, no doubt, the reason why it was visited with such a severe epidemic, and he thought that the lessons to be gathered from this outbreak of the disease should not be lost upon the community at the present time.

DR. DWYER spoke particularly of the epidemic at the Emigrant's Hospital on Ward's Island, in 1866. He treated some 500 cases, with about 150 deaths, and in twenty-five autopsies which he made he was struck with the fact that the gall-bladder was always nearly full of bile. Dr. Janeway had spoken of the period of incubation being from two to five days; but on Ward's Island, where the outbreak was clearly traceable to a female nurse, who came there from quarantine, the first case was taken within twelve hours after her arrival, and the second (an infant) within twenty-four hours. In the case of two pregnant women who died of cholera, on one of whom cesarian section was performed immediately after death, both the children were found to be dead.

In concluding the discussion, Dr. Janeway said that the premonitory diarrhoea was probably due to the irritation caused by the bacilli. In regard to the distended condition of the gall-bladder, noticed by Dr. Dwyer in his cases, he thought that the explanation of the fact was, perhaps, that in consequence of the drain of liquids from the system by the disease the bile became so thick and inspissated that it would not flow out freely. Dr. Janeway then presented three

#### SPECIMENS SHOWING THE INTESTINAL LESIONS OF PERIODIC FEVER.

in two of which the lesions were very slight, while in the third they were very extensive; and made some remarks on their significance, and the difficulty of diagnosis sometimes met with in typhoid.

# CLINICAL SOCIETY OF THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL.<sup>1</sup>

Dr. S. J. McNUTT had used equal parts of carbolic acid and glycerine as a local application; a zone about two inches in width was painted around the periphery of the inflammation, but in half a dozen cases under observation she had not noticed that any particular advantage was gained by the procedure. She used the tincture of the chloride of iron internally.

Dr. F. B. CARPENTER considered acetonite abortive in the sthenic variety, citing a case of erysipelas which had recurred three times. The first two attacks, under the local application of the lead and opium wash, with the tincture of the chloride of iron internally, ran their courses in ten days; the third, although it began just as the others had, was treated with the acetonite and recovered in four days.

Dr. A. F. BRECHLER said that he considered that the experiments demonstrating a special coccus for the disease as conclusive, adding that not only the inoculation with the culture of the third generation produces the disease, but also the transported culture from a distant neighborhood produced it just as certainly, and in this case it had the peculiarities of the disease as it existed in its native place. The cocci were always found in the lymphatics, and extending not with the current of the lymph but against it. After inoculation the period of incubation is from fifteen to sixteen hours.

Dr. J. H. HAWLEY had noticed that when erysipelas was present in the hospital with which he was connected, it was present, as a rule, in the other hospitals, and in other parts of the city. A more or less epidemic influence seemed to control its development. He used the lead and opium wash hot, cold, or in poultices, whichever was most agreeable to the patient. When tension existed he made early and free incisions. He had also used the injections of carbolic acid around the border of the blush, but it seemed impossible to decide what this procedure accomplished where the course of the disease was so erratic. He thought that the Lister dressing was useful to prevent infection, and had used it with good result in a case of compound, comminuted fracture of the scapula from a bullet wound, applying it all about the wounded side. Shortly after the temperature rose to 103° F., and an erysipelas developed in the arm of the wounded side, which ran its course without involving the wound under the dressing.

Dr. H. G. LATHY had used iodoform 5i to collodion 5i as an external application with apparently good success. In erysipelas of the scalp in children he had made use of the white lead, which undoubtedly reduced the irritation and scratching, while the spreading of the inflammation was checked.

Dr. C. L. STURGES in his practice in Turkey had met with many cases of idiopathic erysipelas, a theme in character and resembling typhoid fever, so common in Oriental cities, though having a more favorable prognosis and a shorter natural history. In the idiopathic cases he had learned to rely mainly on proper nourishment, stimulation, and

good nursing, using local applications as palliatives, but with no expectation of cutting short the disease.

Dr. C. H. BROWN used Trousseau's mixture as a local application, and thought that when the part was freely painted with it that it limited the disease and relieved the pain. He considered it might be of neurotic origin occasionally. He had seen a blister applied for pleurisy take on an erysipelatous inflammation with rapid improvement of the pleuritic symptoms, and he referred to the fact that a proposition had been made to inoculate with the erysipelas virus for the sake of the absorption of such effusions.

Dr. S. M. ROBERTS formerly used equal parts of carbolic and spirits of turpentine, and had thought that it limited the disease, but he now obtained as good results without it. When hyperpyrexia becomes dangerous he uses quinine if the stomach can digest it.

Dr. JOHN H. NESBITT said that he had used the nitrate of silver pencil applied to the tissues at the border of the inflamed surface, had painted the edges with tincture of iodine and with tincture of iron, in many cases without any appreciable benefit in limiting the spread of the disease. In cases of idiopathic facial erysipelas occurring in dispensary practice no internal treatment whatever was used, but he depended entirely on local applications, selecting that which seems to be the most soothing to the patient. He preferred the lead and opium wash in most cases. Some time ago he had been in the habit of sewing all scalp wounds carefully with catgut, but had frequently found it necessary to cut the stitches within two days to relieve the pain incident to tension the erysipelatous inflammation. During the past year he had washed all these wounds with a solution of the bichloride of mercury, and then applied iodoform, cotton, and a bandage. Under this treatment there has been no inflammation, while in many cases the wound has united by first intention.

Dr. JUSTIN HAROLD said that while serving as house physician and surgeon of St. Vincent's Hospital he had under observation a large number of cases, it being for a time epidemic in the wards. On the fourth of October, 1883, a case of inguinal hernia was operated upon, and the next day facial erysipelas developed, which also spread to the wound. Under energetic treatment this patient recovered, but was the starting point of all the other cases that rapidly followed. In a few days a number of compound fractures (twenty-six) began to show signs of the disease. The character of the disease was low and diffuse, which made the treatment difficult. One or two died within two weeks, while one other lived five or six months, and then died of exhaustion. All were inmates of lodging-houses before their admission to the hospital, were ill-nourished, intemperate, and in bad general health. Several other cases presented themselves at the out-patient department about this time, and these may have produced further infection, while several more were treated in the ambulance, thereby infecting the surgeon who was obliged to dress all cases of minor surgery. Even one of the first cases in the new wing contracted the disease. The epidemic became so alarming that all surgical operations were suspended for a time. The doctor

<sup>1</sup> Contributed from page 643, vol. ext.

himself contracted a facial erysipelas. The epidemic was only controlled by a thorough disinfection of all the contaminated wards by means of sulphur fumes. Whenever the temperature of a patient rose to 103° F. or over, others with simple lacerated and contused wounds would have a rise of temperature, and have other constitutional symptoms of erysipelas, but no local signs. In none of these cases was the dressing antiseptic in a strict sense. The treatment was both constitutional and local; cachectic conditions were corrected, when present, by suitable measures; light nutritious nourishment was ordered in every case. Stimulants when indicated were allowed in quantities not exceeding thirty-six ounces in the twenty-four hours. For high temperature quinine, and to overcome the irritability of the stomach the official solution of morphia; if vomiting occurred a hot poultice of mustard was placed over the abdomen, affording instant relief in the majority of cases; if delirium occurred, as it did usually, it was treated with bromide of potassium and chloral with marked relief. The tincture of the chloride of iron was of invaluable service in simple facial erysipelas, but in the other forms it did more harm than good, invariably inducing disturbances of digestion. Locally the lead and opium wash was not of as much service as the one to forty solution of carbolic acid, while a wash prepared freshly from the powdered opium did better than either, when applied hot. Solution of nitrate silver 5ss or 5i-5j of distilled water stopped the spread of the disease in every case, and was a very valuable remedy.

#### RHODE ISLAND MEDICAL SOCIETY.

A QUARTERLY meeting was held in Providence, December 18th, 1884. The President, Dr. O. C. WIGGIN, in the chair.

The subject of a museum for the promotion of anatomical and pathological studies was again brought to the attention of the society, and it was voted that a committee of five with full powers be appointed by the President to serve as a committee on the Society's Museum. The President named Drs. W. J. McCaw, G. T. Swarts, F. B. Fuller, C. M. Godding, and B. R. Symonds, as the committee.

Delegates to State Medical Societies for 1885 were announced as follows: Maine, Drs. A. D. Weeks and W. H. Traver; New Hampshire, Drs. C. D. Wiggins and Eugene Kingman; Vermont, Drs. E. M. Snow and W. R. White; Massachusetts, Drs. C. W. Parsons and E. T. Caswell; Connecticut, Drs. W. F. Hutchinson and W. H. Palmer; New York, Drs. L. F. C. Garvin and H. E. Turner.

Dr. JAMES H. ELDRIDGE read the quarterly report of the Board of Censors, recommending for fellowship Drs. Elmer S. Fiske, of Olneyville; Edward W. Penny, of Wausauk; Mary P. Root, of Providence, and Thomas J. Smith, of Valley Falls. They were unanimously admitted.

In accordance with notice given at a previous meeting the by-laws were amended changing the

time for holding the annual meeting from the third to the second Thursday in June.

#### FISTULA OF THE ANTITRAGUS.

Dr. EZRA DYER reported a rare case of fistula of the antitragus. It was not a complete fistula, but a track about one centimeter deep, terminating in a blind sac and admitting an ordinary probe. The patient, a lady, had been annoyed for several years by a constant and offensive discharge and had consulted several surgeons who made ineffectual attempts to obliterate the sac. Dr. Dyer adopted the following plan. A curved needle armed with a small platinum wire and pointed with wax was carried along the passage to the bottom of the sac and thrust through the skin. The platinum wire thus placed *in situ* was detached from the needle, connected with a battery, raised to a white heat, and withdrawn. The operation was successful, though followed by greater pain than usually attends such use of the cautery.

#### RETAINED PLACENTA.

Dr. E. W. PENNY reported a case of retained placenta and exhibited the specimen. The patient, aged thirty-six, had been married ten years and had four children, the last born in November, 1881. After weaning the last child her periods returned regularly until January, 1884. In March following, supposing herself three months pregnant, she flowed profusely. During the next nine months she had irregular and at times very copious metrorrhagia but did not seek medical advice, as the flow was painless. Dr. Penny was called December 10th, and found her suffering violent expulsive pains, and an intrauterine mass resembling a fibroid presenting at the os. On removal it was found to be a placenta of apparently three month's development, which had undergone partial atrophy and cystic degeneration.

Dr. D. H. BATCHELDER called attention to the value of the dull wire curette in cases of incomplete abortion. He had never seen bad results follow its careful use.

Dr. J. H. ELDRIDGE exhibited a specimen of the witch-hazel, *Hamamelis Virginica*, gathered late in October while in full flower, with the fruit from the blossoms of the previous year in perfection, a freak of nature peculiar at the North to this order of plants.

Remarks on the astringent properties of *Hamamelis* were made by Drs. Brown, Garvin, O. C. Wiggins, and Ely.

#### REPEATED LITHOLAPAXY.

Dr. CASWELL reported the farther history of a case of stone upon which he operated by crushing two years ago. The patient did well until October last, when he passed three small calculi. December 2d Dr. Caswell crushed and washed out a small calculus. A second smaller stone was washed out uncrushed. In such cases it would be well at periods of six or nine months to have an experimental washing out of the bladder to remove any small stones that might have formed.

#### NATURE AND PREVENTION OF PUERPERAL FEVER.

Dr. FRANK B. FILLER read a paper on nature and prevention of puerperal fever. A disease

having no clinical history and no pathology peculiar to itself can hardly claim a place among specific diseases. The fact that puerperal fever frequently follows exposure to certain zymotic diseases is no argument against its septic character, for in ordinary surgical practice, especially in hospitals, we find that erysipelas, diphtheria, and scarletina will give rise to septicaemia. Different meanings are attached to the word septicaemia. The definition which includes blood poisoning from any infection, whether septic or from zymotic diseases would cover all cases of puerperal fever. Reference was made to the relation of this definition to the germ theory of disease and the probability that future investigations in this field will throw light on the connection between septicaemia in its puerperal form and the zymotics.

A source of puerperal fever that especially concerns us as practising physicians is by direct inoculation. Happily proof is abundant that only occasionally can the disease be ascribed to inoculation by attendants; but as it is a source of danger which can be controlled by physicians its consideration is of great importance. The physician should refrain from attending a case of labor when fresh from the presence of contagious diseases or from contact with septic materials. The hands of the physician should be thoroughly washed in some disinfecting solution before making a vaginal examination. All instruments used should be known to be clean and disinfected.

Care should be taken that no part of the placenta or membranes is left within the uterus or vagina. Firm contraction of the uterus should be assured and maintained after delivery. Sutures should be taken in all deep lacerations of the perineum. Bedding should be changed frequently, as also the napkins; and if any unnatural odor is detected from the latter, disinfecting vaginal douches should be used. Ventilation of the lying-in chamber must be secured.

Dr. NEWHALL opposed all theories and details of treatment growing out of germs believed in but not seen. Until the poisonous bacillus is found and described he preferred to remain unacquainted with it.

Dr. TERRY remarked that the theory that puerperal fever is a septic and not a zymotic disease is strongly supported by the fact that better results are obtained by basing treatment on that theory. The effective prophylaxis now carried out in prominent lying-in hospitals grew out of the recognition of the germ theory. Believing that septic germs cause the disease, we attempt by rigid antiseptics to prevent their introduction before confinement or to paralyze their action after confinement.

Dr. ABEL BALLOR objected to much meddling with nature's processes, and thought that our interference in way of treatment had sometimes more to do with causing septic puerperal fever than germs. Nature often overcomes these post partum difficulties better than we do. He referred to a case of sickness lasting three years caused by the unwarranted search for germs. He congratulated the younger members on their enthusiastic devotion to scientific progress, but cautioned them, in midwifery, to follow nature — the safest guide.

Dr. CRAWFORD hoped the society would not go

on record as doubting the doctrine of the septic nature of puerperal fever. Some recent directions for the management of labor cases are extravagant. Dr. Thomas's elaborate rules go beyond the necessities of ordinary cases. Stripping the chamber of furniture and carbolic washings of floors and walls are unnecessary in private practice, except in extraordinary instances. The safe middle course is best. In times of epidemic erysipelas or puerperal fever, greater precautions are needed.

Dr. ELY observed that parturition is not a pathological but physiological process and requires no routine guidance or interference. In all cases involving lacerations we need first of all absolute cleanliness. He doubted the necessity of intra-uterine injections. Their chief good is in washing out breaking down tissue and probably pure distilled water is as useful as anything for this purpose. He alluded to Klein's demonstration of the vitality of the bacillus of anthrax as illustrating the great tenacity of life of germs and spores.

Dr. O'LEARY believed that a physician should carry a sense of personal responsibility when attending a case of labor, but he should follow the dictates of common sense and avoid officious meddling, or merely following a fashion.

Dr. FULLER said that acceptance of the germ theory is not necessary to the recognition of septicaemia as a disease, and nearly all the authorities admit that puerperal fever is a form of septicaemia. Any known means of preventing septicaemia should be adopted.

#### INVESTIGATION OF THE PREMISES AND HABITATIONS OF THREE HUNDRED CASES OF TYPHOID FEVER.

Dr. G. TABER SWARTS read the statistics of an investigation of the premises and habitations of three hundred cases of typhoid fever occurring in Providence in the winter of 1882-83.

During this epidemic over five hundred cases of typhoid fever were reported to the city registrar. In compiling the results of the investigation by hundreds each succeeding series of one hundred cases gave the same results and the investigation was not pushed beyond three hundred cases. In this examination every endeavor was made to find some source of air or water contamination or other prevailing condition which might have a bearing in the production of the disease. At the same time doubtful instances of any defect were conscientiously excluded. The cases investigated were from the general practice of forty-two physicians and represent all classes of practitioners. Some of the most important of these statistics are as follows:—

#### AGE.

No. of Cases in Groups of Ten Years.	No. of Cases in Groups of Thirty Years.
1 to 10 . . . . . 70 cases.	1 to 30 . . . . . 251 cases.
11 to 20 . . . . . 112 cases.	31 to 60 . . . . . 47 cases.
21 to 30 . . . . . 60 cases.	61 to 75 . . . . . 2 cases.
31 to 40 . . . . . 29 cases.	
41 to 50 . . . . . 12 cases.	300
51 to 60 . . . . . 6 cases.	
61 to 70 . . . . . 1 case.	
71 to 80 . . . . . 1 case.	
300	

## EXPOSURE.

Other cases in the same house . . . 52 instances, or 17 per cent.  
Fellow-workmen having typhoid . . . 33 instances, or 11 per cent.  
Known exposure to typhoid . . . 37 instances, or 12 per cent.

122 . . . 40 per cent.

There was in forty per cent of the cases known exposure to the emanations of typhoid fever.

## HEATING OF HOUSES.

Concerning heating of houses, results were negative. Many complaints were made of air being contaminated before entering the furnace, as where lawns were covered with stable manure. One modern schoolhouse supplied over two hundred pupils with furnace-heated air drawn from within twelve feet of a privy vault hemmed in by a high board fence. It was frequently necessary to open the windows and close the registers to prevent introduction of foul odors.

## SEWER CONNECTIONS

existed in only twenty-eight per cent. of the cases. Seventy-two per cent. of all the cases were connected with cesspools or allowed waste to run on the ground near the dwelling.

There were many bad conditions external to the houses still sufficiently near to sleeping-rooms to be a source of danger. Thus

Swill thrown on the ground to decay . . . 10 instances  
Swill deposited in the privy vault . . . 14 instances  
Swill buried . . . 2 instances  
Swill stored in the cellar . . . 5 instances

A very common source of air contamination is found in

## PRIVY VAULTS,

which are located indiscriminately as regards distance from houses.

Vault emptied every three months . . . 13 instances  
Vault emptied every four months . . . 2 instances  
Vault emptied every six months . . . 48 instances  
Vault emptied every year . . . 72 instances

In one instance the vault had remained uncleared for two years.

## WATER SUPPLY.

Wells or pumps the only supply . . . 16 instances  
Wells for drinking, cisterns for washing, Cistern water the only supply . . . 2 instances  
Pawtuxet water, but well water for drinking . . . 10 instances  
Pawtuxet water, but cistern water for drinking . . . 2 instances  
Admitted that hot water from tank was used for cooking . . . 5 instances

53

Thus 53 cases or 17 per cent. used an impure water supply.

## OCCUPATION.

Indoor entirely . . . 252 cases  
Outdoor and in . . . 49 cases  
Outdoor entirely . . . 15 cases  
Not recorded . . . 4 cases

300

## PREVIOUS DISEASE IN THE SAME HOUSE.

Diphtheria . . . 1 to 2 years previous, 7  
Diphtheria . . . 3 to 4 years previous, 5  
Typhoid fever . . . 1 to 2 years previous, 2  
Typhoid fever . . . 3 to 4 years previous, 6  
Scarlet fever . . . 1 to 2 years previous, 45  
Scarlet fever . . . 3 to 4 years previous, 21  
Malaria . . . 1 to 2 years previous, 36

—81

That these figures should be larger there can be no doubt. A large part of the population are migratory, and the disease-record of a tenement is soon lost.

## SINKS

were found untrapped in 170 cases, and leakage under the sink contaminating cooking utensils was found in sixteen instances.

## SUMMARY.

Fair sanitary conditions were found in ninety-seven cases, or thirty-two and one-third per cent. Unsanitary conditions sufficient to be a factor in the production of disease were found in 203 cases, or sixty-seven and two-thirds per cent of the 300 cases investigated.

## Recent Literature.

*The General Practitioner's Guide to Diseases and Injuries of the Eye and Eyelids.* By LOUIS H. TOSSWILL, M.B., M.R.C.S., etc. London: J. & A. Churchill. 1884. 12mo. pp. 110.

This little volume is a very fair specimen of its class, but it belongs to a class of books which we believe to be of very little value, except perhaps to their authors or publishers. Mr. Tosswill has written it "knowing how little time the general practitioner can devote to professional reading, and to what frequent interruptions he is liable." If such a book as this be the measure of the time that a physician can devote to the study of diseases of the eye, it would be better that he should not attempt to treat those diseases at all.

*A Treatise on Ophthalmology for the General Practitioner.* Illustrated. By ADOLF ALT, M.D. Chicago, St. Louis, Atlanta: J. H. Chambers & Co. 1884. 8vo. pp. 224.

The author has attempted to prepare a work solely for the general practitioner, intended to serve as a guide as to when he may conscientiously take upon himself the responsibility of dealing with an affection of the eye, and when he had better not do so.

Within the limits thus assigned the task may be said to have been accomplished with large measure of success; certainly the book is very much better than most of those written avowedly with the above purpose. There is an avoidance of unnecessary detail and no useless padding. The descriptions of disease are generally clear so far as the prescribed brevity allows, and the directions for treatment judicious. Perhaps for readers unfamiliar with eye diseases too much latitude in the treatment is occasionally impliedly allowed. In speaking of gradual or forcible distention of strictures of the nasal duct, for instance, it would have been better to have expressed the choice more strongly than by saying, "The gradual distention is in most cases the preferable method." The wood-cuts are coarsely executed, but serve sufficiently well to give the desired idea, and that is, after all, the main point.

# Medical and Surgical Journal.

THURSDAY, JANUARY 1, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by CUPPLES, UPHAM & Co., Boston. Price, 15 cents a number; \$5.00 a year, including postage.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUPPLES, UPHAM AND COMPANY,

281 WASHINGTON STREET, BOSTON, MASS.

## A NEW YEAR.

With this number THE BOSTON MEDICAL AND SURGICAL JOURNAL enters auspiciously with the first day of the new year upon the fifty-seventh year and the one hundred and twelfth volume of continuous publication under its present title. It began in February, 1828, as the result of the union of two predecessors, of a quarterly published for fifteen years—from 1812–27—as the *New England Journal of Medicine and Surgery and Collateral Branches of Science*, and for one year as the *New England Medical Review and Journal*, with a weekly published for five years—1823–28—as the *Boston Medical Intelligencer*.

At the time this consolidation took place, and the JOURNAL was given its present name and weekly issue, there were in existence in the United States eight medical journals, of which the *American Journal of Medical Sciences*, a quarterly started in 1820, alone survives, we believe. The *London Lancet* was begun in 1823, the *Medical Times and Gazette* in 1827, the *Edinburgh Medical and Surgical Journal*, a monthly, in 1805.<sup>1</sup>

Since its first volume in 1828, this Journal has had several publishers. In 1835 it was first issued by Mr. David Clapp, who acquired the property, and continued to publish it until 1875, it having been previously purchased, in 1873, by a number of well-known medical gentlemen with the object of making it on broad grounds as serviceable as possible to the medical profession, and placing it above partisan or commercial bias. Since 1875 the JOURNAL has been published at the Riverside Press, and its title-page has borne the imprint of H. O. Houghton & Co., Houghton, Osgood & Co., and Houghton, Mifflin & Co. The second contract with the Riverside Press having expired with the past year, a new contract for publication has been made with the firm of Messrs. Cupples, Upham & Co., of Boston.

In the process of evolution, and in the desire to meet the growing wants of the medical public,

the form and size of the JOURNAL have been changed several times, and the double and single column pages have yielded to each other more than once. The present size, form, and attractive typographical appearance were adopted in 1880, and will be continued in all respects without change, having proved themselves satisfactory, unless at some future date it should seem desirable to increase the number of pages.

Under the new contract for publication, the JOURNAL will enjoy increased advantages, and with them it is believed an increasing field of usefulness and prosperity. An immediate proximity of the printing-office to the editorial-office will greatly facilitate that prompt appearance of the latest intelligence and reports of meetings, which, as well as carefully prepared original articles, it is the aim of an active, energetic weekly medical newspaper to furnish. The respectable age of the JOURNAL will not deter it from making use of the telegraph, should that seem likely on any occasion to furnish information of genuine value to its readers, but electricity will not be resorted to merely as a means of display.

The editorial-office, at the "Old Corner Bookstore," on Washington Street, so well-known all over our country, and associated with literature, in fact, wherever English books are read, brings back to that building once more medical interests for which it was formerly best known, and, in uniting the past and the present, joining medicine with literature, finds itself appropriately placed. Many of our readers outside of New England, who are perfectly familiar with this oldest building save one in Boston, either by name or by sight, as a centre of literature, can hardly be expected to know that it was built in 1712, one hundred years before the appearance of the first number of the *New England Journal of Medicine and Surgery*, by Thomas Crease, the principal apothecary of the town in that day. In 1816 it again sheltered the *material medica* under its roof, being occupied by Dr. Samuel Clarke, the father of our distinguished townsman Rev. James Freeman Clarke, and it was not until 1828 that it became a home for books and authors.

We therefore feel that, in taking up our quarters in this famous old building around which surges to-day the very busiest life of an active, eager modern city, we harmonize all the interests to which it has been devoted, and not unfitly see typified in it, and in the JOURNAL which now enjoys its hospitality, a respect for the past and for conservatism combined with an adaptability to and sympathy for the changing wants and aspirations of the present and future.

The word BOSTON is retained in our title for the sake of *auld lang syne*, but every occurrence of professional importance, whether within or without the borders of New England, will receive prompt and impartial notice at our hands.

<sup>1</sup> Those who are curious for further details in regard to medical journals are referred to a paper by Dr. J. S. Billings, in this Journal, vol. c. p. 1.

## THE EVOLUTION OF THE TREATMENT OF EMPYEMA.

RECENTLY the admitting physician of a prominent hospital sent a communication to the medical board asking whether, in future, cases of empyema should be admitted on the medical or the surgical side,—a question which illustrates at once the depth of shading of parts of the line separating medicine from surgery and the evolution of the treatment of empyema. It is on this latter point that we propose to say a few words.

From the earliest times empyemata were opened occasionally, but at so late a period in the course of the disease that recovery can seldom have been more than partial. Until Auenbrugger and Laennec taught us how to distinguish accurately between affections of the lung and of the pleura at the bedside it may be said with truth that the lot of the possessor of a purulent pleural effusion was a hard one; he rarely had even that satisfaction which comes from knowing what is one's disease before the pus made its way through the chest wall and opened into a bronchus, if happily it did not choose some less favorable avenue of escape. For many years later, indeed, the finer methods of diagnosis bore but little therapeutic fruit, the evacuation of pleural effusions by the trocar or knife being practically considered unwarrantable, save as a last resort in desperate cases, accurate diagnosis necessarily preceding rational treatment by a longer or shorter interval.

The next great step in advance was taken on this side of the Atlantic, when Bowditch showed that fluid can be withdrawn from the chest with ease and safety at any stage of the disease, and that the danger of wounding the lung, diaphragm, or liver could be disregarded. The aspirator was then improved by Dieulafoy, and it was gradually ascertained that, while with the aid of that instrument we had gained the mastery over the great majority of cases of serous and sero-fibrinous effusion, the simple operation was rarely of more than mere temporary service in empyema. In children, it is true, one or more tapings sometimes proved curative, but adults were apt to succumb sooner or later to tuberculosis or some complication. It was then more clearly seen that an empyema must be treated like any other abscess, by free incision, and the advantages of an early operation were more and more appreciated, the antiseptic method and thorough drainage contributing materially to progress. We now found ourselves in a position to deal satisfactorily with those cases in which, between expansion of the lung and falling in of the chest wall, obliteration of the cavity could be obtained; but a not inconsiderable number of cases remained in which the lung was so hopelessly bound down by adhesions that a permanent thoracic fistula with good drainage seemed the best result which could be reasonably hoped for.

Already more than twenty years ago Roser suggested the excision of a portion of a rib in order to obviate the difficulty often met with in keeping the fistula open, owing to the approximation of the ribs in the process of contraction of the chest; and, with the same end in view, Lungenbeck revived the operation said to have been done by Hippocrates of boring through a rib, but with the comparatively modern instrument, the trephine. It was found that no bad results followed these operations on the bone, and Estlander was led to reason that if a portion of one rib can be removed without ill consequences, several could be treated in the same way, and then the permanent closure of intractable empyemata be brought about. Putting his idea into practice, the latter observer found that it stood the test, and the thoracoplasty operation, or the excision of ribs in such number and extent as may be required to bring the chest walls and remains of the lung in apposition, is the last great advance which has been made in the treatment of interthoracic effusion.

This operation has been done a number of times in this country during the last few years, but does not seem to be so widely and favorably known as it deserves to be. It is not difficult, and has yielded excellent and speedy results in some cases which have come to our knowledge. Only a day or two ago we met on the street a man whose chest at one time had been opened for empyema, but who remained in hospital for months with a moderate sized suppurating cavity. The subsequent excision of a portion of a few ribs effected a cure, and the man has now resumed his former work. The more promptly and thoroughly empyemata are opened the fewer cases will require the operation on the ribs; but the lung is sometimes seriously bound down at an early stage of the disease, and for these cases we are now able to afford relief.

## PATHOGENY AND TREATMENT OF DELIRIUM TREMENS.

The pathogeny of delirium tremens is still a matter of dispute—not that there is any doubt as to the principal causal factor, but there is not precise agreement as to the relationship of the toxic agent to the special phenomena of the disease.

According to one view delirium tremens is a peculiar kind of cerebro-spinal crithism, with disorder and depression of all the functions of animal and organic life, caused by the continued irritation of alcoholized blood, or, as Dr. B. W. Richardson suggests, blood charged with impure alcohols, of which potato spirit is the type. There is a marked analogy (regarding it in this light) between *ataxia à potu* and the ataxic delirium of typhus or typhoid fever, and the tremulousness of the voluntary muscles much resembles the shaking paralysis of mercurial poisoning—the *tremblement*

*mercuriel* of French pathologists. According to the second view, held by the late Dr. Watson, and defended at the present day by Jaccoud, delirium tremens "is a disease of exhaustion or irritation of nervous power, having the habitual use of intoxicating liquors for its predisposing, and the abstraction or diminution of the accustomed stimuli for its exciting, cause."

An inebriate, for instance, has been on a long carousal, during which little or no food has been eaten, and the brain has been in a craze from liquor; he comes to a point where he can take no more stimulant—either he now loathes it, or the stomach rejects it, or both—and he has an attack of the "horrors." According to the first theory the attack is due to excess of the stimulus, the alcohol acting as a paralyzing agent; the second theory attributes the cerebro-spinal ataxia to "insufficiency of the stimulus"; in other words, the nerve centres having been long equilibrated under alcohol become depressed and fall into disorder when the stimulant is withheld. It would be a therapeutical outcome of the first theory to enjoin entire abstinence from spirituous liquors, and of the second theory to prescribe them in suitable quantities as adjuncts to cure.

In endeavoring to form a proper estimate of the pathogeny of this affection, and thus get hold of the rational indications of treatment, it will not do to lose sight of the prime fact that the disease is an acute epiphenomenon of chronic alcoholism, and that it depends essentially on blood poisoning by the fiery products of the still, being especially prevalent in countries where distilled liquors—in preference to the lighter fermented beverages—form the customary intoxicant. This being the case the leading indication must always be suppression of the cause. It would almost seem as though nature intelligently recognized this indication, and attempted to realize it in the loathing of liquor, which the drunkard at a certain stage experiences; if, despite this loathing, he persists in imbibing the alcoholic potion, the stomach speedily rejects it by vomiting. And here is where the two views meet and harmonize. The man who is in a state of preparedness for delirium tremens is one whose nervous system is in a highly irritable, unstable condition from strong drink; he has for some time been unable to eat or digest, and has become further weakened in consequence; the time, moreover, has arrived when, owing to saturation of the system with the poison so that it will bear no more, he can take no more alcohol, and this is "the last blow that brings him down." The issue may be precipitated by a traumatism, as a severe injury to the head, or a fracture, by its prostrating influence upsetting the nervous equilibrium even more than taking from the system the prop of alcohol could do. An attack of pneumonia, erysipelas, acute

rheumatism, even severe mental emotion from business losses, disappointment, etc., any great physical or mental shock, may be the immediate antecedent, just as the snapping of the gun-lock causes explosion of the powder in the barrel.

The therapeutics of delirium tremens must recognize the poisoned state of the blood, the weakened state of the vital forces, and the perturbed, irritable, ataxic condition of the nervous system, which finds expression in the restlessness, agitation, and sleepless delirium, as well as in the tremulousness of the voluntary muscles. The first and most imperative indication is to stay the waste of nervous energy and nerve substance, which, if too long continued, may wear out the patient. Here is the principal danger of the disease. It is true that delirium tremens is a self-limited disease, as Dr. Ware a long time ago pointed out, and that the patient, if brought under suitable hygienic influences, will very often get well without medicine; it is no less true that the violence and duration of the disease may be very much moderated; that the attack may even (as there is reason to believe) be cut short by suitable sedative, anodyne, and waste-restraining treatment.

The discovery of the hypnotic effects of the bromides, and especially of hydrate of chloral, almost ushering in a new era in the treatment of delirium tremens, and now moderate doses, which may be regarded as absolutely safe, of hydrate of chloral have replaced in the practice of most physicians the large and sometimes dangerous doses of opium which were formerly deemed necessary to quell the fury of the attack. When it was sought to control the disease by bromide of potassium (a very natural and successful mode of treatment), it was found that rather large quantities of this salt were required—half a drachm or more repeated every hour. These doses were not without serious disadvantages in further enfeebling the digestive powers, and in depressing the functions of the spinal cord. The dose of chloral indicated in order to produce a hypnotic effect is very much less, and the inconveniences attending this medicament are so trifling that, in words of Balfour: "We seem to possess in hydrate of chloral a remedy which in all cases, from the slightest to the most severe, acts rapidly, safely, and efficiently, *cito, tuto, et jucunde*, and which seems to deprive indulgence in drink of all its horrors, and nearly all its dangers."

As for the administration of opium in *mania à potu*, we believe that it is now the experience of all practitioners that in cases where it is desirable to resort to opiates in conjunction with chloral, hypodermic injections of morphia claim the precedence of all other modes of exhibition. There will be continually instances of unusual obstinacy and severity, where the morphia injection will be a valuable auxiliary to treatment, rendering necessary

much smaller doses of chloral. There is no doubt that in capicum we have a useful stimulant in delirium tremens, as in other forms of chronic alcoholism. This drug may be given in the form of tincture along with the hydrate of chloral. There is considerable evidence in favor of the utility of pretty large doses in this disease.

A judicious eliminative treatment should be carried out as opportunity offers; the action of the skin and kidneys should be favored by suitable diaphoretics and diuretics (ammonia, camphor, and salines); the bowels should be kept open by an occasional saline laxative. After all it is doubtless true that suitable nourishment is the best depurant, and that, as Perrie observes, "we cannot look for much improvement in the condition of the sufferer till his blood has been freed to a certain extent from its poisonous ingredients, and made richer in quality by the persevering exhibition of proper food, and so rendered more suited for the purposes of nutrition." To this and the frequent administration of meat broths—and here beef peptones are handy and useful—and milk (when borne) is a *sine qua non*; the importance of muscular rest, as well as of mental quietude, must also ever be kept in mind.

---

#### STATE REGULATION OF MEDICAL PRACTICE IN PENNSYLVANIA.

THE Philadelphia County Medical Society has recently held a number of extra meetings to consider the draft of a bill to create a State Board of Examiners and Licensers, formed by a committee appointed for the purpose. The committee held several conferences with similar commissions from the Medical Jurisprudence Society, Philadelphia, and the Pennsylvania State Medical Society, at some of which a committee of the Homoeopathic State Medical Society was present.

The Committee of Conference agreed to present a report to the county medical societies throughout the State, recommending a bill whose principal feature was the creation of a mixed board of examiners, consisting of seven physicians and seven homoeopathic physicians, this being claimed to be the relative proportion of the homoeopathic school to the unadorned and unexclusive portion of the profession.

The provisions of the Act are only applicable to those commencing practice after September 1, 1886, and require examination before the Board and the possession of its license as necessary prerequisites to registration and practice. For the examinations upon therapeutics and practice of medicine it is proposed to have two sets of papers, one homoeopathic and the other scientific, the candidate being allowed to select which of the two he will be examined upon, it being kept secret which he selects until he has passed upon the other branches.

Societies have already signified their approval of the bill, but the Philadelphia Society, keeping up its reputation for conservatism, seems willing rather to bear with present ills than rush into unknown perils. Some of the principal members of the society are uncompromising in their opposition to a mixed board, and consider it in the highest degree unwise to endorse practitioners of any exclusive sect in medicine by such a course as contemplated in this bill. It is also believed that the medical schools are looking askance at it, uncertain whether to join their influence with that of the general profession throughout the State, or to holdily enter the lists and fight the bill because it may be prejudicial to their interests and interfere with their vested rights, by establishing a sort of censorship, which is distasteful to those schools that like to follow the go-as-you-please system of teaching.

In the meantime, incompetent and irregular practitioners of medicine who are driven away from other neighboring States are descending upon the fertile valleys of Pennsylvania, like a horde of locusts; unfortunately they do not observe any times or seasons, but come to stay permanently or as long as they are made welcome.

---

#### MEDICAL NOTES.

##### NEW YORK.

—One of the most familiar characters in the New York medical world has passed away in the person of Dr. William Darling, for many years the distinguished Professor of Anatomy in the University Medical School, who died on Christmas morning, at the age of eighty-two. He was born at Dense, Scotland, and in the year 1830 came to America and began the study of medicine at the university with which he has so long been connected. It was more than ten years after this, however, before he would consent to come up for his degree; although he was all the time engaged in the enthusiastic pursuit of his studies, and had in the meanwhile made for himself a reputation as a teacher of anatomy. After being graduated, in 1842, he went to England, and there became a Fellow of the Royal College of Surgeons, remaining abroad until 1862. He then returned to New York, and soon afterward was appointed to the professorship at his *alma mater* which he has filled with so much honor ever since. He retained his zeal for his professional studies up to the last, and his anatomical collection is one of the finest in the country. In addition, however, he was a profound mathematician and was remarkably well versed in the whole range of poetical literature; while he was himself a poet of no mean attainments. It is said that during his residence in London a twisted paper was once found in the cavity of a young girl's skull among some specimens,

which contained an anonymous poem of his of such extraordinary merit that a reward of fifty pounds was offered for the name of its author. Dr. Darling wrote only two scientific works, "A Small Compend of Anatomy," and "Essentials of Anatomy."

—On the twentieth of December a woman, twenty-seven years of age, who had recently been confined, died suddenly from fright, in consequence of a slight fire which occurred in the tenement-house where she resided.

—The New York Young Men's Christian Association, in a recent debate, decided that "physicians should be Christians." The *Springfield Union* agrees to the decision, but thinks it a mistake to draw the line at physicians: their patients should be included.

#### PHILADELPHIA.

—The University of Pennsylvania has, during the past month, opened two new departments: a School of Biology, which will be under the direction of Professor Joseph Leidy and Dr. Horace F. Jayne, and a Department of Physical Culture under the charge of Dr. J. William White, who is president of the University Athletic Association, and who is clothed with the authority and title of Professor, and has a seat in the Faculty. This department will be modelled after that of Harvard University. The school of biology has a separate structure for its uses situated on the grounds of the university. The new building is of brick, and is two stories in height: the upper floor is devoted to laboratories, library, and private rooms; the first floor has the lecture-room, museum, and working-rooms, while in the basement are a large aquarium and storage-rooms. The object of this new school, which is modelled after the Johns Hopkins School, is the encouragement of individual and original biological research. A zoological station at Naples under the charge of Dr. Dollay, of Rochester, has been established. It is intended that the work of the new school will be published in monographs or journal form. The Faculty of this school consists of William Pepper, M.D., LL.D., Provost of the University and *ex officio* President of the Faculty; Joseph Leidy, M.D., LL.D., Professor of Anatomy, Director of the Biological Department; Joseph T. Rothwick, M.D., B.S., Professor of Botany; Harrison Allen, M.D., Professor of Physiology; Andrew J. Parker, M.D., Ph.D., Professor of Comparative Anatomy; Horace Jayne, M.D., Professor of Vertebrate Morphology; Benjamin Sharp, M.D., Ph.D., Professor of Invertebrate Morphology; N. Archer Randolph, M.D., Instructor in Physiology. In the Medical Department recently Edward T. Bruen, M.D., has been elected Professor of Physical Diagnosis, and Louis Starr, M.D., Clinical Professor of Diseases of Children.

—Nearly a year ago the State Board of Charities appointed a sub-committee, under the chairmanship of Dr. John G. Morton, to investigate certain cases of alleged improper detention and ill-treatment of insane persons, especially outside of asylums, in various parts of the State. Although there is a very good lunacy law, it failed of efficiency because it was not made the duty of any one to see it properly enforced; the neighbors who are in possession of such knowledge of illegal detention and abuse of insane patients rarely are willing to publicly appear as informers. The Lunacy Board seemed to be just what was needed; they have received confidential letters from all parts of the State and have investigated eighteen cases, some of which had been kept chained in outhouses, poorly fed, and exposed to bad weather, for many years. One patient had been thus kept like an animal for sixty-five years. Another patient, to whom attention had been called, was burned to death by an accidental fire before he could be removed from his den. Very little opposition has been encountered by the committee in its investigations, and its directions with regard to the placing of the insane under proper care are usually promptly complied with.

—A crematorium was opened at Lancaster on November 25th.

—Two more cases of acute facial erysipelas have been treated in Professor DaCosta's wards at the Pennsylvania Hospital, by hypodermic injections of pilocarpin muriat (gr.  $\frac{1}{4}$  to  $\frac{1}{2}$ ). The injections may have to be repeated, or supplemented by the fluid extract of Jaborandi, the object being to produce free diaphoresis; but if the case be in its incipient stage, the results are almost magical—the erysipelatous symptoms entirely disappear. During convalescence, a course of iron was found to be advantageous. No relapses have thus far been noticed. No special effect upon salivary glands or kidneys was observed. At the last meeting of the College of Physicians, Professor DaCosta called attention to the hypodermic use of cocaine in cases of cardiac failure and weak heart. He had found that doses of one third to two thirds of a grain strengthened the cardiac systole, and, as shown by the sphygmograph, the pulse became fuller, stronger, and a little slower. Given in this way it was observed that the pupils became dilated, but the effect upon sensibility of mucous membranes was only slight, and not comparable to those following its local employment. Injected into the skin it produced a wheal which was insensible, but thrown under the skin no local anesthesia was produced.

#### CHICAGO.

—One of the professional topics of the hour here just now is a local dispute about a case of so-called "lumpy jaw" in the human subject. The dispute began among the doctors, then it got into

the secular papers, and now the *Medical Review* has taken it up, has quoted in detail and *ad nauseam* from the daily papers the strictures of one doctor upon another, and then of a third upon the first, and, to make the matter worse, the editor castigates the doctor who could be so rash as to have two cases of so rare a disease within four months, refers to the first and chief calumniator of a professional brother as the victim, and says he himself—the editor—has had ocular evidence that the “lumpy jaw” was a simple abscess, since, after being freely evacuated, it had promptly closed up.

The case referred to is one of the two on which *The Boston Medical and Surgical Journal* commented editorially some weeks since as having occurred in the practice of Dr. J. B. Murphy.

The diagnosis was not made in either case till both the patient and the microscopic specimens had been carefully examined by a number of physicians, among whom was Dr. Christian Fenger, who, as a pathologist, probably has no superior in the North-west. It was the unanimous judgment of the council in each instance that true actinomycosis existed. The first case, which was much the worse of the two,

underwent a most thorough scraping of all the sinuses of the enlargement, healing took place, and the disease has not returned. The other case was less thoroughly scraped, and healing followed. But the disease returned; so did the patient, when, informed of the true nature of his trouble, he straightway consulted another doctor, who, without making a microscopical examination, declared the thing a simple abscess, opened it, and now reports it healed. Meanwhile he exhibits the case to a considerable number of other medical men, and appears greedily to seize the opportunity to tell all about it, with the corroborating opinions of his medical friends, and his own opinions of his medical enemies, to a newspaper man who enjoys nothing so much as to get a lot of doctors quarrelling, and who prints the whole story with amplifications, and in a way to make the profession feel as though its clothes were too large for it. Next Dr. Murphy reads a careful report of his cases before the Medical Society and exhibits his specimens, whereupon Dr. Fenger reaffirms that they were cases of actinomycosis, and his views are warmly endorsed by Dr. Belfield.

## REPORTED MORTALITY FOR THE WEEK ENDING DECEMBER 20, 1884.

Cities.	Estimated Population.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 2,333; under five years of age, 805; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrheal diseases) 490, lung diseases 491, consumption 397, diphtheria and croup 200, scarlet fever 66, measles 53, typhoid fever 48, diarrheal diseases 25, malarial fever 22, whooping-cough 16, erysipelas 14, cerebro-spinal meningitis, nine, puerperal fever six. From *measles*, New York 27, Cincinnati eight, Chicago and Gloucester five each, Brooklyn three, Philadelphia two, Baltimore, Fall River, and Newton one each. From *diarrheal diseases*, Cincinnati nine, New York, Chicago, Boston, and Nashville three each, Baltimore two, Charleston and Springfield one each. From *typhoid fever*, Brooklyn six, Chicago four, Baltimore three, New York, Philadelphia, and Charleston two each, Cincinnati, Nashville, and Springfield one each. From *whooping-cough*, New York six, Chicago, Boston, and Baltimore two each, Brooklyn, Nashville, Charleston, and Lynn one each. From *erysipelas*, New York four, Brooklyn and Baltimore three each, New Haven two, Chicago and Nashville one each. From *cerebro-spinal meningitis*, New York six, Philadelphia, Chicago, and Cincinnati one each. From *puerperal fever*, Chicago four, New Haven and Newton one each. From *small-pox*, Philadelphia one.

In 102 cities and towns of Massachusetts, with an estimated population of 1,286,111 (estimated population of the State 1,955,-

104) the total death-rate for the week was 18.15 against 18.00 and 19.29 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,762,354 for the week ending December 6th, the death-rate was 24.4. Deaths reported 4,102; infants under one year of age 942, acute diseases of the respiratory organs (London) 499, measles 80, scarlet fever 76, whooping-cough 63, fever 52, diphtheria 42, small-pox (London) 37, diarrhoea 35.

The death-rates ranged from 18.4 in Portsmouth to 38.7 in Oldham; Birkbeuland 25.8; Birmingham 24.8; Bradford 25.4; Bristol 21.8; Leeds 21.7; Leicester 24.4; Liverpool 26.0; London 22.5; Manchester 25.8; Nottingham 26.7; Sheffield 23.1; Sunderland 30.9. In Edinburgh 22.2; Glasgow 37.5; Dublin 33.2.

For the week ending December 6th, in the Swiss cities, there were 27 deaths from consumption, lung diseases 24, diarrheal diseases 11, diphtheria and croup 13, measles 5, whooping-cough four, typhoid fever two, puerperal fever one. The death-rates were, at Geneva, 13.2; Zurich 3.9; Basle 20.1; Berne 28.9.

The meteorological record for the week ending December 20th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Date, December, 1884.	Barom- eter.	Thermometer.			Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM DECEMBER 20, 1884, TO DECEMBER 26, 1884.

WALKER, P. G., first lieutenant and assistant surgeon. Received duty in Department of Colorado, and ordered to Department of Arizona. S. O. 128, Division of the Pacific, December 17, 1884.

ERIVLUM.—On page 619 of the JOURNAL, December 25, for Dr. F. N. Otis, read Dr. George A. Otis.

DEATH. Died, in Boston, December 26, 1884, William Henry Thornlike, M.D., M.M.S.N., aged sixty years and six months.

#### SOCIETY MEETINGS.

STUTTGART DISTRICT MEDICAL SOCIETY.—Surgical Section. There will be a meeting of the Section at 19 Boylston Place on Wednesday evening, January 7, at eight P.M. Communication: Five successful cases of Ovariectomy. By Dr. J. W. Elliot.

GASTROLOGICAL SOCIETY OF BOSTON. The Annual meeting will be held at 19 Boylston Place on the second Thursday of January, at four o'clock P.M. The Annual Address will be given by the President, Dr. H. O. Marey. Lunch will be provided.

H. J. HARRIMAN, M.D., 1881 Secretary.

J. PICKERING PUTNAM, Esq., and PROF. T. M. CLARK will deliver a lecture before the Society of Arts, Massachusetts Institute of Technology, Friday evening, January 2, at eight o'clock, on Sanitary Plumbing and our Plumbing Laws. Members of the medical profession are cordially invited.

BOOKS AND PAMPHLETS RECEIVED.—The Story of My Life. By J. Marion Sims, M.J., LL.D. Edited by his son, H. Marion Sims, M.D. New York: D. Appleton & Co. 1884.

Home Again! A Synopsis of a Tour Abroad. By Edward Borek, A.M., M.D., of St. Louis, Mo., one of the Delegates at the International Medical Congress, held at Copenhagen, Denmark, August 10-16, 1884.

The Basic Pathology and Specific Treatment of Diphtheria, Typhoid, Zymotic, Septic, Scorbatic and Putrescent Diseases Generally. By George J. Ziegler, M.D. Philadelphia: 1884.

Fifteenth Annual Report of the Manhattan Eye and Ear Hospital, with Throat and Nervous Departments. New York, October 15, 1885, to October 1, 1884.

Notes on the Opium Habit. By Asa P. Meyler, M.D. Third Edition, Revised and Enlarged. New York: G. P. Putnam's Sons. 1885.

The Plaster-of-Paris Dressing in the Treatment of Fractures. By W. O'Daniel, Bullard, Ga. (Reprint from Transactions Medical Association. Georgia.)

Transactions of the Medical Society of the State of Pennsylvania at its Thirty-fifth Annual Session. Held at Philadelphia, May 11-16, 1881. Vol. XVI. Published by the Society. 1884.

A Pharmacopoeia for the Treatment of Diseases of the Larynx, Pharynx, and Nasal Passages, with Remarks on the Selection of Remedies and Choice of Instruments, and on the Methods of Making local Applications. By George Morewood Jeffers, M.D., etc. etc. Second Edition, Revised and Enlarged. New York and London: G. P. Putnam's Sons. 1881.

Modern Medical Therapeutics: a Compendium of Recent Formulae and Specific Therapeutical Directions. From the Practice of eminent contemporary Physicians, American and Foreign. By George H. Napheys, M.D. Edited by Joseph F. Edwards, M.D., and D. G. Brinton, M.D. Eighth Edition, Revised and Enlarged. Philadelphia: D. G. Brinton. 1885.

EXPLORATORY ABDOMINAL INCISIONS.<sup>1</sup>

BY JOHN HOMANS, M.D.

I HAVE been trying for a long time to report a number of miscellaneous cases of abdominal surgery. In the list will be found simple exploratory incisions: exploratory incisions followed by puncture and emptying of cysts; incisions followed by opening of the cyst, sewing it to the abdominal walls, and draining it; incision and partial removal of tumors; removal of ovaries and tubes for the cure of hysterotomia; for the cure of mania; for the cure of uterine fibroids; incision and drainage of interperitoneal abscess; exploratory incisions for intestinal obstruction followed by the establishment of artificial anus; supravaginal hysterectomy; nephrotomy for removal of renal calculi; nephrotomy for renal cancer; removal of immense myxolipomata; removal of a fibroid tumor of the peritoneum and abdominal fascia.

As I have already reported many cases of ovariectomy it seems proper that I should report some of these other operations done for the relief of abdominal disease, and in the outset let me say that the mortality will be found to be much higher in this list of cases than in ovariectomy. This higher mortality as compared to ovariectomy is to be attributed mainly to two causes: first, to the greater gravity of some of the operations, and secondly to the smaller experience of the operator in these cases as compared to his experience in the removal of ovarian tumors.

I believe that I have opened the abdominal cavity about two hundred and fifty times. Eleven of these operations were simple exploratory incisions followed by the removal of ascitic fluid, and affording an opportunity for visual and manual exploration of the interior of the abdomen. In this paper I will give an account of a certain number of exploratory incisions, and I shall hope to describe the other operations at some future time.

All these exploratory incisions were done antiseptically and under the carbolic spray.

**First Exploratory Incision.**—December 18, 1878. Patient sixty-two years old, a widow. Recovery. The patient was so large and the respiration was so embarrassed that it was necessary to place her upon her side, and this position made her abdomen so pendulous that I had to kneel on the floor and cut upward. About fifty pounds of ascitic fluid ran out of the peritoneal cavity, and, relieved of this pressure, the patient could breathe lying on her back. The tumor was found to be solid and friable, and immovably attached to the sacrum and ilium. Entire relief for many months to all the distressing symptoms was the result of this operation, and the fluid never reaccumulated. Dr. W. S. Brown, of Stonham, the patient's attending physician, and myself, both thought the tumor an ovarian cyst before the operation, but the abdominal walls were so thick and fat that it was impossible without aspirating to determine this question. After several months of comfort the tumor began to grow, and

the patient died a year after the operation. At the autopsy a soft, solid tumor involving the lower abdominal and pelvic viscera and parietes was found.

**Second Exploratory Incision.**—February 22, 1881. Patient forty-eight years old, a widow. Recovery. About twenty pounds of ascitic fluid removed. Tumor, a papilloma of the right ovary adherent to the pubes, rectum, ischium, and pelvic organs generally. The cyst had burst in the pubic region. After recovery the fluid reaccumulated and the patient died about nineteen months later. Dr. Abner Post kindly told me the result of the autopsy which showed papillomatous growths attached to and scattered over all the abdominal contents.

**Third Exploratory Incision.**—September 21, 1881. Patient twenty-one years old, unmarried. Recovery. A large amount of ascitic fluid was removed, many thin-walled, blue-colored cysts attached to the peritoneum and intestines were seen, and the pelvis was more or less occupied by a friable-feeling tumor filling the right side; its exact attachments were not made out, but it was immovable and was not interfered with. The patient recovered. Dr. J. W. Elliot tapped her on February 2, 1882 (five months after the operation), and, after the ascitic fluid had run out, he saw beneath the abdominal parietes a hard tumor about as large as a pregnant uterus of six months. On April 14th, he tapped her again; this time the fluid was bloody, and the tumor was somewhat larger. On June 28th he again tapped: the tumor was no larger, and the fluid was clear. She was able to go about, but was very thin. In the meantime another physician had tapped her. Dr. J. Foster Bush also treated her, and has written me the following letter:—

November 23, 1884.

DEAR SIR,—In reply to your note of Monday I would say that I saw Miss H. A. R. in the fall of 1882. Her general condition was extremely bad; there was hectic, anæmia, and extreme prostration, she being confined to her bed. The cicatrix of your exploratory incision had the appearance of a keloid, and in the right iliac fossa there was a tumor about the size of a quart bowl. In this locality she complained of constant pain, which was augmented by motion. The pain was so severe that she required opiates to produce sleep. I arranged to come in a day or two and tap her, but when I went to perform that operation I found that the tumor had opened spontaneously, discharged what she described as a "thick yellowish fluid," the amount of which she could not estimate. I put her on tonic treatment and a liberal diet. Soon she moved away and I lost sight of her till October, 1884, when she told me that she was well, was working regularly from morning till night, and was only troubled occasionally with pain in her side. After the rupturing of the tumor the yellow discharge had troubled her for a long time.

Very truly yours,

J. FOSTER BUSH.

Dr. John Homans.

Dr. Bush tells me that when he saw Miss R. she was rosy and healthy. I have been unable to find her. Her case is certainly a very remarkable one if the tumor has disappeared.

**Fourth Exploratory Incision.**—August 18, 1881. Patient thirty-six years old, married. Recovery. A small amount of ascitic fluid. Tumor a sarcoma, but so generally adherent that its origin could not be determined. Subsequent history of the patient unknown.

**Fifth Exploratory Incision.**—August 21, 1882. Patient thirty-nine years old, single. Death. Tumor universally adherent; it had a thick vascular feel, and on incision to the depth of an inch bled freely. She died of septicæmia on the fifth day.

<sup>1</sup> A paper read before the Boston Society for Medical Improvement, December 22, 1884. See page 10, No. 1, Vol. xli.

At the autopsy, the body was found full of gas and rapidly decomposing. The tumor was inseparable from the intestines: originally it had sprung from the left ovary.

*Sixth Exploratory Incision.*—September 20, 1882. Patient thirty-seven years old, single. Recovery. A moderate amount of ascitic fluid was found, and on digital exploration large malignant tumors of the omentum, liver, intestinal organs, and ovaries, were felt. The patient went to Burlington, Vermont, and died in March, 1883.

*Seventh Exploratory Incision.*—May 8, 1883. At the Free Hospital for Women. Tumor adherent, sarcomatous looking. Recovery. Patient went home and was heard from in July, growing larger and suffering much. Her subsequent history is unknown to me, but she has probably died.

*Eighth Exploratory Incision.*—August 9, 1883. Patient sixty years old, married. Death. General abdominal cancer. Thirty pounds of ascitic fluid removed. Patient died on the fourth day.

*Ninth Exploratory Incision.*—March 22, 1881. Patient sixty-six, widow. Recovery. Many pounds (ten or more) of ascitic fluid ran out of the incision and as much more gelatinous-looking material. The omentum had become an elongated tumor of a pinkish coral color; the spleen was enlarged and in the same condition. Nodules of cancer were felt among the bowels, a wall of cancerous tissue shut off the pelvis and its organs from the abdominal cavity. The patient recovered entirely from the operation and died in September, 1881.

*Tenth Exploratory Incision.*—June 13, 1881. Patient seventeen years old, single. Death. The intestines were found matted together when the abdomen was opened, and beneath them an elastic swelling was felt. No fluid could be obtained by aspiration. Neither the uterus nor ovaries could be felt by the hand in the abdomen. The patient died on the fifth day of septicaemia. At the autopsy the Fallopian tubes were found to be in a state of tubercular salpingitis and the cheesy mate-

rial extended upward on both sides of the abdominal cavity nearly to the diaphragm.

*Eleventh Exploratory Incision.*—June 19, 1881. Patient twenty-one years old, single. Recovery. Many pounds of ascitic fluid removed. The stomach was dilated and distended with fluid. Owing to the presence of lymph and adhesions, the liver and spleen could not be seen nor felt. Much lymph covered the peritoneum and was in the shape of flakes and masses and layers upon the abdominal viscera. Tubercular deposits were seen on the bowels. The disease was tubercular peritonitis. The patient went home at the end of three weeks. I have heard from her at various times, through the kindness of Dr. Tower, of South Weymouth, whose letter of November 21st is appended. The discharge of ascitic fluid through an opening in the wound gives the patient much relief.

SOUTH WEYMOUTH, Mass., November 21, 1884.  
DEAR DOCTOR HOMANS,—I am happy to say that M. is as comfortable as we could reasonably expect a woman to be who has had an exploratory incision through the wall of the abdomen, leaving a fistulous opening from which there is a serous (or sero-purulent) discharge more or less profuse continually kept up. She has gained considerable flesh, so that she looks in her countenance much improved. The appetite is generally good. Bowels inclined to constipation but kept open by aperients and laxatives. Recently she complained of acute pain in the left iliac region, and later in the right iliac region. I attributed this to distention of the intestine from flatus, and prescribed accordingly with relief of the pain. As there is inflammation of the peritoneal covering of the bowels, we can hardly expect she will be entirely devoid of pain, although I suppose tuberculous inflammation (being of a chronic character) is less likely to be attended with pain than acute inflammation. The pulse is eighty or under, rather small and weak. Tongue less red and tender than three months ago but not yet normal. She is of course in invalid, but within certain limits may be regarded as comfortable. She walks out short distances when the weather is pleasant. The fact is demonstrated, in her case, that a woman with tubercular peritonitis not only survives the operation of abdominal section but thereby has been relieved of the dropsical accumulation in the peritoneal cavity which otherwise would have existed. Possibly her life is prolonged by the surgical interference, although it may be an open question, not yet capable of solution, whether ascites with occasional paracentesis for its relief would have been attended with as much comfort and longevity. I think, however, that having survived the perils of the operation, her condition is now much better than it would have been without the operation. C. C. T.

## SIMPLE EXPLORATORY INCISIONS.

No.	Date.	Place of Operation.	Condition.	Age.	Anti-septic?	Result.	Remarks.
1	December 18, 1878.	Stoneham.	W.	62	Yes.	Recovery.	Ascitic fluid never reaccumulated.
2	February 22, 1881.	Boston.	W.	48	Yes.	Recovery.	Much ascitic fluid. A burst pyogenic cyst attached to pubes, ischiun, rectum, and pelvic organs generally. Died, September, 1882.
3	September 22, 1881.	Boston.	M.	21	Yes.	Recovery.	Ascitic fluid removed. Many thin-walled, delicate, bluish-colored cysts attached to the peritoneum and intestines. A friable, humerous tumor in right side of pelvis. Patient reported as perfectly well in December, 1881.
4	August 18, 1881.	Boston.	M.	36	Yes.	Recovery.	A small amount of ascitic fluid. Tumor a sarcoma, but so adherent that its origin could not be determined.
5	August 21, 1882.	Boston.	S.	39	Yes.	Death.	Tumor probably originated in the left ovary, and was inseparable from the intestines, even at the autopsy.
6	September 20, 1882.	Boston.	S.	37	Yes.	Recovery.	Large malignant tumors of omentum, liver, intestinal organs, and ovaries. Died six months later.
7	May 8, 1883.	Boston.	S.	31	Yes.	Recovery.	Tumor inseparable from intestines and peritoneum; probably malignant.
8	August 7, 1883.	Boston.	M.	60	Yes.	Death.	Thirty pounds of ascitic fluid. Abdominal and pelvic organs, as far as seen, more or less covered with nodules of cancer.
9	March 22, 1881.	Newton.	W.	66	Yes.	Recovery.	Large tumor of omentum and abdominal organs generally. Pelvic organs shut off by lymph.
10	June 13, 1881.	Boston.	S.	17	Yes.	Death.	Original disease probably pyo-salpinx.
11	June 19, 1881.	Boston.	S.	21	Yes.	Recovery.	Ten pounds of ascitic fluid. Tubercular peritonitis. Quite comfortable and much improved in December, 1881. A permanent opening in the scar, through which the peritoneal fluid escapes, and thus prevents accumulation and pressure.

It will be seen that simple exploratory incision in a patient who is not too feeble, followed by gentle manual exploration, is usually innocuous and sometimes beneficial, as in case I., where the ascitic fluid never reaccumulated. Case III., where the tumor is reported to have disappeared, and the patient's health to be re-established, and case XI., where the patient has gained flesh and strength.

Four exploratory incisions were followed by emptying of the cysts in three instances, and the removal of a few small masses in the fourth.

Patient thirty-six years old, married. Recovery, December 29, 1881. On opening the abdomen a large cyst of a bluish color and vascular look presented; this was tapped, and fourteen pounds of fluid removed. An interior cyst was also emptied. On the exterior of the tumor was a kidney-shaped mass about three inches long; this was burnt off with Paquelin's cautery and the base tied. The tumor was a multiple fibro-cyst of the uterus. The opening in the cyst-wall was sewed up with catgut. The patient recovered promptly and went home at the end of three weeks. The fluid gradually reaccumulated and the patient died about two years later. Hysterectomy would have been the proper operation, but neither the woman nor her husband desired the performance of a dangerous operation.

Patient forty-two years old, married. Death, May 6, 1882. When the peritoneum was opened forty pounds of ascitic fluid ran out. A cystic tumor filled the pelvis and prevented me from getting my hand below it either in front or behind. Several small cysts in various parts of the tumor were punctured, and afterward carefully sponged out and sewed up. The wound was closed as usual. The patient died on the fourth day. There was no autopsy.

Patient thirty years old, married. Death, April 21, 1883. About twenty pounds of ascitic fluid were removed. Papillomatous cystic tumors in the broad ligaments, and masses on the peritoneum everywhere were scattered about. More or less of the masses were removed, but it was found

impracticable to remove many or all of them and the operation was abandoned and the wound closed. The growths were not especially ovarian, though they probably originated as such. The patient died suddenly on the third day; there was no autopsy.

Patient fifty-four years old, married. Death, October 18, 1884. On incision the peritoneum was found to be a quarter of an inch thick. On cutting through this membrane a viscid tenacious fluid looking like thick mucilage ran out. On inserting the hand it was found that the anterior wall of of the cyst had become incorporated with the peritoneum and the posterior wall had been perforated by a tapping done at her home, or else had burst. A hardish-feeling tumor filled the pelvis and was covered with a pinkish-colored roughness. About twenty-five pounds of thick gelatinous fluid ran out of the abdominal cavity. Deposits of cancer were seen and felt in the bowels and probably were disseminated throughout the abdominal organs. Another cyst filled with the same kind of fluid was found attached to the lumbar vertebra; it was punctured, emptied as thoroughly as possible, and a glass drainage tube was put in it. The abdominal cavity was thoroughly sponged out and the wound closed around the drainage tube. No definite outline of the uterus or ovaries could be made out. At the close of the operation the patient's condition was excellent. She died rather unexpectedly the next day. There was no autopsy.

It will be noticed from the foregoing account that interference with an abdominal tumor without completing the removal of the growth is exceedingly dangerous. And it will grow more dangerous until we reach the class of cases when we say we have *left behind* portions of the tumor, instead of saying that we have *removed* a portion; that is, in the former class a great deal more has been removed than has been left and in the latter a great deal more has been left than has been removed. I hope to continue an account of the other miscellaneous operations at some future meeting of the Society.

## EXPLORATORY INCISIONS WHERE THE ABDOMINAL TUMORS WERE SLIGHTLY INTERFERED WITH.

No.	Date.	Place of Operation.	Condition.	Age.	Anti-septic?	Result.	Remarks.
1	December 29, 1881.	Boston.	M.	36	Yes.	Recovery.	A large uterine fibro-cyst was emptied of fourteen pounds of fluid, and a fibroid tumor about three inches long was removed from the exterior of the cyst. Patient died two years later. The proper operation would have been hysterectomy.
2	May 6, 1882.	Boston.	M.	42	Yes.	Death.	Died on third day. Several cysts were punctured. Tumor apparently uterine, and generally adherent. Forty pounds of ascitic fluid removed.
3	April 21, 1883.	Boston.	M.	30	Yes.	Death.	General papilloma, that is, general abdominal cancer. Died on the third day.
4	October 18, 1884.	Boston.	M.	54	Yes.	Death.	Thirty pounds of fluid, looking like vaseline, removed. Some cysts punctured and removed. Drainage. Death on second day.

# INVERSE TYPE OF TEMPERATURE IN TYPHOID FEVER, WITH A REPORT OF TWO CASES.<sup>1</sup>

TEMPERATURE PECULIARITIES IN EPIDEMICS, WITH A REPORT OF SEVEN CASES IN ONE FAMILY.

BY W. C. HOLLOPETER, M.D.

THE classical investigations of Wunderlich, Thierfelder, and Traube, have done much to simplify the study of fever, and by their deductions they have rendered it possible for us to differentiate typhoid from all the other continued fevers by its temperature alone. This universal tendency to refer a given symptom to an established, or partially established, law has done much to lessen the interest of individual work; for those cases marking the exception are, as a rule, looked upon as complications, and slight causes are frequently brought forward to explain the apparent departure from the established rule. Dr. J. C. Wilson, in his admirably written work on "The Continued Fevers," tell us that "marked deviations from the typical course of the temperature are always due to special causes. These causes, in many cases, cannot be discovered by the most searching investigation. On the other hand, upon inquiry, clinical facts of importance are often discovered, and it is therefore the duty of the physician, in every case when marked deviations occur, to make diligent search for their cause."

I enunciate a well-recognized fact when I state that every physician in general practice has had cases of typhoid fever where the temperature record has been irregular, when, at the morning or the evening visits, the thermometer has registered the same, or has shown some unusual features in the evening exacerbation, or morning remission, departing in some unsatisfactory manner from the gracefully arched curve of Wunderlich.

It has frequently been my lot to treat cases of fever having every symptom of typhoid, yet not responding to the well-marked type of temperature, as described by Wunderlich. For a long time it was very difficult to assign any cause for the variation, although it is natural for complications to disturb the rule, especially when we anticipate a typical curve in the temperature chart.

Dr. William Pepper has stated, in a recent clinical lecture, that "it was the exception, and not the rule, to find a typical case of typhoid fever." Although every symptom may be uncertain, or even frequently wanting, in some cases of typhoid fever, yet I believe the temperature, the peculiar form especially, remains the most constant factor, and, as Griesinger states, it "generally controls the situation."

During the last seven months I have had under my care a case of typhoid fever, in which the temperature record corresponded to the "inverse type," as described by Traube.

Bäumler, in drawing attention to this unusual character of the temperature, states that, in the great majority of cases, the daily fluctuations follow the rule of health, the exacerbation taking place in the

evening. We sometimes meet with cases where this order is reversed, the rise taking place in the morning, and the remission occurring in the evening.

This "inverse type," so named by Traube, of the daily fluctuations of a febrile temperature has been observed in some rare instances in typhoid fever.

I have been unable to find any additional reference to this unusual type of temperature in the systematic treatises on fever. Liebermeister or Murchison do not mention it in their works, nor have I been able to find any clinical reports bearing on the subject in any of the medical journals.

The clinical notes of my case are as follows:—

Frank M., aged fourteen, of thoroughly healthy parents, was taken ill, May 15, 1884. My friend, Dr. Schoales, being the family physician, was sent for. The doctor was indisposed at the time, and I was requested to take charge of the patient. I found that the boy had been sick for two days, a slight chill occurring three days previous, and ever since he had been feverish, restless, and stupid; he had refused food, and complained of headache; he had also slight nose-bleed and loose bowels. The history of the case was not unusual, having every well-marked typhoid symptom, and was of interest in the character of the temperature alone, which was as follows:—

Date.	A.M.	P.M.	Pulse.
May 15 . . . . .	102.88	102.9	100
May 16 . . . . .	104	103.4	108
May 17 . . . . .	103.5	103	108
May 18 . . . . .	103.8	102.4	112
May 19 . . . . .	105.4	104	116
May 20 . . . . .	104.6	101.4	96
May 21 . . . . .	105.6	102.8	108
May 22 . . . . .	100	102.2	96
May 23 . . . . .	99.8	99	96
May 24 . . . . .	100.8	100	96
May 25 . . . . .	101.6	101	96
May 26 . . . . .	101.8	101	100
May 27 . . . . .	98.8	99.2	100
May 28 . . . . .	100	101.4	100
May 29 . . . . .	100.2	99	100
May 30 . . . . .	101.6	99	98
May 31 . . . . .	101	97.4	98
June 1 . . . . .	100.8	99	100
June 2 . . . . .	98	98.4	98
June 3 . . . . .	98.4	97.4	98

In this case the boy had been complaining for a few days, according to the statement of the parents, before advice was called in. How much longer he had been ill we are unable to state, but, judging from the elevation of the first temperature (102.8°), the case was evidently well on in the first week.

The exacerbation recurring so regularly in the morning, and the remission taking place as faithfully in the evening, caused me to watch the case with unusual vigilance. We could hardly be mistaken in the character of the fever—Dr. Schoales subsequently visiting the case with me frequently, and corroborating the diagnosis; the stupid and listless countenance, the distended and tympanitic abdomen, the rose-colored spots, few, but constant throughout the illness, the gurgling in the lower portion of the abdomen, the loose bowels, the nose-bleed, the deafness, all conjoined to render the diagnosis certain. Then the duration of the illness,

<sup>1</sup> Read before the Philadelphia County Medical Society, November 26, 1884.

while not very severe, extended over four weeks, which corresponds to the average duration of uncomplicated typhoid fever.

The treatment of the case was such as to have but little effect on the temperature, except to lower it; diet exclusively of milk and milk food; the recumbent position faithfully maintained; large and well-ventilated room, thoroughly disinfected. No drug was used likely to influence the fever, with the exception that, during the prevalence of the highest records, thirty grains of quinine sulphatis were exhibited in ten-grain doses two hours apart during the night. This was ordered on three successive evening visits. Cold-water sponging of the body was continued frequently as long as the temperature remained above  $102^{\circ}$ . We were unable to discover any complications whatever; in fact, there were none; no bronchial irritation, no disturbance of the alimentary tract. The course of the fever was so uniformly regular, the various symptoms occurring in their usual order, and the whole phenomena of the fever convincing as to its character, except the very important factor noticed in the *inverse type* of temperature.

The want of uniformity in the temperature record of the case just noticed recalls the facts in a patient I had under my care nearly three years ago. The clinical notes recorded on the back of my temperature sheet at the time are briefly as follows:—

Walter, aged seven, was a well-developed boy, and the youngest in an exceedingly healthy family. The mother informed me that the boy had commenced to manifest a disinclination for food and play five days before any trouble was suspected. I was therefore called in on the evening of the fifth day. I found the little fellow quite delirious, with a temperature of  $103.1^{\circ}$ , a full pulse of 130, respirations 26, face flushed and apparently swollen, eyes congested, skin dry and hot, bowels confined. Ordered a fever mixture.

In the morning the temperature had fallen to  $100.2^{\circ}$ , pulse 100. The patient had relapsed into a quiet sleep during the early morning hours. The skin had become moist. On a more careful examination I found the abdomen tender, somewhat tympanitic and distended. The mother stated that there had been, during the past ten days, occasionally slight nose-bleed. The bowels showed a disposition to be free, yet, while not constipated, they had not been open regularly every day, now one or more free movements occurred daily. The third day, and probably of first week, if not more, the temperature, with a single exception, did not go above  $102^{\circ}$ , but had a gradual decline. The interesting feature was the morning record, which was higher than the evening. This unusual feature continued for twelve days; the amount of variation was from one to one and a half degrees.

On the twelfth day, about the twentieth of the attack, the morning temperature reached  $103^{\circ}$ , without any other unusual symptom, after which it changed and ran as a typical case of typhoid fever in convalescence: morning  $100^{\circ}$ , evening  $102^{\circ}$ ; morning  $98.8^{\circ}$ , evening  $101.1^{\circ}$ , etc.

The downward curve was thus continuing uninterrupted until the seventeenth day, when the temperature ran up to  $102^{\circ}$  again; following this rise,

the morning record marked  $98^{\circ}$ , and an intestinal hæmorrhage of over four ounces of dark blood, following an unusually large fecal movement.

The thermometer never registered a temperature after this above  $100^{\circ}$ . The case made a good recovery, convalescence slow. In this case we had a temperature-curve closely following an ordinary typhoid-fever chart, with the unusual exception of the twelve days of *inverse type*, with no discoverable complications to explain the cause.

I have not deemed it expedient to enter into an accurate analysis of each and every symptom of the foregoing irregular cases, knowing it to be exceedingly burdensome, yet I hope that I have sufficiently outlined the general features of typhoid, the phenomena of which are so constant as to make a diagnosis practically certain.

I wish now to present the salient points in a group of seven cases, occurring in the form of an epidemic in one family, in which the victims followed each other to bed in rapid succession, four of whom suffered very severe and prolonged relapses. All, however, eventually made a good recovery. It is not my intention to narrate these cases as especially unique or exceptional, but as taking place under one roof, and springing from one well-recognized cause; the variation in the temperature record alone became an interesting element of study.

The fever occurred in a very healthy German family; the parents as well as the children were free from any predisposing weakness.

CASE I.—Mary, aged thirteen, was the first to take sick. I made my first visit to her on December 6th, when I obtained the following history: The patient had been complaining for nearly a week of weariness, chilliness, aching in limbs, back, and head, loss of appetite, and a general disinclination to any physical exertion. I found her, at 12 M., with a temperature of  $101.8^{\circ}$ , pulse 112, skin hot and dry, puffiness around the eyes, with an injected conjunctiva, face dark and flushed. During the day had diarrhœa, with vomiting. At 8 P.M. of the same day, vomiting (continuing) of thick, tenacious mucus, tinged with blood and bile; bowels were opened seven times during the afternoon. Since my morning visit the girl had had low muttering delirium, but can be aroused by speaking in a loud voice. The backache was so very severe as to merit especial mention, it being more pronounced than is usually found in bad cases of typhoid. The girl constantly complained of it during the first ten days. On the same evening at 9 P.M. the thermometer had registered  $105.8^{\circ}$ . In the morning it was  $101.8^{\circ}$ ; in the evening it was  $105^{\circ}$ . During the day and night vomiting and purging continued nearly hourly—fifteen times by the nurse's report.

At the end of the eighth day, the second day of my visiting, the backache continued violently, the hands being involuntarily placed in that region. Bowels continued loose, vomiting the same. Distention and tenderness of the abdomen decidedly marked, with gurgling in right iliac fossa, tongue heavily coated, dark, and foul, sordes on teeth and lips. Vomiting discontinued on third day after taking her bed. Temperature  $101.8^{\circ}$  in morning,  $105^{\circ}$  in the evening; low muttering delirium, alternating with violent outbursts; three or four well-

defined, rose-colored spots at this date made their appearance on the abdomen. After the fourth day, probably the tenth or twelfth day of her sickness, the temperature did not run higher than  $101.6^{\circ}$ , but did not fall below  $102^{\circ}$  until the eighteenth day. One very noticeable feature in this severe case was that, for two weeks, every other morning's fall was less or intermittent in character, while the evening exacerbation remained the same. During this period there existed the wildest delirium, it being difficult at times to retain her in bed; bowels frequently moved involuntarily. The girl gained her strength very slowly; it was five weeks before the temperature approached normal, and it was ten weeks before she was able to leave her bed. She however made a good recovery.

The point worthy of attention is that the temperature in this nearly fatal case remained nearly the same for the morning and the evening record. Lummernan tells us that only in cases in which the fever is very severe, and the absolute temperature very high, that the difference is less, and does not exceed three fourths of a degree.

CASE II. — The second member of the family to fall ill was the mother, aged thirty-two, who had acted as constant nurse to the daughter. It was thirty-four days after the daughter was taken sick, and the daughter was yet in bed, that the mother was compelled to relinquish her duties. I might state that the mother was on the eve of her confinement, that she watched and waited on her sick child up to the hour of her illness, she passed safely through her labor, remained in bed one week, was up and around the house for *five days* before she had any decided symptoms of fever. She had a slight chill which was soon followed by a temperature of  $104.6^{\circ}$  in the evening. This was, however, the highest point reached. She had no delirium or vomiting. Bowels were opened daily, but not unnatural. The temperature remained high for over a week, ranging between  $103^{\circ}$  and  $104.5^{\circ}$ . It had a gradual decline for over thirty-six days, when it reached normal, without any unusual variations between the morning and evening record. Convalescence was very slow. The record was a typical temperature record from the second week of typhoid, yet much milder than the child. The puerperal state did not seem to modify the course of the fever or endanger the life of the patient.

CASE III. — The husband and father, aged thirty-six, a house-carpenter by trade, a rugged and compactly-built German, was next on the list. He was a perfect type of physical perfection. He continued his work up to the hour of taking his bed, on February 10th. He had complained of a cold, headache, and sore throat for two days previously. I found him, on the morning of the tenth, with a temperature of  $105.6^{\circ}$ ; pulse 90; respirations 20; dry, hot skin; dark and infected countenance; bowels loose; abdomen flat; very stupid and sleepy. In this case the pulse was full and regular, never going above 90, yet for over two weeks his temperature lingered around  $105^{\circ}$ , with profound stupor, alternating in the wildest delirium. He had, during the second week, constant *subcutaneous tenderness* and frequent involuntary movement of the bowels. On the twenty-second day of his illness he suffered a hæmorrhage

of fully eight ounces. He had several smaller hæmorrhages previous to this date. On the sixteenth day his temperature fell to  $101.2^{\circ}$ , remaining under  $102^{\circ}$  with but one exception, when it ran up to  $103^{\circ}$ . Temperature did not reach normal until the thirty-eighth day.

CASE IV. — Caroline, aged five, was taken ill on January 13th, three days after her mother. She started with a temperature of  $104.6^{\circ}$ . She had been listless and stupid for a week preceding her complete prostration; during the prodromata I registered her temperature twice daily, but did not find the thermometer above  $100^{\circ}$ . Two days from the last date, the fever had reached  $105.4^{\circ}$ . From this point on it was a gradual decline for twelve days, when it as gradually climbed up to its old figure of  $105.4^{\circ}$ . This intermittent type continued for forty-two days, when it fell below  $100^{\circ}$ , and I ceased to make a record. The case was one of unusual severity, frequently losing large quantities of blood by the bowel, yet constipation was the rule throughout the illness. Epistaxis was also constant, the face being stained daily with blood; low delirium existed for over two weeks. The patient was in bed for over seven weeks.

CASE V. — Katie, aged ten, had a temperature record of her own — a marked difference existing in this case from the others. Above  $104.4^{\circ}$  to start with, reaching  $105^{\circ}$  the same evening, remaining above  $104^{\circ}$  for *three days*, then gradually declining for three days, when it again assumed the upward tendency, holding it for three days; then came a rapid fall. This intermittent character in the temperature continued for thirty-two days. This case was obstinately constipated throughout her illness, and was but slightly delirious. Recovery slow. Six weeks in bed.

CASE VI. — Pauline, aged fourteen, an unusually well-developed girl, and the last case which I deem of sufficient interest to record in the history of this family epidemic, will also illustrate a different phase in temperature irregularities. Three of the children before they became actually sick were noticed to have a weary, listless expression, did not manifest interest in their play, showed a decided preference for the house, which was contrary to their usual habits.

I registered the temperature of two of the younger children for a week or more before they were stricken down, and I did not find an elevation of temperature but slightly above normal, unless the temperature was taken in the evening, when it was generally near  $100^{\circ}$ . Taking into consideration the daily fluctuation in health, which is always higher in the evening, I could scarcely draw the line between the normal evening elevation in health, and the insidious approach of the fever. With Pauline I still endeavored to anticipate the onset of the disease. Acting on the suggestion of some of my professional friends, I commenced to register her temperature nearly two weeks before I perceived any indications of her being the next to fall sick. I might anticipate any theoretical conclusions likely to find lodgment in your minds as to the causation, by stating that the girl had been employed in a dry-goods store, and was brought home to take charge of the sick family. Upon her devoted

most of the washing and cooking for the sick. While the younger children were out of the house nearly all day at play, she was busy with household duties, and was in this way more exposed to the infectious disease than her younger sisters, who seemed to contract it so readily. I found it most convenient to take her temperature at the time I visited the other members of the family, that is, between nine and eleven in the morning, and eight and nine in the evening. I never found her temperature above normal, until within four days before she was compelled to take her bed. Three days before her prostration, the thermometer registered  $102^{\circ}$ ; normal the following day; second day it was  $101.6^{\circ}$ ; the following day it ran up until it reached  $104.4^{\circ}$ . Her temperature continued high for over ten days, ranging from  $103^{\circ}$  to  $105^{\circ}$ ; then assumed the intermittent character so frequently noticed in the record of the other members of this family, after which the fever record had a gradual decline. By anticipating her attack of the fever, and registering her temperature for over a week, three days in which her fever was above normal, gave us part of the ascending scale of Wunderlich — yet does not supply the gradual ascent and the lengthened arc of the semicircle, which should describe the model typhoid temperature record.

I have hinted that the cause of this epidemic had a tangible existence. While it is not the object of this paper to touch upon the aetiology of typhoid, yet it may not be without interest to mention the environments of this fated household. It is unusual to have seven cases of typhoid occur in one family, and follow each other in such rapid succession; yet not until the third member of the family was prostrated, could an adequate cause be found.

The head of the family was an industrious carpenter, who resided, with his wife and five children (two older girls were not living at home), in a two-storied, four-roomed house, near Thirteenth and Columbia Avenues. The house was quite comfortable for a small family, but not so for this one; hence they were crowded. Yet I have seen families packed in, and live free from disease, when there has been actually more to a room than in this family. The cellar was dry, drainage in a fair condition. A vacant lot of enclosed ground intervened between our family and the nearest neighbor on the north. This neighbor on the north was in the milk business, and for his convenience he had excavated a pit in the vacant lot adjoining our family's cellar wall, four feet deep, into which he had dumped the rubbish of the yard. The rain and snow, falling upon the decomposing mass of organic material, soon found its way through the intervening stone-wall; percolated its liquid poison into the cellar. This filth, while not at all times sufficient to be recognized by the sight, was more frequently perceptible to the sense of smell. The pit could in no way impregnate the drinking-water of the family for, as a precaution, I had all the water that was consumed for that purpose brought to them from a distant neighbor.

While we have mentioned the exceptional in the temperature record, we may also entertain a doubt of this rubbish pit being the only factor in the family illness. The first case in the epidemic,

Mary, aged thirteen, was employed in a store; hence she was not in the atmosphere of the house as long as the mother, who was the only one who constantly lived in the poisoned house, and yet second on the list, and, while she had a severe attack, her illness was not so prolonged as the first. Again, Pauline, the eldest girl, came from another family, in perfect health, resided for three months in the infected house, exposed to every form of contagion, and was the last to succumb to the disease; and when finally she was prostrated, the fever ran a comparatively mild course.

In directing your attention especially to the peculiarities of temperature in the foregoing cases that ended in recovery, I wish now to contrast them with one that, while the temperature was under control, and lower than any of the foregoing, yet, without complications, ended fatally.

A finely built young man of twenty-seven, regular, but rather full habit, first complained, on August 1st, of intense headache, backache, indifferent appetite, and general disinclination to exertion. He left the city, against the wishes of friends, as well as myself, for a trip through the South. On the third, he was taken violently sick; sent home, he reached the city on August 4th. At my first visit, same day, at 12 M., temperature was  $104^{\circ}$ ; at 8 P.M.,  $104.4^{\circ}$ . On the sixth day, he lost consciousness. His delirium was wild and pugnacious; constant mutterings. At the same time, his temperature fell below  $104^{\circ}$ , and remained below for over a week. On the tenth day his temperature reached  $101.6^{\circ}$ . From this point it fell, and remained under  $103^{\circ}$  until the fifteenth day, when it ran up to  $104.6^{\circ}$ , at death.

It is unusual to find patients unconscious when the temperature is so easily under control. In this patient the only antipyretic measure used was the cold bath. None of the symptoms of this case were as severe as the group occurring in the epidemic; yet this case terminated in death, while all of the others, indifferently nursed and badly surrounded, made good recoveries.

While it has been my principal object to record these cases of typhoid, as departing in a measure from the temperature law of Wunderlich, I wish to call your attention incidentally to the following facts:—

First, Six of the group of cases noticed in this paper were children, yet we had a severe course of the fever, and the temperature record commenced high, showing frequent irregularities. Wunderlich states, that in children, particularly in the younger subjects, the course of typhoid temperature is somewhat irregular. The commonest of these irregularities is its extreme mildness; yet the temperature rises in the first days to a higher average than in adults; it passes more quickly into the remitting period, and defervescence is less protracted, but complications often occur, closely indicated by the temperature.

Second, In the nine cases of typhoid, including mild as well as severe examples, we had four cases of intestinal hemorrhage; an unusually large percentage. Systematic writers on fever regard intestinal hemorrhage as a rare and grave symptom. While Liebermeister states that there is not a single

symptom belonging to typhoid which can be characterized as pathognomonic, yet a tendency to diarrhoea is quite frequent and intestinal hæmorrhage quite rare; in our cases we found the bowels confined in over half of the cases.

Dr. Broadbent looks upon constipation in typhoid as of sufficient importance as to entitle the fever a distinct variety.

## Hospital Practice and Clinical Hæmorrhæda.

### MASSACHUSETTS GENERAL HOSPITAL.

SERVICE OF GEORGE C. SHATTUCK, M.D.

### CASE OF ULCERATIVE ENDOCARDITIS.

REPORTED BY HENRY JACKSON, HOUSE OFFICER.

#### HISTORY TAKEN FROM THE FATHER OF THE PATIENT.

FAMILY history good. Child always delicate; subject to slight cough; he had noticed rapid and violent action of the heart. So far as the father knew the child had never had any acute disease.

Four days before entrance the child was apparently as well as usual. Three days before entrance she seemed sick in the morning; vomited once. That night was restless and had slight pain in her head. The next day screamed all day from severe pain in her head; the day before she entered she was delirious, constantly tossing, screaming, and apparently in great pain. She had not slept since the first of the attack.

*Physical Examination.*—Child twelve years old, emaciated, cold, and livid; mouth open; sordes on teeth and lips; tongue dry and cracked. Moans occasionally; head retracted; muscles of back of neck rigid; thighs flexed; resists attempt to straighten them. Lies on the left side and cries if touched. Very violent, tumultuous pulsation in the left front from second to fifth interspace. No localized apex beat. Thrill at the apex most marked in the sixth interspace just outside the nipple; area of cardiac dullness begins on the second rib, extends one and one-half inches outside the left nipple, and half an inch to the right of sternum. Loud presystolic and prolonged systolic murmur at the apex. Systolic murmur is transmitted into the left back. The pulmonary second sound is accentuated. Pulmonary resonance and vesicular respiration throughout the chest without rales. Pupils contracted, equal. Nothing abnormal was found in the abdomen. The spleen was not examined. There were a few small darkened papules on the trunk. Temperature 102 F.; pulse very small, 140; respiration, 35. In the afternoon patches of urticaria appeared on the legs and abdomen. Tracheal rale; morning; evening temperature 105.5 F. A little morphia was given at night. The next day numerous small petechiæ were found scattered over the body. There was involuntary micturition. The patient was perfectly quiet all the second day, and died at 1.30 p.m.

*Autopsy by Dr. R. H. Fitz.*—Extreme lividity of

the dependent portions of the body. Numerous small petechiæ and hæmorrhagic papules.

**Brain.** On removal of the calvarium the dura mater was tense; the pia mater was deeply injected and dry; the convolutions somewhat flattened; pale opaque gray streaks along the veins over the convexity, suggesting purulent infiltration. The right side of the brain near the angle over the fissure of Sylvius contained a diffused patch of hæmorrhage infiltrating the arachnoid, and extending to the median line at the base. Both middle cerebral arteries were obstructed by reddish-gray emboli at the point where the anterior cerebral arteries are given off.

In the cerebral substance of the right hemisphere, corresponding to the region supplied by the obstructed artery, was a clot of blood the size of a walnut, lying in a cavity the walls of which were dotted with points of blood.

**Heart.** Pericardium opaque and thickened. Heart the size of an adult's fist. The initial valve admitted two finger-tips. Endocardium of the left auricle and ventricle were thickened and opaque. Endocardium of the left auricle near the initial valve was spotted with numerous elevated patches of gray translucent tissue. A reddish-gray soft thrombus adhered to an ulcerated surface of the left auricle. The ulcer was as large as the end of the thumb. Curians and tendons of the initial valve were thickened and contracted. Spleen was increased threefold in size.

In the kidneys were numerous nodules of anæmic necrosis, several of which contained small cavities from which purulent fluid could be squeezed. There were also emboli of the liver and spleen.

**Diagnosis.** Cerebral embolism and hæmorrhage. Chronic endo- and pericarditis. Acute ulcerative endocarditis and parietal thrombosis. Embolism (septic?) of spleen, kidney, liver, and hepatic artery. Fatty degeneration of the kidneys.

## Therapeutic Hæmorrhæda.

### PHENOL-CAMPHOR.

BY THEOPHORE SCHARFEL, M.D., OF BEECHER, ILL.

The writer noticed (in December, 1882) the important fact that when common or Japan camphor and crystallized carbolic acid are mixed together and subjected to heat, a colorless liquid would be the result. The only reference he finds so far with regard to this reaction occurs in the very excellent and valuable scientific publication of Dr. E. R. Squibb, "Ephemeris of Materia Medica," etc., on page 673, vol. ii., No. 5, where a brief allusion appears under the appellation of Compound Alum Powder. Dr. E. R. Squibb, however, in a letter to the writer states that he has "several times before heard of this reaction between phenol and camphor." Phenol-camphor is best obtained by heating crystallized carbolic acid until it melts, and then gradually adding camphor; a clear liquid is obtained, which is characteristic on account of its permanency. In preparing this substance the writer uses equal parts of camphor and of carbolic acid. It remains liquid for an indefinite time, and does not solidify on being

subjected to the low temperature of a frigorific mixture of snow and sodium chloride. Phenol-camphor ( $C_8H_{11}O$  [?]) is a colorless, refractive liquid, possessing the fragrant odor of camphor, entirely extinguishing the one of carbolic acid, and has a sweetish camphoric, but biting taste, not as caustic as that of carbolic acid, somewhat benumbing the tongue. It is soluble in alcohol, ether, chloroform, and ethereal oils, but is insoluble in water, being heavier than the latter. I have not had the occasion to determine the boiling point and the specific gravity of phenol-camphor. When ignited it burns with a smoky flame. I have used phenol-camphor as a local anæsthetic in odontalgia, introducing it on cotton into the cavity of a carious tooth, with good success, and can speak of it favorably as a local anæsthetic in the ingrowing of the toenails.<sup>1</sup> This substance can be likewise used as an antiseptic. It mixes well with paraffin, cosmoline, and many oils. In impregnating cotton gauze (antiseptic gauze) phenol-camphor may be used as a substitute for carbolic acid. Phenol-camphor is less irritating, less caustic than carbolic acid, and has the advantage of possessing a pleasant odor.

## Reports of Societies.

### SUFFOLK DISTRICT MEDICAL SOCIETY.

ALBERT N. BLODGETT, M.D., SECRETARY.

#### SECTION FOR CLINICAL MEDICINE, PATHOLOGY, AND HYGIENE.

DECEMBER 10, 1884. The meeting was called to order at eight o'clock, P.M., by Dr. R. T. Edes, chairman.

Dr. H. I. Bowditch asked the privilege of addressing the Section for a few minutes, prior to the transaction of the business of the evening, and then spoke as follows:—

Before we enter upon the regular business of this Section, I ask permission to announce the death of one of the ablest of the members of the Massachusetts Medical Society. I allude to Henry A. Martin. He was, in my estimation, one of the strongest of the medical men it has been my fortune to meet either here or elsewhere. His long residence in Roxbury, and his frequent intercourse with the physicians and surgeons of Suffolk and Norfolk Counties, seems naturally to call upon us, who as a Section of the State Society meet first after his death, to take some notice of that event and of the loss which the profession has sustained.

Dr. Martin died of diabetes, quietly, and apparently without suffering, during the forenoon of December 7, 1884. He had been fully aware for two years that the disease had fastened upon him, but he made little or no complaint even to his family, but kept steadily at professional work until within a few past weeks. Finding that his strength was gradually but surely lessening, he had thought of resigning all laborious out-of-door practice and attending only to consultations at his office. During the last weeks especially, his physical debility

was greatly increased, and he kept his bed, but with no improvement.

Believing that death was near at hand he calmly bid farewell to his family, and soon after fell into a quiet sleep, from which he never awoke. Let us hope that such a tranquil ending of this life may be vouchsafed to us all.

In looking upon Dr. Martin's life and character, we must, I think, admit that in most of his salient points he was a man "*sui generis*." I at least know of no one like him. Intellectually he was far above most persons I have met, and physically he was one of the tallest and seemingly one of the most stalwart.

In conversation, not only on medical subjects, but upon a large range of topics, some of them widely removed from professional thought, he was superior to the majority of men. He had studied deeply into the history of medicine; in this department I know but one of our living associates who could approach him. He gloried in the greater heroes among the medical men of the past. Especially was he drawn to any one who by native vigor of intellect and perhaps fierce professional contests had won for himself fame in spite of all the babbling oppositions of men who apparently hated him because of his very superiority to themselves. For example, he sympathized heartily with that giant of our profession, grand old Ambrose Paré, who gained his ever-enduring fame in spite of the sneers of the robed professors of the School of Medicine at Paris, and the carping criticisms of smaller men in the profession at large. From a similar superiority of mind, and perhaps we may allow, from an apt readiness and joy in intellectual controversy, and from the fact that he never concealed an opinion even if it struck rather severely or perhaps sarcastically at even a friend's favorite notion, some have been led to think Dr. Martin was too pugnacious. Truth compels me to admit that at times he may have been almost savagely hypercritical in allusion to the writings or actions of others. Especially was this trait manifested whenever or wherever he knew there was a lack of fair dealing on the part of an opponent. But he was always a brave and frank-speaking antagonist. I have had some sharp passes with him at times, but our friendship was never marred by them. Nay more—I can say truly that my respect for him has always been rather increased than lessened by these contests, for I found him always open and fair in his opposition to my views. Anything like cant or hypocrisy or unfair dealing, exhibited by an opponent, seemed to awake in him a sort of fury, and he unsparingly used the lash upon his antagonist. With a kind of Martin Luther violence he would at such times hurl defiance at any thing or person that arose before him, and right manfully he would defend the position he had taken. I grieve to say that, in consequence of this peculiarity, some of the more sensitive of those whom he felt himself called upon to criticize may not hold his memory in their hearts so gratefully or so inspiringly as I do. I shall always regret his loss because our relations were always friendly, notwithstanding an occasional difference in opinion, and from him I could often gain excellent information which I could get from none else.

<sup>1</sup> I have also used it, in combination, in certain cutaneous eruptions due to cryptogamic cause.

Before closing these remarks, which have so much of a merely personal character. I would refer to the fact that, in addition to having been an able medical practitioner amongst us, he has been of inestimable advantage to every community in the world where animal vaccination is now used. His energy and decision of character, his knowledge of the past, have brought us all back to first principles on vaccination as proposed by Jenner.

One at least of his surgical devices is almost universally used, not only in this country, but in Europe, and probably elsewhere where surgery is practised.

For the above reasons we feel that he was an able practitioner of medicine and surgery for many years amongst us, and because medicine has been helped onward by his life's work, I have wished that due honor should be paid to the memory of our dead associate.

Believe me, gentlemen, you will wait for a long time before a man comparable with him will arise amongst you.

By motion of Dr. BLODGETT, seconded by Dr. J. P. REYNOLDS, Dr. Bowditch was requested to convey to the family of Dr. Martin the regrets of the Section at the loss of one of the distinguished members of the medical profession.

#### SACCHARATED OXIDE OF IRON.

Dr. G. L. WALTON exhibited a preparation of iron to which he had called attention some months ago in a published article, but which had not become generally known to the profession.

It may possibly be remembered that I called attention<sup>1</sup> sometime since to several agreeable iron preparations in common use in Germany, but not as yet introduced into America. The merits of one of these preparations especially impressed me, namely, the so-called *Eisenzucker* (*Ferrum Oxydatum Saccharatum Solubile*), and I am glad to be able to show a specimen of it this evening, and to state that Metcalf and Company have undertaken its preparation, with this very satisfactory result. It is a brownish-red powder, of a very agreeable, sweet taste, completely soluble in five parts of water, and containing three per cent. of metallic iron. It does not discolor the teeth, and on account of its ready solubility may be taken for an indefinite length of time without affecting the digestion, even in cases where iron is otherwise ill borne. It will be found especially valuable in chlorosis, for susceptible nervous patients, and for children. The dose is five to twenty grains three times a day, to be taken in water or in powder. Most convenient and agreeable will be found the tablets, of which I have here five and ten grain specimens. Mr. Davidson assures me that this particular sample contains three and one-half per cent. of iron by actual assay. He also tells me, it may not be out of place to state, that he finds the precautions given me by the Leipzig pharmacist, Herr Blaser, of the utmost importance, and that a much more satisfactory result is reached by following his directions (detailed in the article already alluded to) than by following simply those of the pharmacopoeia. The difficulty of making the preparation may have had something to do with the postponement of its intro-

duction in this country. Its value, however, once recognized, I feel sure it will be generally adopted, and it is rather remarkable that among the needlessly multiplied and unsatisfactory forms of iron in American pharmacy this really elegant preparation has been so long overlooked. To show that it is not identical with, and that it is far superior to, the saccharated carbonate of iron, I have brought in a specimen of the latter, which has very much the color and general appearance of dirt, and is not particularly agreeable to the taste. I pass around two bottles containing about five grains each of the powders and half an ounce of water. It will be seen that, while the *Eisenzucker* makes a perfectly clear red solution, the carbonate is only partially dissolved, giving a murky mixture with a black residue. (Dr. Edes asked for the composition, saying that it could hardly be an oxide if soluble in water.) In answer to Dr. Edes: I cannot find that the chemical formula has been made out. It is certainly more than doubtful if it is really an oxide, notwithstanding its name. It is mentioned in the United States Dispensatory under *Ferri Peroxidum Hydratum* as a so-called oxide of iron adopted in the German pharmacopoeia. The process of manufacture was then described briefly.

In answer to Dr. Webber, Dr. Walton said that he did not know how long the solution in water remained unchanged, but that it did so for several days he could state with certainty from observation.

Dr. J. J. PUTNAM then presented the first paper of the evening, entitled

#### A STUDY OF THE DEVELOPMENTAL DISEASES OF THE NERVOUS SYSTEM,

which is reserved for publication.

Dr. P. C. KAPP presented a very complete and exhaustive study of

#### CUTANEOUS AND DEEP REFLEXES,

extending over a long time and comprising several hundred observations, an abstract of which is here given:—

The observations were made upon 239 patients in the nervous and renal service at the Boston City Hospital.

The frequency of absence of the cutaneous reflexes was follows:—

	Cases Examined.	Present.	Absent.
Plantar . . . . .	234	217	17
Cremaster . . . . .	167	146	21
Clitell . . . . .	179	113	66
Abdominal . . . . .	239	192	47
Epigastric . . . . .	239	97	142
Erector spinæ . . . . .	178	45	133
Scapular . . . . .	177	13	162

In nearly every case in which the plantar and cremaster reflexes were absent there was either some lesion of the reflex arc, as in neuritis or myelitis, or some cerebral disturbance like coma, hemiplegia, or convulsions. No pathological cause could be assigned for the absence of the other reflexes. When the reflexes differed on the two sides it was usually significant of some unilateral disturbance of the

<sup>1</sup> Boston Med. and Surg. Journal, January 12, 1882.

nervous system, but in one or two cases no such disturbance could be made out.

The frequency of absence of the deep reflexes was as follows:—

	Cases Examined.	Present.	Absent.
Patellar . . . . .	239	192	47
Tibial . . . . .	231	18	213
Ankle clonus . . . . .	238	12	226
Toe clonus . . . . .	239	0	239
Triceps . . . . .	239	138	41
Radial . . . . .	239	131	108
Ulnar . . . . .	239	61	178
Extensors of wrist . . . . .	239	25	214
Wrist clonus . . . . .	239	0	239
Costal . . . . .	234	161	73
Lumbar fascia . . . . .	178	33	145
Spine of scapula . . . . .	178	45	133

The patellar reflex was also tested in eighteen patients under ether, and was found absent in six.

The patellar reflex was found absent not only in cases of myelitis, locomotor ataxia, multiple neuritis, etc., where there was evidence of lesion of the reflex arc, but also in many cases of cerebral disturbance, like coma, cerebral hemorrhage, and obscure cerebral disease, especially in alcoholic subjects. The theory was advanced that such disturbances in the brain might have an inhibitory action upon the reflex centres in the cord, abolishing their action.

The tibial reflex was found usually in cases where the patellar reflex was exaggerated, but was not necessarily pathological.

Ankle clonus was found four times immediately after convulsions; in other cases there was disease of the lateral columns. Its presence was regarded as always pathological.

In a few cases of exaggerated patellar reflex patellar clonus was tested, and was found in five cases, in four of which there was disease of the lateral columns. It was regarded as pathological.

The presence of the reflexes of the upper extremity was found to be very common. The cause of absence was not clear.

The costal cartilage reflex was found very often, and no clear relation between its presence and the existence of phthisis was apparent. The other reflexes were unimportant.

A difference of the deep reflexes on the two sides was usually significant of unilateral nervous disturbance, but, as with the cutaneous reflexes, one or two cases were found where no such disturbance could be made out.

Dr. WEBBER said that it gave him pleasure to testify to the correctness of these observations, as they were made when Dr. Knapp was house officer, during Dr. Webber's term of service at the City Hospital. He was able to "control" many of Dr. Knapp's experiments, and was satisfied that they were thoroughly reliable. They constitute a valuable addition to our recorded knowledge upon the character of different reflexes under a great variety of conditions.

#### TENDON REFLEX AFTER FRACTURE OF THE PATELLA.

Dr. Walton also introduced a cast of a knee, which he felt sure would be of interest, not only from the rarity of the case, surgically consid-

ered, but also in connection with Dr. Knapp's paper. The cast was obtained (through the kindness of Dr. W. J. Otis) from a patient who was under treatment in the nervous Out-Patient Department of the Massachusetts General Hospital for another trouble, but who had an ununited fracture of the patella, with separation of the fragments measuring six inches when the knee was flexed, three and a quarter inches when extended. The only difficulty experienced in walking, by the way, was in going up and down stairs. The interesting point in connection with the subject was that, while no reflex could be obtained by striking below the knee, a distinct reflex followed the tap just above the upper fragment, the muscle being felt to contract, the patella fragment to be drawn up, and the skin over the joint to retract, although, of course, no motion of the foot followed.

Dr. EDES spoke of the varying results which will be obtained according as the blow is struck with a greater or less amount of force, and penetrates more or less deeply into the tissues. The study of the phenomena of the patella is very interesting. This reflex is entirely absent only in those cases in which the nervous centres may be supposed to be diseased.

Dr. PUTNAM moved that the report upon the recent epidemic of cholera in Paris, which the Secretary had been requested to prepare, be postponed to the next meeting. Adjourned at 10 o'clock.

### THE PHILADELPHIA COUNTY MEDICAL SOCIETY.

REPORTED BY G. BETTON MASSEY, M.D.

MEETING OF November 26, 1881. Dr. W. C. HOLLOPETER read a paper on the INVERSE TYPE OF TEMPERATURE IN TYPHOID FEVER.<sup>1</sup>

Dr. J. C. WILSON, in opening the discussion, said: The paper of Dr. Hollopeter is very interesting and suggestive. It touches upon or suggests almost every important clinical problem relating to this disease. Its free discussion would be impossible in one, or indeed in many evenings. Two or three points call for special consideration.

First, The typical temperature-curve, and its variations. The well-known course laid down by Wunderlich as a standard is met with perhaps less frequently than strongly marked variations. Nevertheless, a knowledge of that course is the key to the understanding of the variations from it. Wunderlich, after describing the course of the first four or five days, lays down the law that every case which does not conform to this temperature type is not typhoid fever. This dictum has been the source of manifold errors in diagnosis. No more fallacious statement could be made. Cases of undoubted typhoid fever constantly occur, in which the range of temperature fails to conform to the typical curve, not only in the beginning of the attack but throughout the whole course of the disease. In fact, cases sometimes occur, the nature of which is fully established by the complexus

<sup>1</sup> See pages 28-32.

of symptoms and the existence of local epidemics, in which the temperature remains throughout even *sub-febrile*. The singularly labile temperature in this disease, rising and falling, as it does, under very slight disturbing external influences, makes it a matter of surprise, not that the temperature is not always typical, but rather that it ever closely conforms to the type.

Second, The inversion of the diurnal range, of which Dr. Hollopeter has given two instances, is not common. I have seen cases of it, to which I will briefly refer. I am not aware that any adequate theory of this curious clinical phenomenon has yet been advanced.

Third, House epidemics. The second part of the paper, which considers the details of this curiously circumscribed and localized outbreak, is very interesting and important. It is by the study of such house epidemics that a true insight into the etiology of the disease is to be gained. I do not agree with the author of the paper, in ascribing the disease in the infected house to the percolation of waste-water, through the cellar-wall, from the adjoining premises. In order to establish this theory, it would be necessary to show, first, that such percolation, if capable of producing this disease, had not been going on for an indefinite time prior to the attack; and, second, that typhoid fever had existed in the neighbor's house, or at least that the dejecta of typhoid patients had been thrown into the pit from which the drainage into the cellar ran. These facts have not been shown. On the other hand, it appeared clear enough that the first case, the young woman who had come home sick from another house, had introduced the disease. An investigation of the house and neighborhood from which she came would doubtless shed light upon the subject. House epidemics are numerous in Philadelphia. Certain houses, however, seem to be the abiding-place of the infecting principle, seeing that cases occur in them from time to time during a series of years.

Dr. E. T. BATES. I agree particularly with the remarks relating to the contagion. Two cases recently seen by me illustrate this: a washerwoman took home the clothes of a typhoid-fever patient. Within a week, her two children drooped and became feverish. They were taken to the Children's Hospital and one died there with no autopsy; the other was taken home, where it died, and I made a post-mortem examination. The typical conditions were present. No other cause was known. I am also interested in what Dr. Wilson has said about alterations of temperature from slight causes. We notice the same thing in diseases of the liver, in which cases the thermal wave fluctuates with the injection of food. If we admit these causes, I think we can readily admit psychic influences in the same rôle.

In diagnosing typhoid fever, it is to be distinguished from malarial fever and catarrhal fever. Malarial fever is *sui generis*, and can be controlled in this latitude by quinine. I believe that malaria will modify the initial stages of typhoid fever. Thus one of the groups of cases called typho-malaria takes its name. Neglected malarial fevers form another group of so-called typho-malarial fever, which is not a disease *sui generis*.

I have seen many cases of mild typhoid fever—the so-called typhoid ambulatorius. Throughout, these cases have shown a temperature of 100°, not over 100°, but I would not make the diagnosis of typhoid fever if the temperature after the fifth day fell below 100° in the evening.

Catarrhal fever is characterized by peculiar weakness, with various catarrhal conditions of lungs and bowels. The temperature runs from 99° to 100°, and is at times almost normal. Such cases should be classed as catarrhal fever, and are very similar to the specific forms of influenza. They may be recognized by the fact that the temperature is very irregular, and it is impossible to control this feature by quinine. I think these are the cases which have often been confused with mild typhoid.

Dr. B. TRAUTMANN. Niemeyer speaks of inverse temperature in typhoid fever, and says that these cases end, generally, fatally. This seems to disagree with the statements made here to-night. I have at this time a case showing this curve, in which a hemorrhage of the bowels followed this morning.

Dr. KEVIN. I have also a case now under treatment showing inverse temperature.

Dr. ARTHUR V. MEIGS. With regard to the etiology, I do not think Dr. Wilson's position is well taken. In the face of the authority of Murchison, that typhoid fever may arise *de novo*, it seems to me hardly fair to assume the germ theory as proved, although the medical mind seems at present to be inclined in that direction. Typho-malarial fever has always seemed to me a bad name, for it misleads; it means, in its proper sense, a hybrid, both malarial disease and typhoid fever co-existing in the body at the same time.

Dr. W. A. EDWARDS. In the case of a young man under my care whose temperature presented the peculiarities spoken of, a diagnosis of double quotidian was made. On the eighth day, signs of typhoid fever set in, and lasted four weeks; then again there was a typical double quotidian. If the case had not been so diagnosed, it would have been put down as a case of typhoid fever with inverted temperature. This, with other cases, I published in the *Medical and Surgical Reporter*, November 17 and 21, 1883, and mention it to-night to call attention to the fact that all cases of inverted temperature in typhoid fever are not due to the typhoid entirely, but frequently to a complication, this complication occasionally being almost unrecognizable except for its effect on the temperature.

Dr. WILSON. A clear comprehension of the mode in which typhoid fever is propagated from previous cases, by means of a specific infecting principle, is of the utmost importance. Murchison, it is true, held that it might arise *de novo*. Nothing in the literature of the subject is more brilliant than that great author's advocacy of this view, but the student of the subject knows that it was asserted in Murchison's day with a vigor scarcely inferior to that with which it has been defended here, with more success. To Dr. Wilson Budd, of Bristol, is due the credit of showing that Murchison's view was untenable. To-day it is no longer entertained.

Dr. MEIGS. I did not pretend to deny that a single case of typhoid fever may be the focus from

which any number of others may arise. I merely contended that, in the face of Murchison's opinion that the disease may arise *de novo*, we should be careful how we assume as proved the germ theory.

DR. J. SOLIS COHEN. I do not rise to speak directly to the subject of the paper, as I do not see typhoid fever except in hospital practice. Many years' observation has convinced me that sudden rises of temperature in typhoid fever, as in other diseases, are often due to obstruction of the bowels even though diarrhoea may exist. A small dose of castor oil will usually quickly relieve the bowels and reduce the temperature. The ordinary milk diet is then to be modified by the addition of lime-water, or by substituting boiled milk for cold. My residents have for years had general instruction to pursue this plan without awaiting my daily visits.

The family epidemic recorded, reminds me of a similar one in a German family, the members of which were distributed to several hospitals, three of them coming under my own care. A marked local epidemic occurred among the sailors on board the Russian war-vessels which, several years ago, were lying off the wharf at Kensington, some sixty of whom came under my care, with the most typical demonstration of the true typhoid curves that I have ever seen. The temperature charts looked as though they might have been copied from a textbook. The cause, in these instances, was the drinking of water from the Delaware River, which the sailors, following an old custom, dipped from the side of the vessel within a few feet of the open outlets to sewers.

I was very much interested in the story of the poor washerwoman's family. Our duty in the presence of contagious disease is very clear, and is too much neglected by physicians. We should not allow our patients to send clothes out to be washed, until they have been thoroughly disinfected. Indeed, rather than subject a family to contagion, let the clothes be burned. Many a poor washerwoman in this city brings typhoid fever, diphtheria, and other diseases, to her household, through the carelessness or indifference of her customers.

DR. HOLLOPETER, in closing the discussion, said: I had felt a certain uneasiness in presenting my cases of *inverse temperature*, as I could obtain but little authority for the same, yet I have recorded the simple facts, and am glad to learn that other members have also noticed similar cases. In a future paper I hope to give more of the literature of the subject. In answer to Dr. Wilson, as to the causation of the house epidemic, I would state that Mary, the first to take sick, was, at the time, not living at home, yet she frequently came home for a few days at a time. The family she was working in were all healthy.

—According to *The Dartmouth*, Dr. O. S. Taylor, of the class of 1892 of that college, living at Auburn, N. Y., completed his 100th year on December 17th. He also graduated from the Medical College in 1813, the second class that went out from that institution. As far as is known, he is the oldest living graduate of any American college.

## CHICAGO GYNÆCOLOGICAL SOCIETY.

W. W. JAGGARD, M.D., SECRETARY.

REGULAR MEETING, December 19, 1884. The President, DR. H. P. MERRIAM, in the chair.

DR. W. H. BYFORD read a paper entitled

### A CASE OF MURAL PREGNANCY.

The history of the case was obscure. The patient, twenty-eight years old, married seven years, had one child six years old. She supposed she became pregnant for the second time in February, 1883. In April she became fatigued, and had hemorrhage, which continued until May 9th.—about four weeks. On October 14th a discharge of yellow fluid, about one gallon in quantity, occurred. A putrescent, sero-sanguineous discharge followed, continuing three months. In January, 1884, a large brownish mass, with very fetid odor, was expelled. After this event menstruation occurred until July. In May she was quite large, and had bearing-down pains. She entered the hospital on October 6, 1884. She was tapped, October 18th, and about four quarts of thick, tenacious fluid, resembling the fluid of an ovarian cyst, were removed. This fluid coagulated, on the addition of nitric acid, and on boiling. Assisted by Dr. R. Filley, a microscopical examination was made, with negative results. The "Dresdale" cell was not found. Laparotomy was performed, and a fetus with placenta was removed without hemorrhage or difficulty. In order to secure perfect drainage, it was considered best to remove the uterus. The operation was performed on October 30th; the patient did not react, but died within twenty-four hours. Prior to the operation, the patient was extremely reduced by her protracted sufferings. Dr. Byford, in a similar case at the present time, would elect the vaginal operation. The specimens removed from the woman were exhibited as supporting the diagnosis of mural pregnancy.

This was the second case of mural pregnancy that had come under the reader's observation within a period of five years. The first case was reported to the Chicago Gynecological Society some time ago. The patient was in labor and moribund when Dr. Byford saw her. She had been in labor until exhausted. There was no difficulty in making a diagnosis. The head was low down in the pelvis, almost on the perineum. The os uteri was well-nigh inaccessible behind and above the symphysis. The body of the uterus, somewhat enlarged, could be felt, in the lower and anterior part of the abdomen, attached to the tumor containing the fetus. The fetus could be felt through the abdominal walls, surrounded by a thick involucrum, apparently as thick as the uterine walls. Fœtal extremities could be distinguished. When dissected, the sac, in which the fetus was contained, was found to consist of a thick layer of muscular fibres. These fibres were directly continuous with those of the uterus. The tubes and ovaries lay on either side of the lower portion of the sac. The fecundated ovum had made its way down the tube, became lodged in a diverticulum in the uterine wall, and was gradually extended into the cavity of the abdomen. The fetus was thus developed within the uterus, though not within the uterine cavity.

The resemblance to normal pregnancy is great in the presentation and position of the fetus, deep down in the pelvic cavity, behind the vagina. The head, in this case, was fixed by the concentric contraction of the uterine fibres, by which it was surrounded, and could be easily outlined as it lay there covered by the posterior vaginal wall.

The specimen presented is much less perfect than the one described, because of the numerous effects wrought upon it during the great length of time it remained in the maternal body, and the mutilation consequent upon emblecation.

The treatment of these cases ought to be considered apart from that of extra-uterine pregnancy at term. It is always a matter for special consideration, in connection with each case as it presents itself, whether or no the removal of the fetus, at term, in extra-uterine gestation, should be attempted. The dangers of laparotomy are greatly increased by the inability to remove the placenta. The surface to which it is attached has no contractile power, so that the divided vessels are left patulous. If hæmorrhage does not immediately prove fatal, the blood is a source of sepsis that must almost certainly destroy the patient. Laparotomy would more likely prove successful, if performed some days after the death of the child. In these cases of ectopic or interstitial uterine pregnancy the fetus may be easily removed through the vagina. An incision made through the posterior vaginal wall would completely uncover the presenting part and enable one to apply the forceps or attach it with the perforator and crotchet, as in ordinary labor. After the removal of the fetus, the placenta should be allowed to separate spontaneously. Since writing this report, Dr. Byford has seen a case, reported in the *Annales de Gynécologie* (July, 1884), occurring in the practice of Mr. Matheson, of England, illustrative of the execution of this plan. "The case was reported to the London Obstetrical Society, under the title 'Extra-uterine pregnancy, the extraction of a living fetus through the vagina.' The child was slightly asphyxiated, but survived. A sponge, saturated with perchloride of iron, was introduced into the sac after removal of the placenta. The mother recovered. It would seem that the author did not suspect his case to be one of interstitial pregnancy. During the discussion that followed, only one of those present expressed the opinion that it was of that variety. Mr. Griffith thought it was either interstitial pregnancy, or one in which the fetus was developed in one portion of a double uterus.

#### DISCUSSION.

Dr. EDWARD WARREN SAWYER thought that interstitial pregnancy meant the development of the ovum in the uterine portion of one of the tubes. In Dr. Byford's case the uterine portions of the tubes were not involved. It reminded him of a case he had seen near Denver. In this case a secondary uterus, with muscular walls, had been developed, but, as the tubes were not involved, he did not feel justified in designating the case one of interstitial pregnancy.

Dr. D. T. NELSON said, with reference to the treatment of the placenta, that Dr. Byford's advice

was that usually recommended in the textbooks. The placenta should be left alone in those cases in which the walls of the secondary uterus were not muscular. He had seen a case in the museum of the Chicago Medical College in which no muscular fibre could be detected in the walls. When the walls of the adventitious uterus were muscular it was questionable whether or no the placenta should be left alone. If the placenta is removed there is danger of hæmorrhage; if the placenta remains there is danger of sepsis. When there was reason to suppose that contractions of the adventitious uterus would check hæmorrhage, he thought that the placenta should be removed. He had had no experience in these cases.

Dr. E. C. DUDLEY replied to Dr. Nelson. Women, in cases of extra-uterine pregnancy, in which the placenta has been allowed to remain, do not die of sepsis. He had seen two or three cases in which the sac had been united to the abdominal incision. Whenever evidence of sepsis occurred the sac was washed out, and the temperature immediately fell to the normal. The placenta, under these circumstances, is spontaneously eliminated in about three weeks.

It required phenomenal powers of diagnosis to tell in the concrete case whether or no the sac had sufficient muscular fibres to prevent hæmorrhage. The placenta should be permitted to remain within the sac.

Dr. J. H. EXNERIDGE thought that if, on microscopical examination, it was found that the muscular fibres of the normal uterus were continuous with those of the adventitious uterus, the case was one of mural pregnancy. In cases of abdominal pregnancy there was a line of demarcation between the normal and adventitious uterus.

Dr. A. REEVES JACKSON thought the members of the society were greatly indebted to Professor Byford for the presentation of such an interesting specimen. He thought, however, with Dr. Sawyer, that the results of the anatomical investigation did not support the author's diagnosis. The uterine portions of the tubes were not involved. So valuable a specimen deserved very close microscopical and macroscopical examination. It ought to be referred to a competent pathological anatomist.

Dr. JOHN BARTLETT thought the ovum had not passed through the tube, but had been developed in the broad ligament beneath the peritoneum, and had in this manner derived muscular fibres from the uterus.

Dr. W. W. JAGGARD referred to the fact that next to ovarian pregnancy interstitial pregnancy was of most infrequent occurrence. Up to the present time about thirty cases (in regard to which the diagnosis was positive) had been reported. Interstitial or mural pregnancy included other sites of development than the uterine portions of the tubes. Dr. Gilbert's case, reported in the *Boston Medical and Surgical Journal* (March 3, 1877), and alluded to by Professor Lusk, in his *Treatise on Midwifery*, was a case in point. The ovum in this case was developed in what seems to be a bifurcation of the Fallopian tube. In Dr. Byford's case the tubo-uterine orifices were not involved. The sac was extrinsic to the uterine walls. It was

probably a case of abdominal pregnancy, in which the ovum became attached to the posterior uterine wall, and derived muscular fibres from its locality. The fact that a continuity of muscular fibres from the normal uterus to the adventitious uterus might be ascertained upon microscopical examination would prove nothing as to the nature of the pregnancy. Dr. Byford's case resembled that of Janvrin, in which the ovum lodged on the posterior uterine wall, and developed in this situation, involving the posterior wall in its sac. The specimen was worthy of more exact investigation, and should be placed in the hands of a competent pathological anatomist.

Dr. SAWYER said that abdominal pregnancy, with location of ovum on posterior uterine wall, was not at all improbable. He then referred to Bischoff's and Leopold's observations and experiments with relation to the "external wandering over of the egg." Beigel had ridiculed this idea. It was like a blind man introduced into a large, empty room, with a thread in his hand, seeking to find and thread the eye of a needle, located in some indefinite quarter of the room. Notwithstanding this sarcasm, the fact of the external wandering over of the egg was a matter of positive knowledge. The egg may pass from one ovary to the opposite Fallopian tube through the abdominal cavity. He thought the specimen exhibited was one of abdominal pregnancy.

Dr. DUDLEY thought the fact of the external wandering over of the egg was not displayed at the present time. Playfair, in his Treatise on Midwifery, gave a clear exposition of the subject.

Dr. CHARLES WARRINGTON EARLE said that the fact of external wandering over of the egg was fully recognized twelve years ago.

Dr. SAWYER said the ovum in abdominal pregnancy might be attached to the posterior wall of the uterus, the mesentery, under surface of the liver, or to other viscera.

Dr. NELSON made the remark that in both of the cases cited by Dr. Byford decidua had been cast off by the uteri.

Dr. JACKSON said that Fränkel was of the opinion that the formation and extension of a decidua was a constant occurrence in extra-uterine pregnancy. It was pathognomonic of the condition.

Dr. W. H. BYFORD was not surprised that certain members did not agree with him in his diagnosis. He thought that in the first case the fecundated ovum passed through the tube, but had found some diverticulum in the uterine cavity, and had passed into the posterior wall, had developed in this region, pushing the wall before it. Some of the reasons for this position were as follows:—

The muscular elements of the sac were directly continuous with the uterine muscle. He did not believe that such a muscular sac could develop adventitiously in the abdominal cavity. He had seen cases of abdominal pregnancy, in which the sac contained no muscular fibre. The head presentation down deep in the pelvic cavity, in the direction of the resultant of the forces developed by uterine contractions, supported his view of the case.

It is not necessary for the production of mural

pregnancy that the tubes be involved. He thought there was much in the remarks of Dr. Nelson and Dr. Dudley. In cases in which there was sufficient contractility it was best to remove the placenta. Even under these circumstances it was not absolutely necessary. There was no danger in allowing the placenta to remain.

Finally, he was very positively of the belief that the two cases referred to in his paper were examples of mural pregnancy. The peritoneum was a boundary line between mural and abdominal or peritoneal pregnancies.

Dr. SAWYER asked the question: Is the peritoneum a boundary line of importance in the macroscopical or microscopical differential diagnosis between abdominal and mural pregnancies?

Dr. JAGGARD, in reply, said that the peritoneum was no barrier. What was the peritoneum? Dr. Etheridge, in an article on "Chronic adhesive perimetritis," published in a recent number of the *Chicago Medical Journal and Examiner*, had ably sketched the anatomy of the membrane. It was developed out of connective tissues, according to Kündelisch and other distinguished anatomists. It offered absolutely no barrier to the attachment of the ovum to the posterior uterine wall, and its development in this situation, with the derivation of muscular elements from the normal uterus.

On motion, Doctors Byford, Merriman, and Jaggard, were appointed a committee to select a competent pathological anatomist, who did not belong to the Society, to examine the specimen and report at the next regular meeting. It was specified in the resolution that the pathologist should be amply paid for the labor.

#### PLACENTA WITH CALCAREOUS DEPOSITS.

Dr. ETHERIDGE then exhibited a placenta with calcareous deposits. The placenta was removed from the body of a woman, pregnant for the first time, who had probably carried the fetus 292 days. The calcareous deposit was probably the result of fatty metamorphosis of the upper layers of the *decidua serotina*.

Dr. SAWYER said the placenta was interesting but not uncommon. It has been erroneously believed that such placenta are of syphilitic origin. He thought the connection with prolonged gestation was established.

Dr. DUDLEY referred to the calcareous deposit in the walls of the arteries supplying an ovarian cyst, which he had removed some years previously.

Dr. JACKSON related the history of a case, in which he had removed a mass of calcium carbonate situated in the recto-vaginal septum, one and one-half inches from the vulvo-vaginal orifice. There was no fatty metamorphosis in this case.

Dr. EARLE thought there was an unreasonable tendency to ascribe such cases to the effects of syphilis. Hydatidiform degeneration of the chorionic villi and hydrops amnii received a similar erroneous etiology.

Dr. ETHERIDGE said that the deposits were composed of phosphate and carbonate of calcium. These salts had an affinity for albumens and fatty acids present in the cotyledons. Similar calcareous deposits were met with in fibroids, thrombi, encysted

trichinae, and in the lithopædia of extra-uterine pregnancy.

Dr. W. H. BYFORD thought the connection between prolonged gestation and calcareous deposits in the placenta was established. He thought that Dr. Etheridge would find on microscopical examination that the changes had occurred exclusively within the vessel wall.

The Society then adjourned to meet on the third Friday evening in January, at the residence of Dr. E. C. Dudley, No. 2317 Indiana Avenue, at eight o'clock.

The business of next meeting will consist of:—

(1) Report of the pathologist, Dr. Christian Fenger, on Dr. Byford's specimens.

(2) Exhibition of specimens from a double ovariectomy, by Dr. E. C. Dudley.

(3) Discussion of certain methods by which the second stage of labor may be rendered easier, by Dr. Henry F. Byford.

#### FIRST MEETING OF THE AMERICAN SOCIETY OF PUBLIC ANALYSTS.

##### ELECTION OF OFFICERS.

DECEMBER 4, 1884. At the meeting of the American Society of Public Analysts, held at the rooms of the Brooklyn, N. Y., Department of Health, the following officers were chosen for the ensuing year: Dr. E. H. Bartley, of the Brooklyn Health Department, President; Dr. Cyrus Edison, of the New York City Health Department, Vice-President; Prof. E. W. Martin, Assistant Dairy Commissioner of New York, Recording Secretary; and Dr. Wm. K. Newton, Milk Inspector of New Jersey, Treasurer. There were twenty members present.

##### THE EFFECT OF COWS' FOOD, ETC., UPON THE MILK.

There was an extended discussion upon the relation of the sanitary condition of cows and cow stables to the public health, and upon the effect of the different foods, especially brewery grains, upon the milk. In regard to this last question the recent experiments at the New York Agricultural Experiment Station at Geneva, N. Y., are of exceptional interest. The cows there fed upon *fresh* brewers' grains have given as high as 21.43 per cent. of milk solids and 12.53 per cent. of fat, while 2.97 per cent. of fat has been the lowest. Upon the different feed the cows have averaged over fifteen per cent. of milk solids. In the opinion of the director, *fresh* brewers' grains seem to have no injurious effect upon milk. In this opinion several of the analysts did not agree, although it would seem to be supported by experience in Massachusetts.

There was also a diversity of opinion as to whether a food containing an organic acid, such as acetie, produced an acid condition of the milk, or whether it acted, as is well known lemon juice does, upon the urine to produce a neutral or even alkaline condition, from being decomposed into the carbonates. The discussion upon these subjects was adjourned to the January meeting, which will be held at the rooms of the New York City Health Department.

For the February meeting are especially assigned the subjects of the proper legal minimum limits of quality for milk and of the methods of assay. All analysts particularly interested in these subjects are invited to attend and take part in the discussion.

#### Recent Literature.

*Manual of Dermatology.* A. R. ROBINSON, M.B., L. R. C. P. & S., Edinburgh. Published by Birmingham & Co., N. Y. 1884.

"This volume is intended to be the basis of a future, much larger, more pretentious, and more original work. In its present form an effort has been made, not so much to write an original work with an elaboration of my own personal views, as to present to the subscribers of 'Birmingham's Medical Library' a concise account of our present knowledge of the subject of Dermatology." The foregoing extract from the preface gives the author's views of the scope and *raison d'être* of the book, and his well-known and excellent work in the normal and pathological histology of the skin, renders the portions of the book devoted to these subjects of more than ordinary value, and justifies the expectation and hope, that in the "future, much larger, more pretentious, and more original work," this part of dermatology will receive more extended and detailed attention than is permitted by the limits of the present volume. The anatomy, physiology, and diseases of the skin are discussed after the conventional manner and scheme of the textbooks, the classification used being that of Hebra, and the work, although well done, gives evidence of having been done to order, with limitations of time and space, conditions which are not conducive to the highest degree of excellence. The diseases omitted from consideration in this book are Myxedema, Pityriasis Rosea, Erythrasma, Pellagra, Framboesia, Xeroderma pigmentosum, and Dermatitis papillaris capillitis, mention of which at least should be included in any treatise upon diseases of the skin. This is the only treatise upon dermatology in the English language, however, in which we have seen stated, with the fulness which they deserve, the characteristics of syphilitic eruptions as selected and arranged by Kaposi, there being nothing which so facilitates the diagnosis of cutaneous syphilis as an intelligent appreciation and application of the rules laid down by the eminent professor of dermatology in Vienna. The drawings of the pathological histology of the skin are excellent, but those showing the gross appearances are not good. The volume is not a creditable specimen of the publisher's art, possessing a fault which is much too common in American publications, the fault of being very heavy and awkward, and in this respect anything but a "manual." It is an octavo of 655 pages and weighs two pounds and twelve ounces avoirdupois; while a similar volume of Ziemssen's handbook, containing nearly one hundred more pages, weighs one ounce less, and one of the volumes of Trousseau's "*Clinique Médicale*" containing over two hundred more pages, weighs six ounces less.

# Medical and Surgical Journal.

THURSDAY, JANUARY 8, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by CUPPLES, UPHAM & CO., Boston. Price, 15 cents a number; \$5.00 a year, including postage.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUPPLES, UPHAM AND COMPANY,

233 WASHINGTON STREET, BOSTON, MASS.

## VIVISECTION OR ANTIVIVISECTION; WHICH IS THE MORE HUMANE?

The letter from our London correspondent, printed in another column, calls attention to an event well fitted to stir the emotions both of the profession and of the public. It is sure to interest the profession, because it constitutes the first realization of the hope that certain forms of brain tumor, one of those dread diseases which sap the sources of happiness by attacking the sacred contents of the cranium, are likely to show themselves amenable to the swift cure of the surgeon's knife. And the public—the English public at the least—cannot fail to lend a respectful ear to the signal and speedy vindication of the physiologist to whose labors this result is largely due, when it remembers that only three years ago he was held up to popular indignation, in the public courts, on account of the very experiments, without which—or the like of them—this avenue to the relief of human suffering would never have been opened.

The first of the brilliant series of investigations in this department of cerebral physiology was made and published in 1870, by Fritsch and Hitzig, in Berlin.

Through them the fact was established, which the theories of Hughlings Jackson and the anatomical studies of Meynert had already foreshadowed, that one part of the ganglionic mass spread over the surface of the brain is the breeding-place of the impulses which move the muscles of the body, each muscle or group of muscles having its representative spot within the cortex cerebri, and responding by its contraction to the localized stimulation of its motor centre by electricity.

It needed but one step further to show that, in like manner, the sensory surfaces of the body are represented in other portions of the cortex, which thus, in Meynert's phrase, deserves the name of the ultimate "projection surface," on which all the actions and reactions of the body are, as it were, depicted.

The investigations of Ferrier, though not made public until several years later, had been in reality

carried on independently of those of the German observers and simultaneously with them, and he has continued ever since to hold a prominent place among the many able investigators who have labored in the same field.

Most of our readers are aware what an impulse was given to the study of localized convulsions and paralysis, under the able lead of Dr. Hughlings Jackson, by this discovery of the motor functions of the cortex cerebri; and how the teachings of comparative anatomy were invoked to aid clinical and post-mortem observation, in the patient effort to apply to man the facts won from experiments upon the lower animals.

Nor was it long before surgery began to seek its share in the brilliant results. Careful charts have long since been prepared to show the relation of the motor and sensitive centres in the cortex to the outer surface of the skull, in order that the exact position of splinters of bone or of abscesses might be diagnosed before trephining, by a study of the symptoms which they produced. The hope that tumors might be localized and removed has been canvassed as a possible prize for the surgery of the future, but the present case, in which the diagnosis was made by Dr. Hughes Bennett, and the operation performed by Mr. Godlee, is, so far as we know, the first realization of this dream.

We quote a few extracts from the dramatic story, as it is given in a letter by an F.R.S. to the *London Times*: "While the Bishop of Oxford and Professor Ruskin were, on somewhat intangible grounds, denouncing vivisection at Oxford, last Tuesday afternoon, there sat at one of the windows of the Hospital for Epilepsy and Paralysis, in Regent's Park, in an invalid chair, propped up with pillows, pale and careworn but with a hopeful smile on his face, a man who could have spoken a really pertinent word on the subject, and told the Right Rev. Prelate, and great art critic, that he owed his life, and his wife and children their rescue from bereavement and penury, to some of those experiments on living animals which they so roundly condemned. . . . The patient had the position in which he stood faithfully explained to him. He was told that he labored under a malady which medicines were powerless to touch, and that if left unassisted he must die in a few months at latest, after prolonged sufferings similar to those which had already brought him to the verge of exhaustion, and which could only be partially alleviated by drugs; but that one outlet of escape, narrow and dangerous but still an outlet, was open to him in an operation of a formidable nature, and never before performed on a human being, under which he might perhaps sink and die, but from which he might perhaps obtain complete relief. The man . . . eagerly chose the operation. On the twenty-fifth ultimo, accordingly, Mr. Godlee, surgeon to the University College Hospital, in the midst of an earnest and

anxious band of medical men, made an opening in the scalp, skull, and brain-membranes of this man at the point where Dr. Hughes Bennett had placed his divining finger. . . . In the substance of the brain, exactly where Dr. Hughes Bennett had predicted, a tumor the size of a walnut was found—a tumor which Mr. Godlee removed without difficulty. The man is now convalescent, having never had a bad symptom. . . .

"He has been snatched from the grave and from much suffering, and there is a good prospect that he will be restored to a life of comfort and usefulness. In that case he will be a living monument of the value of vivisection. The medical profession will declare with one voice that he owes his life to Ferrier's experiment. . . .

"Many men and women will henceforth, there is reason to anticipate, be saved from prolonged torture and death by a kind of treatment that has been made practicable by the sacrifice, under anaesthetics, of a few rabbits and monkeys."

The thrust against the antivivisectionists contained in the last paragraph is a fair one.

It is a truism to say that we sympathize with the *motives* of those gentlemen who in England have been seriously retarding the advance of physiological knowledge, but the question is not of their motives; it is of their wisdom and their judgment, and it must be admitted that their position has been illogical, and the results of their action, on the whole, mischievous. Their position has been illogical because *à priori* arguments against vivisection were untenable, and yet there were no other arguments which they could fairly claim the right to use. No one could assert that it is never allowable to inflict pain on animals; the argument is thrice every day refuted. Neither is it germane to the subject to say that some experiments are cruel and unnecessary. It would be remarkable if this were not so. The only real question is the practical one; "Do the results, on the whole, justify the means?"

Many English laymen—not generally conspicuous for their hostility to "sport," but assuming themselves to have more humanity than the medical profession, whose business it is to relieve suffering, and more ability to judge of the probable outcome of physiological investigations than the men who make these studies their life-work—have sought to answer this question sweepingly in the negative.

In this instance the facts are sternly and reprovingly against them.

In November, 1881, Professor Ferrier was summoned before the Bow Street Police Court to answer the charge of violating the Vivisection Law, in demonstrating before some members of the International Medical Congress certain of the monkeys which had previously been operated on by Professor Yeo in the course of the experiments above alluded to.

The charge was not sustained, and the case was dismissed; but the verdict of cruelty, which was rendered against him by many of his countrymen, has stood unreversed until now, when history, with timelier justice than it is her wont to show, comes forward to testify publicly in his behalf.

Of course some physiologists are cruel, and we ought to be grateful to any one who says, not that because of the exceptional cruelty, all investigation by vivisections must stop, but that in order that investigation may go on the cruelty must stop. The question as to what investigations are worth making can only be decided, as it is daily being decided, by the voice of men who are the peers of the investigators themselves. Meantime it will not do for the public to stigmatize the chariot of science as the car of the Juggernaut, simply because there are stains of blood upon its wheels.

#### PHARMACOMANIA.

This felicitous term was invented by Dr. Austin Flint, and employed by him in his recent address before the New York State Medical Society, to indicate "a form of mental aberration affecting alike certain physicians and patients." The pharmacomaniacal practitioner has unshaken faith in the power of medicines. He does not believe in the *laissez faire* system, which credits nature with a large share in the cure of the patient. The natural evolution of disease, and the mighty struggle toward recovery, notwithstanding even the opposition of uncongential and obstructing remedies, are subjects to which he has devoted little attention. The sick-room is his opportunity, the vast resources of the pharmacopoeia his means. He goes for every symptom with a corrective, and for every congeries of symptoms with a specific.

The formidable array of bottles and glasses at the bedside of the patient testifies to the assiduity and zeal, and the long bills of the apothecary after the sickness is over also bespeak the unsparing devotion, of the medical attendant. He changes his medicines often, just as often as he sees that they are doing no good, or as new symptoms arise, and he diligently and early tries all the new remedies, especially such as bear the strong endorsement of the proprietors. In fact, he prides himself on being a progressive man; reads his medical journals to find what recent discoveries have been made in the treatment of disease; and "runs" every new medicine till something never appears.

The pharmacomaniacal patient also has great faith in dosing, and demands when sick a liberal administration of drugs. Even his slight ailments—a cold, a sore throat, must receive the earnest attention of his family physician, who is called out of bed to order repeated small doses of aconite or

<sup>1</sup> See this Journal, vol. cv. p. 592, London Letter.

a mild laxative. Individuals of this class are always taking medicine, for they always have, or fancy they have, some physical derangement which, if neglected, may prove serious. This morbid craving for drugs is fostered by homoeopathy, and the unfortunate victim finds satisfaction only in a practitioner of that school; in fact when pharmacomania ceases to have existence, there will no longer be any place for homoeopathy.

The above address of Dr. Flint gives some excellent hints as to the conduct of the physician in the presence of his patient. There are some physicians that are naturally optimistic; they are sanguine and hopeful, and inspire hope, cheerfulness, and confidence. They believe that, despite certain discouraging symptoms, their patients will get well; they emphasize all the favorable indications and are slow to recognize the unpropitious features of the case. Such practitioners will lose patients and be blamed for a wrong prognosis; they will also meet with success where nothing but the confident assurance with which they managed to inspire the patient, and the powerful stimulus to the vital forces of persuasive hope, could have turned the scale in the direction of recovery. The picture illustrative of the opposite extreme is that of a practitioner "who assumes the responsibility of a case always anticipating the worst that can befall a patient." "His solemn manner and melancholy mien inspire nothing but forebodings."

Such pessimists in medical practice exist in every community. They will be successful in cases when they expected to fail. On the other hand a gloomy prognosis and a discouraging demeanor may, by their influence on the mental state of the patient and the loss of appetite and of sleep, the depression of the organic functions generally which follow, take from him his only chances of recovery.

The whole subject of non-medicinal therapeutics, and especially of mental therapeutics, is of the utmost importance, and claims the earnest study of the practitioner who would be something more than a dispenser of drugs; who would intelligently employ every agency on which the restoration of his patients may depend.

#### DR. JEFFRIES' AERIAL VOYAGE ACROSS THE ENGLISH CHANNEL IN 1785.

In connection with the recently announced, though not yet practically demonstrated, discovery by a Frenchman of a method of steering balloons, and, by thus enabling them to beat against the wind, for utilizing them for aerial navigation, the first successful attempt to cross from England to France in a balloon one hundred years ago yesterday has a peculiar interest. This attempt and its success were mainly due to the scientific enthusiasm

and nerve of a Bostonian and a medical man, Dr. John Jeffries, who provided the necessary expenses—about £700—and personally superintended the preparations, and shared the dangers and novelties of the voyage with a Frenchman named Blanchard, whom Dr. Jeffries had accompanied on one of his three previous ascents over *terra firma* in England.

Hitherto nothing of a scientific character had been attempted by any of the balloonists, but Dr. Jeffries, in his own words, "wished to see the following points more clearly determined: first, the power of ascending or descending at pleasure while suspended and floating in the air; second, the effect which oars or wings might be made to produce toward the purpose, and in directing the course of the balloon; third, the state and temperature of the atmosphere at different heights from the earth; fourth, by observing the varying course of the currents of air or winds at certain elevations, to throw some new light on the theory of winds in general."

In his experiments he was aided by Sir Joseph Banks, the then president, and Dr. Blagden, the secretary, of the Royal Society, to which learned body his experiences on these voyages were subsequently detailed. On the voyage across the channel the balloon left the cliffs of Dover on a favorable day at a quarter past one, and after various adventures landed in France, twenty miles from the sea, at a quarter before four. One little item showing the professional ingenuity of Dr. Jeffries is not amiss in the pages of a medical journal. At one period the balloon threatening to descend, in spite of everything in the way of ballast or incumbrance having been discarded, the doctor proposed to his companion that each should take a bladder and pass as much as he could, and "reserve the throwing it away at the very instant of descent to break the force of the shock."

Those who would follow all the incidents of this voyage, and the ovation which the travelers met with in Paris, are referred to a very entertaining article by Dr. B. J. Jeffries, in the *Magazine of American History* for January, largely made up of extracts from his grandfather's diary.

Since this attempt, on January 7, 1785, steam and electricity have yielded up many of their mysteries, and the course of travel and commerce has been revolutionized through their instrumentality, but "the effect which oars or wings may be made to produce toward the purpose of ascending or descending at pleasure while suspended and floating in the air, and in directing the course of a balloon," is nearly as far from a solution as it was then.

Were our quondam townsman and professional ancestor alive now, he would probably be no less astonished at what has not been done in this direction than he would be at what has been accomplished with the other agents.

## MEDICAL NOTES.

## NEW YORK.

— A very sad case of the cutting short of a brilliant professional career in its early prime has occurred in Brooklyn. Dr. George H. Atkinson, one of the most prominent of the younger practitioners of that city, died on the twenty-seventh of December, of cerebral syphilis, which was contracted by means of a scratch on the finger, received while operating on a patient in August last. Dr. Atkinson was born in Portland in 1851, and was graduated at Dartmouth College in 1871. He received the degree of M.D. from the Long Island College Hospital, Brooklyn, and was soon afterward appointed assistant surgeon to the hospital. More recently he was made surgeon, and also became a lecturer on surgery and genito-urinary diseases at the college. Just at the time of Dr. Atkinson's death, a man died in New York from septicæmia, caused by a poisonous animal virus taken into the system in handling hides, after receiving an abrasion of the arm from a fall.

— The annual meeting of the managers of the Mount Sinai Hospital was held on December 28th, when it was announced that 2,078 patients, of whom 95 per cent. were free, were treated during the year. In the out-door department there were 40,300 consultations.

## CHICAGO.

— During a number of years past students attending Rush Medical College have had their physical endurance taxed to the extreme limit of listening to an average of between seven and eight lectures daily. The time-card has recently been rearranged, and the number of daily lectures reduced by one.

— The new administrative building of the Cook County Hospital was formally opened on Thanksgiving day by a public reception, a supper, and a dance. The building is a magnificent structure in its architectural appearance, and in all its appointments for the purposes which it is to serve. It contains the general offices of the institution, reception-rooms for visitors and for patients, the residence of the warden, etc., etc. Considerable public criticism has been made on the lavish expenditures incurred in fitting up this building and in furnishing it, but the county commissioners do not appear to be greatly disturbed by them.

— Prof. Germain Sée, in the chapter on the Pathogeny of Influenza (Grippe) in his forthcoming volume on the diseases of the chest, summarizes his observations into the following ætiological definition (*Le France Médicale*, November 27, 1884): "Influenza is an epidemic, non-contagious disease, independent of conditions of warmth, appearing to be due to an atmospheric agent, and having for its essential characteristic a contracted irritation or true inflammation of the respiratory tract and organs."

## Correspondence.

## LONDON LETTER.

[FROM OUR LONDON CORRESPONDENT.]

LONDON, December 17, 1884.

THOUGH not in the habit of intruding my communications upon the notice of your readers very frequently, I feel there is now real occasion for me to write. About three years ago I furnished you with some account of the scandalous criminal persecution, under the misnomer of prosecution, which was abortively attempted at Bow Street, and from which our honored confrères, Professors Ferrier and Gerald Yeo emerged technically scathless. No one who knows the prejudice of a large section of the British public, and is conversant with the unprincipled persecuting slander of antivivisectionists, can doubt but that Professor Ferrier's professional income would have been destroyed had not the professional appreciation of his great worth tended to counterbalance the prejudice against him which was excited in the minds of the public at large; who, of necessity, from their consummate ignorance of physiological matters were too easily impressed by the plausible clamor of the loud-sounding antivivisectionists.

The wheel of time, or Sir Walter Raleigh's wheel of fortune, has indeed made its half turn with most happy and scarcely anticipated speed.

The current has changed; we may now almost predict as hearty and general a condemnation of the senseless outcry against vivisection as we have experienced in the opposite direction. The unmistakable evidence of this prompts my letter to-day. Enclosed is a letter which appeared in the *Times*<sup>1</sup> of yesterday, the 16th inst.

It is hardly necessary to inform your readers that, after its comic contemporary *Punch*, the *London Times* has no serious rival in the influence it sways over British public opinion.

This letter was made the subject-matter of a two-column leading article in yesterday's *Times*, which ably, argumentatively, and authoritatively exposed the untenable and irrational position occupied by the antivivisectionists, and set forth the necessity, usefulness, and righteousness of vivisection. It can no longer be doubted that the accession of statesmen to the responsible positions now occupied here by politicians will result in an enlightened and really liberal modification of the legislative acts which now so restrict vivisection as to all but "Burke" its practice in England. The *Times* scored a point in publishing the fact that a justly eminent English physiologist and medical practitioner, when told by the Home Office "to wait some months before again applying for the license which could not just then be granted," had listened to the dictates of his conscience and had expatriated himself until he could return to his benighted and native land after having concluded that research which the lives and interests of fellow-creatures forbade him to delay.

THE MILLER MEMORIAL HOSPITAL AT GREENWICH.

This hospital was opened to-day by the lord mayor of London, who, by virtue of his office, is

<sup>1</sup> See editorial pages 41, 42.

the chairman of the Metropolitan Hospital Sunday Fund. The hospital, which is an extension of, or rather an addition to, the Royal Kent Dispensary, has been founded by funds raised to perpetuate the memory of the late Canon Miller, D.D., vicar of Greenwich, particularly in connection with his origination of the Hospital Sunday movement.

Exceptional interest attaches to this most recent development in hospital construction; for now for the first time in modern times is the opportunity furnished for testing the practical working of the system of circular wards. The hospital committee have distinguished themselves as being the first of such bodies to promptly recognize the great claims of this novel system, and to boldly afford it a complete trial. The awkwardness and limited area of the available site doubtless had much influence in securing an acceptance of the circular system of wards. Indeed, it was soon evident that no other scheme would enable the site to accommodate a hospital which satisfactorily met modern requirements.

The Hospitals Association held its first general meeting to-night, and very appropriately devoted the occasion to the consideration of hospital circular wards. The objects of the Association are: (1) to facilitate the consideration and discussion of matters connected with hospital management, and, where advisable, to take measures to further the decisions arrived at; and (2) to afford opportunities for the acquisition of a knowledge of hospital administration.

Under the presidency of Dr. Buchanan, the chief medical officer of the Local Government Board, the official successor to Mr. John Simon, a representative gathering listened to an instructive and interesting discussion. Prof. John Marshall, F.R.S., senior surgeon to University College Hospital, delivered an address on Hospital Circular Wards, which in 1878 he was original in advocating in England. With characteristic frankness he to-night gave the completest history he had been able to deduce concerning the priority of the idea of circular hospital wards. With him the idea was suggested by the many difficulties experienced in endeavoring to devise a sufficiently commodious new hospital, up to modern ideas, and capable of standing on the site of the present University College Hospital. His views were furnished in a paper read before the Cheltenham meeting of the National Association for the Promotion of Social Science, in October, 1878. This paper speedily appeared in print, with valuable remarks and illustrations by Mr. Gordon Smith, the architect to the Local Government Board. This publicity presently brought to Professor Marshall's knowledge the fact that some four or five years earlier the foundations for a hospital with circular wards had been laid at Antwerp. The architect who furnished the designs for this Belgian circular-ward hospital had succeeded so far in imbuing others with his belief in the soundness of the principle as to be able to occupy the site with the foundations of his hospital building. However, a too-cautious spirit then prevailed, and the work was stopped through fear to sink the necessary money on an "experimental" construction of such magnitude. At the same time the architect, bold in the consciousness of the excellence of the

principle, declined resolutely to depart from it. His perseverance was ultimately rewarded, and the hospital has now been practically complete for some little time, though it is still unopened. Professor Marshall has visited this hospital, and with much feeling described the very great satisfaction with which he had critically viewed in substance the realization of his ideas. He had not dared to anticipate that he would see them carried out, though he had from the first felt that the scheme would not be permanently neglected in the face of its numerous unique advantages. He was most struck with the power and general diffusion of daylight, which permeated every portion of even the largest circular wards. No surgeon could expect a better daylight illumination in any hospital ward than was present in every part of these Belgian circular wards.

The *système circulaire*, mentioned by certain French authors on hospital construction, had proved to consist of nothing more than a circular arrangement of the ordinarily shaped buildings of a hospital. Professor Marshall had learned from Sir Andrew Clark (not the physician, but the scientific soldier, the director of fortifications) that the latter had more than once designed circular hospital wards for military purposes, but that political and military rather than medical or other grounds had hindered his plans being carried out. Professor Marshall clearly established then that, so far as he knew, the Belgian architect, Sir Andrew Clark, and himself had separately and entirely independently deduced the principle of circular hospital ward construction.

Professor Marshall considered a diameter of about sixty-five feet the greatest that could in practice be recommended for circular wards. He advocated, where possible, only single floors of wards; but did not disallow a second floor of wards, while, however, he considered that three tiers of circular wards would prove to be the limit that should ever be sanctioned. The top of the circular-ward towers might be used, as in the Belgian hospital, for a sun-room under suitable climatic conditions. Referring to octagon wards, an example of which is to be found at Bristol, not to go farther, he remarked that the angles of a rectangular were its worst features, and that in an octagon ward the angles were doubled in number. He did not consider any polygonal ward could possess the advantages which were essentially peculiar to the truly circular ward. He recommended a somewhat domed ceiling, with central ventilation outlet, and quoted various experiments to prove how a flat ceiling hindered the exit of foul air. He had been struck with the cheerful, homelike, well-lighted, workable appearance of the circular wards, which, having been opened at Greenwich to-day, are believed to be the first in occupation which have been constructed for hospital purposes. Professor Marshall read a letter from Lady Strangford accompanying a plan which showed that her extensive practical and devoted service in the East had resulted in the design of a hospital with four central, circular, windowless, one-storied wards. This construction she had found to be the most comfortable, cool, convenient, and suitable under the climatic conditions obtaining in Egypt. The ventilation outlet was in the dome, while air

entered by three doorways, so that an agreeable draught was favored, without heat or glare being unduly admitted. Mr. Keith Young, the architect of the Miller Memorial Hospital, gave a succinct description of the building. This gentleman has on various previous occasions rendered himself conspicuous among architects by the intelligent painstaking and unprejudiced care he has taken in developing every worthy suggestion upon hospital construction, regardless of the crude form in which it may have emanated from the medical officers using hospitals. To this architect the London Fever Hospital is indebted for the approximate perfection of its newest structural addition.

The Miller Memorial Hospital, which is necessarily of modest dimensions, may be briefly described. The plan includes a central administrative block, complete with its various offices. At either end, a circular-ward tower, though only one such has at present been constructed. This ward tower contains a ground and first-floor ward, each thirty-five feet in diameter, designed to accommodate ten beds, each of which will thus have ninety-six feet of free floor-space, ten feet of wall-space, and 1,128 feet of cubic space; the height from floor to ceiling being twelve feet. A slightly greater allowance per bed obtains in the upper ward, where the wall thickness is less. There are eight windows in each, giving the proportion of one foot of glass to every seventy-three feet of cubic space. Three hot-air ventilating boyds are arranged in the centre of the ward, around an equilateral triangle with each angle truncated; the separate smoke-flues are partitioned by thin metal from the up-cast ventilating-shaft, wherein a current is assisted by the proximity of the warm smokestacks. The floor boards are rendered impervious by the paraffin process. All the angles in floors, ceilings, windows, and doors, are rounded, and no mouldings of any kind are used in the wards. The necessary ward offices are in a projecting building cut off from the ward air by a cross-ventilated lobby. The construction throughout has been fireproof, and the drainage on the most approved principles. The total cost of the building has been £3,812, or about £160 per bed. This cost per bed, however, will be materially reduced when the second ward tower is constructed. It is noteworthy that the actual cost has come rather within the estimated outlay. The architect does not claim the hospital to be a fair example of the many advantages afforded by the circular system of wards, but as clear evidence that circular wards can be successfully planned on a site where no commendable rectangular ward would be possible.

The circular form in itself is of pleasing appearance, and the lighting has the effect of being much greater, in proportion to the ward, than it really is.

Sir Andrew Clark furnished the following most interesting data upon the subject under debate. His thoughts were turned to the feasibility and desirability of circular hospital wards by the earnest suggestions of Dr. McKenna, a Scotchman, practising in Melbourne, who, in 1851, was interested in urging the adoption of circular wards in the design for a hospital then in contemplation at Melbourne. Dr. McKenna's advocacy of circular

wards had been suggested by his clinical observations during an extended medical and surgical experience amidst the sick and wounded of the rival factions contending in rebellion in South America. There he treated his sick and wounded in the convents and convent-churches of the country. The convent-rooms, his wards, were roomy but rectangular; the convent-churches were invariably circular and domed. In the former his cases did badly; in the latter they fared marvellously well. Comparable cases occurring simultaneously differed so much in their progress, according to whether they were ward in rooms or churches, that he became convinced of the structural superiority of the latter for hospital purposes, and was unable to trace the difference to any factor other than the circular shape and domed roof of the churches.

Pondering on Dr. McKenna's experience, Sir Andrew Clark investigated the relative sickness per individual bed in rectangular barrack-rooms. As a result, he was led to abolish corner beds, as these showed an unquestionably excessive sick-rate. Sir Andrew Clark was in Rome during the war of liberation, and, finding very large numbers of the sick and wounded quartered in the Pantheon, he immediately bethought him of shrewd McKenna's teaching. At such a time it was difficult to attain accurate statistics; however, the able and patriotic physician whom Italy highly honored expressed himself as surprised and satisfied with the progress made by cases under treatment in the Pantheon.

Regarding the ventilation of domed circular chambers, Sir Andrew Clark had a curious accidental experience. When visiting the Taj Mahal, that splendid domed circular tomb at Delhi, with a large party, in the hot weather, he let fall from his card-case a slip of tissue-paper which, much to his surprise, he presently saw floating steadily upward toward the centre of the dome. This phenomenon he noticed repeatedly when he subsequently tried the same experiment in various parts of the large circular-domed temple at Calcutta. He was convinced of the fact of a natural air current setting upward in the midst of such shaped chambers, but was completely at a loss to find an hypothesis in explanation. At the present time he is constructing two military hospitals with circular wards, one at Milton, the other at Seaforth. The situation and circumstances of the latter would be such that there would be every opportunity for giving facilities such as Dr. George Buchanan had coveted for the purpose of carrying out experiments with a view to devising a system of automatic hospital-ward ventilation, such as had proved invariably impracticable in rectangular wards, but such as there was now reasonable ground for supposing might prove applicable to circular wards.

At the present time additional poor-law infirmary accommodation is being provided at Hampstead by the erection of a circular tower of wards, while some Manchester architects are putting up a circular-ward hospital at Burnley, and Sir Andrew Clark has in hand a large hospital of similar design at Valetta, Malta, where the building promises to present an imposing and pleasing effect. Thus, with the early occupation of the Belgian hospital, we shall soon be in a position to judge of the prac-

tical working of circular wards, both large and small, in both civil and military practice, under various conditions of climate, and with the details independently treated.

Though adverse, not to say hostile, criticism was freely forthcoming in to-night's discussion, it turned very markedly against its authors, who, without exception, were driven to confess that they had never visited a circular hospital ward. On the other hand, Dr. George Buchanan, than whom it would be difficult to discover a more discreetly cautious official, announced that his visit to the Miller Memorial Hospital had sufficed to dissipate his forebodings concerning circular wards. He found them light, cheerful, snug, convenient, and presentable. He ventured to surmise that possibly the circular form of ward would give such advantages as might warrant some reduction in what was now considered the minimum of space appropriate per bed.

To-night's meeting proved an auspicious inauguration of a society from which much ought to result, if their work is useful in proportion as their objects are pretensions. Time must settle this; but just now this overlegislated little territory is everywhere studded with organizations proposing to regulate the business of other persons, and contriving to aggrandize a few honorary officers, while feeding an official who seems to take hearty and disinterested concern in the vitality of the society of busy-bodies.

## Miscellany.

### OBITUARY.

DR. HENRY A. MARTIN.

DOCTOR HENRY A. MARTIN, who died in Roxbury, Massachusetts, December 7, 1884, was born in London in 1821, was graduated at the Harvard Medical School in 1845, and immediately entered upon an active and successful career as a physician and surgeon. Of a daring and ambitious temperament he soon made his name known in local circles as a skilful accoucheur and surgeon. He had, at an early date, become practically acquainted with variola and vaccinia, and eventually became the leading authority on these subjects in America; so that when, in 1870, he introduced the Beaugency animal virus into this country, it at once became widely known, and effected a revolution in vaccination which has added immensely to the efficiency of its protection. In 1877, as chairman of the committee on animal vaccination in the American Medical Association, he made a full report on that subject, which appeared in the published volumes of the "Transactions," and was widely quoted from and reviewed by the Edinburgh and other influential journals.

It was, however, as a surgeon that his name became best known, and in 1862, on the breaking out of the War of the Rebellion, after an examination before a medical board in Philadelphia he was appointed staff surgeon. In that capacity he performed long and efficient service, at Fort Monroe, then as medical director of the department of Southeastern Missouri, where, in that fever-laden country, he became ill, and was

obliged to accept a leave-of-absence to regain his health; next, as medical director at Norfolk, Portsmouth, and Newbern, and then in the army of the Potomac, as surgeon-in-chief of the first division of the second army corps, under General Miles, which position he held until near the close of the war. On his resignation he received a brevet lieutenant-colonel for "gallant and meritorious services," the expression being a compliment rarely paid to a medical officer.

In the "Medical and Surgical History of the War" his name is referred to in connection with a "Ligation of the femoral artery after a gun-shot contusion of the femur," a "Primary resection of the upper third of the femur," and many other important operations; and an illustration is given of an apparatus invented by him for "Extension after excision of the humerus," an instrument which was reported upon favorably by a board consisting of Drs. Woodward, Curtis, and Otis.

On his return home an extensive general practice awaited him, but he paid particular attention to surgery, and gained great repute in diseases of the rectum and hemorrhoidal tumors. In 1877 he brought before the profession the use of the rubber bandage in the treatment of ulcers of the leg, and the value and efficacy of this method were soon acknowledged in this country, and still more generally abroad. In England he first called attention to it by an article in the *British Medical Journal*, of October 25, 1878, and its use became very extensive and gave him a wide reputation there and on the continent. In 1878 he made public his operation of "Tracheotomy without tubes," which he many times successfully performed.

By invitation, he attended the meeting of the British Medical Association, in June, 1881, and was courteously and warmly received by the eminent members of that body. He also took part in the meetings of the International Medical Congress of that year, and there read a paper on the use of the rubber bandage after aspiration of the knee-joint for synovitis, based upon more than one hundred and forty successful cases in nine years, necessitating more than four hundred punctures, all performed without antiseptic precautions other than cleanliness of the needle.

Dr. Martin was gifted with remarkable conversational powers, and was a fluent and ready speaker in public—frank and outspoken in the expression of his opinions, generous in his acknowledgment of the merits of the inventions of others which he believed worthy, but unsparing and scathing in his criticism of all that he judged unworthy. Proud and imperious by nature, and often impatient in temper, he brooked no personal affront, and knew no fear of personal consequences in his bold and vigorous attacks on opponents. His knowledge of the old medical and surgical writers was very great, and his memory so retentive that it was easy for him to quote their views and statements in support of his positions.

In writing, as in speaking, he was forcible and argumentative, often denunciatory, and at times diffuse, but always evincing a straightforward purpose and will, which did not dally with elegancies of style, but sped to unassailable conclusions. His

published articles were numerous, and appeared in many quarters, often being solicited by editors. It is not necessary here to enumerate them, but they came out in the *London Lancet*, the *British Medical Journal*, and other magazines in England, as well as in the *North American Review*, the *Medical Record*, the "Transactions" of the American Medical Association, and many other journals in this country.

As a physician he was facile and skilful in diagnosis and fertile in resources of treatment. As a surgeon he was deft in manipulations and the use of instruments, decisive and unhesitating in urging the necessity of an operation, and indefatigable in its execution. Bold in these as in all matters, he persevered in the cure of a case so long as he thought relief possible; but never flattered patients with false hopes when he thought death inevitable.

Of fine literary tastes, and well-versed in *belles-lettres* and art, he had a wonderfully varied knowledge of bric-à-brac and ceramics, and still more so of sculpture, paintings, etchings, and engravings. He was familiar with the lives and works of the best artists in each department, and his glowing explanations and vivid descriptions of works of art were a delightful treat to those who heard him. He had acquired a private collection of admirable engravings, whose beauties he would enthusiastically point out and dilate upon in showing them.

His love for choice or rare editions of books, costly bindings, and other artistic embellishments, gave him a constant pleasure in all libraries and collections, and he became the possessor of many curious and valuable volumes.

But when at last, in the early summer of 1883, he became aware that a grave disease, whose incurable nature he fully recognized, had fastened itself upon him, and he began to experience the fatigue, the *malaise*, and the prostration attendant upon its strides, he felt his inability to struggle much longer against its power, and took less interest in his favorite studies, and he became at times more irritable and less able to bear the annoyances of medical practice. Yet he fought a brave fight, and to the very end held himself proudly to the duties of his profession. And in the last weeks of his life, to those who had known well that handsome figure and noble presence, it was a sad sight to see him with wan and dejected look, but firm lips and erect form, slowly pacing the few steps that remained between him and the tomb. His was a life in which there was much to criticize, as in whose is there not? but much also to honor, to imitate, and to admire.

J. S.

### INFLUENCES DETERMINING SEX.

PROF. W. K. BROOKS, of the Johns Hopkins University, contributes a paper on this subject to the January number of the *Popular Science Monthly*, in which he discusses the views lately advanced by Carl Düring in some articles on the laws which determine the sex of the embryo in mankind, in animals, and in plants. "From these observations and from many others quoted by Düring," Professor Brooks says, "we may safely conclude that among animals and plants, as well as in mankind,

a favorable environment causes an excess of female births, and an unfavorable environment an excess of male births.

"I have tried to show, in another place, from evidence of another kind, that the female is the conservative factor in reproduction, and that new variations are caused by the influence of the male. While the environment remains favorable no change is needed, but, as the conditions of life become unfavorable, variation becomes necessary to restore the adjustment, and I believe that we have, in Düring's results, an exhibition of one of the most wonderful and far-reaching of all the adaptations of Nature—an adaptation in virtue of which each organism tends to remain stationary as long as no change is needed, and to vary when variation is demanded.

"That this is the true view is shown, I think, by the contrast between domesticated animals and captive animals. The fact that an animal has become domesticated shows that it finds in captivity a favorable environment, and Düring says that domesticated animals are unusually fertile, and that they produce an excess of females. Animals which are kept as captives in menageries and gardens have, as a rule, no fitness for domestication, and their conditions of life are unfavorable. Geoffroy Saint-Hilaire says that individuals born in menageries are usually male, while skins sent to museums are usually female, and that the attempt to domesticate a wild animal increases the number of male births. Düring states that captive birds of prey and carnivorous mammals are very infertile, and that the young are nearly always males."

### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM DECEMBER 27, 1884, TO JANUARY 2, 1885.

McPAILIN, THOMAS A., lieutenant-colonel and assistant medical purveyor, is granted leave of absence for three months, on surgeon's certificate of disability. S. O. 301, A. G. O., December 24, 1884.

GERARD, A. C., captain and assistant surgeon, ordered from Department of the Missouri to the Department of the East. S. O. 304, A. G. O., December 29, 1884.

JOHNSON, BENJ., captain and medical storekeeper, directed, in addition to his present duties, to perform the duties of assistant medical purveyor in New York City. S. O. 301, A. G. O., December 24, 1884.

EWING, CHARLES B., first lieutenant and assistant surgeon (Fort Stanton, New Mexico), granted leave of absence for two months. S. O. 304, A. G. O., December 29, 1884.

APPOINTMENT.—DR. M. F. GAVIN has been appointed surgeon to out-patients at the Boston City Hospital.

DEATH.—In Fall River, January 5, 1885, Andrew Marion William White, M.D., M.M.S.S., aged forty-two years.

### SOCIETY NOTICE.

SEAFORD DISTRICT MEDICAL SOCIETY.—The Section for Clinical Medicine, Pathology, and Hygiene, will meet at 19 Boylston Place on Wednesday, January 14th, at 7.15 o'clock. The election of a chairman for the ensuing year will take place, and the following papers will be presented: Dr. B. O. Kinnear, "Cholera and its Treatment by Dr. John Chapman's Method, with twelve Cases." Dr. W. B. Mackie, "A Case of Typhoid Fever complicated by Intestinal Hemorrhage, Embolism of the Femoral Artery, and Gangrene of the Foot." Dr. F. Minot will open the discussion.

ALBERT N. BLODGETT, Secretary.

## Original Articles.

REMARKS UPON CHRONIC CONTRACTED KIDNEY WITH NORMAL URINE.<sup>1</sup>

INCLUDING ACUTE GOUTY DEMENTIA, WITH A PERFORATING RECTO-VAGINAL ULCER, AND DEATH FROM SUDDEN PULMONIC OEDEMA.

BY H. C. WOOD, M.D.,

*Clinical Professor of Nervous Diseases in the University of Pennsylvania, and Neurologist to the Philadelphia Hospital.*

Mrs. L., whose case forms the basis of the present article, was a very intelligent lady, about forty years of age, the mother of five children, of gouty ancestry. At regular intervals of four years she was accustomed to have very violent acute attacks of gout or rheumatism, associated with great systemic disturbance and depression of spirits. As the last gouty sickness was in the early spring of 1880, she was in the spring of the present year in great fear of another attack, and an attempt was made, under the direction of her medical adviser, Dr. Tomlinson, to ward off such sickness by careful diet and free horseback exercise. For the early notes of her case I am indebted to Dr. Tomlinson. An exposure to cold during the night of April 20th was followed by severe coryza, vague pains, and great hebetude, with a very pronounced desire to sleep. Even when moving about she seemed unable to keep her eyes open. Under treatment she improved temporarily. Dr. Tomlinson writes concerning this period: "I could discover nothing wrong with the urine, which she passed in usual quantity. A week later she began to have difficulty in expressing herself; she would use irrelevant words and then correct herself; her gait also grew uncertain, and in walking she would pitch forward as though she were going to fall. April 28th, Mrs. L.'s mother died; Mrs. L. was greatly shocked, and rapidly became worse; she was greatly depressed, lachrymose, hysterical, had hallucinations, and ceased to recognize those around her. She lost her appetite, and became constipated. The uncertainty of movement now affected the arms, and there was great failure of memory. Her symptoms continually deepened, the speech became more and more incoherent, until it was a confused, senseless jargon. She now refused food, and finally stayed in bed in a state of perpetual stupor. The tongue was heavily coated, the breath very offensive. There was no elevation of temperature, or pains, or local soreness."

I was first called to see Mrs. L. May 8th; I found her in bed in a sort of stupor, out of which she was with difficulty awakened at all. Getting her partially aroused, I ordered the nurse to put on a wrapper; then commanding and leading the patient, succeeded in getting her to the head of the stairs, then downstairs. It was necessary to hold her very forcibly, as every few minutes her knees would seem to give way, and she would "drop" to the floor. All this time she said nothing other than incoherent protestations. When she finally was in the parlor I upbraided her loudly and severely for her dishabille and general appearance. On asking her if she was not ashamed of herself, she said she was, and that

she had better go upstairs and change her clothes. On my acquiescing she stood up, and taking the hand of her nurse walked upstairs, dressed herself with assistance, and came down recognizing people, but saying very little. I left her eating her breakfast. Her urine was examined at this time; it was loaded with uric acid and urates, although she had been eating very little; had a specific gravity of 1024, and contained no tube-casts, and not the faintest trace of albumen.

She came to the city May 11th. She was now completely demented, knowing no one, and not recognizing in any way her surroundings. The pupils were contracted and immobile. She ate no food except milk, which was forcibly given her at regular intervals. Much of the time she lay in a stupor in bed; then she would have spells of wandering restlessness; again distinct maniacal outbreaks accompanied by violence and indecent speech, or sometimes attacks of muttering delirium. The tongue was brown, dry, coated to the last degree. The teeth were loaded with sordes; the breath horribly offensive; the bowels were obstinately constipated. She was treated with purgatives, quinine, chloral, and morphia, when excited.

During these days there was general tenderness, so that whenever she was taken hold of roughly she would scream out, even rousing from a stupor. There was also on movement distinct pain not located in the joints, but seemingly in the muscles. There were very bad hæmorrhoids, and at times the patient lay stupid but moaning, with knees drawn up, as though there was abdominal pain. The pulse was quick, never much under a hundred, small and feeble rather than strong. Her mental condition grew worse, she took no note of anything, had to catheterized, etc.

By May 16th the general tenderness had become very pronounced; the pupils were dilated and movable; the intelligence somewhat improved, in that she began to take notice. Salicylates and digitalis were at this time being used freely. On 17th severe diarrhoea, with involuntary passages, set in; also the pulse altered suddenly its character, becoming excessively irregular, from 110 to 150 per minute, with beats of all sizes and rates, and many complete intermissions. General tenderness very marked. Auscultation of the heart showed the first sound very weak over the right base; at the left apex the first sound was very weak, the second decidedly accentuated. Over the middle cardiac region the sounds were singularly confused, with a peculiar watery and occasionally grating sound "believed to be cardiac friction, but no clear positive to-and-fro friction rale." [Note at the time.] A blister was applied over the head and one over the heart.

May 18th, menstruation had been established; the pulse had become perfectly regular, 100, and the peculiar middle cardiac sound less distinct. Her mental condition so far improved that she indicated when she desired to pass water, but she could not give a coherent answer to the simplest question.

On the twentieth she, when roused, answered simple questions with some rationality. Severe diarrhoea again manifested itself with involuntary passages and lasted many days, indeed off and on

<sup>1</sup> Read before the College of Physicians of Philadelphia, November 5, 1884.

almost to the end; remedies simply kept it in check. There were no maniacal outbreaks, and a slow but progressive improvement in her mental condition began very distinctly directly after the violent diarrhoea of the twentieth. The first change was in the recognition of her husband; then when she had a desire to stool, she would insist on getting out of bed to the commode, although she never said why she got up. Then she resisted food and medicine, clearly because she had a will not to have them. On the morning of the twentieth she took food herself, knew where she was, and wondered greatly as to the way in which she had got there, having no memory of past events.

June 23d it was first noticed that something was wrong with the vaginal discharge, but a vaginal examination failed to detect any abnormality. On the morning of June 25th faeces were plainly passed per vaginam, and there was discovered a perforation of the recto-vaginal wall very low down, sufficiently large to admit easily the whole forefinger into the rectum. The edges were soft and not well defined. There was no hæmorrhage, local swelling, or pain during the formation of this opening, and it was not distinctly sore.

The mental condition of Mrs. L. continued to improve until about the first of June. At the same time her tongue cleaned and her breath became sweet. June 1st she was entirely rational, recognized her surroundings and friends, servants, etc., in their proper relations. She spoke very sensibly about her own illness. The memory was very much improved, but by no means normal, and there was an absolute lack of power of mental exertion; but the only thing a casual observer would have noted as peculiar was the character of her voice, which remained very unnatural.

The first indication of a relapse occurred about the first of June in a renewed coating of the tongue; then she began to talk irrationally at night, and her memory rapidly to fail. Then a tendency to drop or elide words from her sentences came on and was very pronounced. Her talk in the night began to be irrational and incoherent. At times she was quiet during the day, and at other times very restless. At night she was very wakeful and restless, getting out of bed, wandering about rooms, etc. Much of the time she had an almost uncontrollable desire to pick at her nose and genitals; some days she refused food, others took it. The pulse ranged from 100 to 120, and her physical strength distinctly increased.

From this time onward her mental state deteriorated rather than ameliorated. She lost power of knowing things about her, although she still recognized her husband; the memory was entirely lost; in a word, she was in a condition of almost complete dementia. July 18th the breathing became suddenly accelerated, and some fine subcrepitant râles were heard posteriorly; on the morning of eighteenth her breathing grew much worse; the whole upper lobe of right lung was full of very fine crepitation, the left lung also containing râles. This continued for two days with some slight dulness of percussion on left apex, and then gradually subsided. Some days after this she had an equally sudden attack of oedema of the feet. June 21th

she was taken about 11 p. m. with violent dyspnoea accompanied by fine crepitation anteriorly and superiorly in both lungs, and almost complete absence of breath-sounds over the posterior lobes. The dyspnoea steadily increased and she died asphyxiated after twenty-four hours of straggled.

*Autopsy.*—Kidneys large, plainly in the early stage of chronic interstitial nephritis. Other abdominal organs normal. Heart somewhat hypertrophied; valves normal. Much excess of fluid in pericardium, but no exuded lymph. Lungs highly oedematous; considerable peritoneal as well as pleural serous effusion.

*Brain.*—Basilar arteries; walls very much thickened, sufficiently so to distinctly interfere with lumen; smaller arteries also showing signs of similar endarteritis; the upper and to some extent the basal sub-membranous spaces everywhere distended with exuded fluid; fine vessels of the membrane somewhat congested; a very little lymph in some spots in the membranes. Brain substance very anæmic; the convolutions appeared shrunken; consistence normal, no spots of softening or microscopic changes to be detected; microscopical examination of the convolutions failed to demonstrate anything abnormal, although the cells were perhaps more granular than normal.

There are certain points about this very remarkable case to which it may be worth while to direct the attention. The cause of the dementia cannot positively be asserted; but I am very strongly inclined that it was, at least in part, due to gouty irritation.

It seems to me well established that gout is capable of causing almost every form of insanity; indeed, insanity is only an increase of the mental conditions frequently seen in lithæmia. Carrol in 1859 said: "Gouty mania is occasionally seen," and in 1875 Dr. P. Berthier (*Des Névroses Diathésiques*, Paris) published a collection of forty-six cases of nervous disease attributable to gout; one, hallucinations; one, migraine; four, tetanus; three, chorea; one, hypochondria; seven, epilepsy; one, paralysis, and twenty-six of mental affection including in these dementia, melancholia with stupor, mania. Although in some of these cases the evidence is not at all positive that gout was the *materies morbi*, yet in others the relation seems to have been clearly made out.

In his paper before the International Congress of London (vol. iii. 640), Dr. Raynor supported the following conclusions:—

1. Protracted gouty toxæmia when not very intense usually results in sensory hallucinations or melancholia.
2. Sudden and intense toxæmia results in mania or epilepsy.
3. Intense and protracted toxæmia usually results in general paralysis.
4. If there be a tendency to vascular degeneration from plumbism, alcoholism, etc., varying degrees of dementia are produced.

In the discussion which followed the reading of Dr. Raynor's paper, Drs. Savage and Crichton Browne, of London, both expressed the belief that gout does cause insanity, the latter, however, quali-

lying by the statement — only where there is hereditary predisposition to insanity.

Further proof of the connection between gout and insanity may be found in the Paris Thesis of M. Belliard (1882, No. 269), in which are detailed various cases.

The facts that in Mrs. L. the attack was at the time when an explosion of gout was to be expected, that in all her previous attacks mental depression was a distinct feature, that her urine was loaded with lithates, although she was taking very little food, and that there was widespread exquisite tenderness and soreness to movement with febrile reaction, appear to establish a gouty aetiology. The contraction of the lumen of the basilar arteries was seemingly sufficient to check the freedom of blood-supply to the brain. Brain anaemia certainly existed, as was proven by the autopsy, and no doubt it aided in causing mental weakness.

It is certainly worthy of remark as confirmatory of the generalizations made by Dr. Raynor that the type of mental disturbance exactly corresponded with his conclusions. There was a pronounced tendency to vascular degenerations, and the mental disturbance partook of the nature of dementia.

Passing from the discussion of the aetiology of the case, we note the rapid formation of a recto-vaginal circular ulcer as most extraordinary; its occurrence was entirely spontaneous. It seems to resemble in its nervous pathology the rapid eschars which sometimes form upon the buttock and extremities in severe myelitis, or perhaps even more closely the so-called perforating ulcer of the foot.

The temperature sheet of this patient was remarkable owing to the differences between the two axillae; although, as the autopsy showed, there was no focal brain lesion to account for such difference.

Irregularities of local temperature are well known to occur in focal diseases of the brain, and the temperature in the two axillae in the present case was first tested for diagnostic purposes. The result shows that we may have such irregularities of temperature when there is no local lesion. In a case now under my care at the Philadelphia Hospital believed to be suffering from an acute myelitis, the temperature for many days varied in the two axillae from 0.2° F. to 1.5° F. To my mind it is evident that we need careful bilateral studies of temperatures in various diseases.

The point to which I want to direct especial attention, however, is that the urine was examined various times by Dr. Tomlinson without his finding any evidence of contracted kidney, although such lesion existed. My first glance at the patient made me think that she had chronic Bright's disease, but a very careful examination of the chemical reactions, the specific gravity, and the microscopic deposits of the urine so entirely failed to justify any suspicion that I was entirely misled in this feature of the case. I should here state that my own examinations of the renal secretion were so entirely in accord with the statement of Dr. Tomlinson, that they were not, as they ought to have been, repeated upon various specimens of the urine. As already stated, the aspect of Mrs. L. suggested the existence of chronically contracted kidney, but there was no increased arterial tension, the heart's action whilst she was under my

care being uniformly feeble. It is many years since I ceased putting confidence in the absence of albumen as being of much value in disproving the existence of contracted kidney, but I have hitherto believed that reliance could be placed upon the specific gravity of the urine. The importance of examining the specific gravity of the urine cannot be overestimated; and the import of a persistent specific gravity of 1010 or under can scarcely be mistaken; but in addition to the case just detailed the following is of great interest as indicating that normal urine may accompany a fatally diseased kidney.

Mrs. —, aged fifty-eight, the mother of two healthy children, consulted me in the month of April, 1883, on account of certain spells which afflicted her. The history she and her daughter gave was in brief as follows: the attacks first began in 1876 about the time she ceased menstruating, and had continued ever since; they always came on when the stomach was empty and were sure to happen if at any time during the day she was more than three hours without food, also if she does not get breakfast upon rising she is sure to have a seizure; excessive fatigue increases the tendency to attacks. The spell commences with extreme pallor of face and dark rings under her eyes; if walking her gait becomes very slow, if talking her speech slackens and then ceases; she looks around in a dazed bewildered manner, but does not fall, and is not convulsed at all; she does not become completely unconscious, but does not know where she is or what is going on about her; if a mouthful or two of food be forced down her she arouses immediately, but has no memory of what has occurred during the spell. A careful examination of Mrs. — resulted in complete negations so far as organic disease was concerned. The urine was normal; there was no failure of mental power, choked disk, palsy, headache, or other local symptom discoverable, and I finally settled down to the diagnosis of gastric vertigo. Under appropriate treatment the patient improved, and I saw her at my office for the last time June 4, 1883.

In April, 1884, I was hastily summoned to her bedside, and found her comatose, with a history of distinct convulsions, which were said to have been diagnosed as hysterical by a neighboring practitioner, who, I was also told, after examination of the urine had stated positively there was no disease of the kidneys. On post-mortem examination the brain was found normal, but the kidneys presented the gross appearances of advanced contracted kidney; and careful microscopic examination by Dr. G. A. Piersoll proved that the condition of the organ was as it appeared.

A second case bearing upon the matter in hand is that of —

Mrs. I. W. T., a large, stout woman, who came to my office early last March on account of failing eyesight. Her appearance and description of her symptoms led me to think that she had albuminuric retinitis, but without any examination I sent her to Dr. Harlan, who reported that she had unmistakable albuminuric retinitis, and that no local treatment would be of service.

Her urine had, the day of her return to me, a

specific gravity of 1020, and with the nitric acid gravity test yielded no cloud, or one so faint that I could not be sure that it existed, and noted, "believed to have a trace of albumen." According to her estimate, she was passing two and one-quarter pints a day.

*April 3d.* She passed three and a half pints, having a specific gravity of 1010, and totally free from albumen.

*21st.* Urine three pints, specific gravity 1015; no albumen.

The symptom of increased arterial pressure and cardiac hypertrophy, upon the diagnostic value of which stress has been laid, afforded in the group of cases here narrated no aid. The patients were all large, stout, middle-aged, married women, with full blunts, making the recognition of a slight degree of hypertrophy exceedingly difficult, and the circulation in the two more serious cases was certainly enfeebled.

The practical conclusion to be drawn from these cases is that reliance cannot be placed upon a single examination of the urine, but that in any doubtful case of chronic disease it is our duty to examine the renal secretion repeatedly, noting whether albumen appears after a heavy meal of flesh, and whether the urine of abstinence is of abnormally low specific gravity. I have seen patients who certainly did not have Bright's disease, but in whom an irritant drug or an alcoholic excess would produce albuminuria. It is to my mind very probable that such people will eventually develop renal disease. At any rate these cases have suggested to me that possibly as we employ purgatives to make a so-called therapeutic test in a case of suspected typhoid fever so we might use cantharides, turpentine, or other irritant drug in a case of suspected Bright's disease. If on trial it should be found that a slight irritation would seriously affect the urine, the case should be looked upon with the greatest suspicion.

## CONGENITAL PHIMOSIS AND ITS CONSEQUENCES.

BY HORACE G. WETHERILL, OF TRUSTON, N. J.

CONGENITAL phimosis is a malformation not uncommon in male children otherwise perfectly formed, and is too frequently regarded as unimportant, and neglected because, as sometimes happens, it gives no immediate inconvenience; yet it is often accompanied or followed by diseases, general and local, for which it, and it alone, is entirely responsible, and which are not infrequently very serious in their consequences.

That this condition is not discovered till some malady is established, that its pernicious influence is not properly appreciated, and that means to correct it are not adopted, or are postponed too long, are evident facts, and it is to this neglect or procrastination on the part of the parents or family physician that many distressing cases of chronic vesical or renal trouble are due, and from which many otherwise healthy nervous systems are directly or indirectly ruined, to the end of destroying the com-

fort of the individual and his family, and sometimes making it necessary that he should spend the remainder of his life in an asylum.

My object in preparing this paper is to renew the interest of those who may meet with it in this apparently trivial matter, and more especially to call attention to some of the nervous conditions induced by it; but to show it a subject worthy the attention I give it, and the importance I attach to it, it will not be amiss to call up some of the severe local diseases to which we know it may give rise, and which are not infrequently forerunners of the disturbance of the nerve centres, which is more properly my theme.

Sometimes this elongation of the prepuce and contraction of its mucous lining is so marked at birth that it nearly or quite prevents a free evacuation of the bladder; the urine, passing freely through the urethra, is obstructed by this contraction, accumulates about the glans penis, and, as I have seen in one or two instances, distends the elongated foreskin to the size of a walnut, which distension is only relieved by this accumulation dribbling away or by its being slowly and painfully ejaculated by powerful and spasmodic contractions of the bladder and abdominal walls. The child affected in this way is often wet, and will almost always cry out with pain when urinating, for aside from the difficulty of evacuation the mucous lining and glans become inflamed and excoriated very soon, and if the prepuce is not already tightly constricted it soon becomes so, and increases the difficulty.

The effects of an obstruction of this kind are evident to every physician, for it is quite as potent in causing inflammatory action in the deeper urinary tracts as a urethral stricture could be, and urethritis, prostatitis, cystitis, and sacculated bladder directly result, and it may even extend beyond the urethra and establish in the kidneys themselves chronic and incurable progressive disease.

This is a serious train of secondaries, and should alarm all to an extent that none of these cases should escape observation and correction; but when we know the bad habits and line of dangerous nervous diseases which are directly or indirectly traceable to this trivial cause, and which could be so easily averted, it becomes even more important that it should not be overlooked.

As a sort of text from which to make deductions it will not be amiss to relate a few points from a case which I have had for some time under observation, which illustrates very well the local and general trouble which a congenital phimosis may set up.

The boy was received into the asylum on October 25, 1882, was removed by his father on March 16, 1883, and readmitted on May 13, 1884, being now under my care. He is aged thirteen years, said to have been deranged nearly five years, and has had epileptic attacks since he was six years old, and is believed to have had no injury or accident which could in any way account for his condition. He has always "wet himself," and cried with pain when urinating. He has not slept well, of course, and has now frequent short epileptic attacks. On examination, he was found to have a tightly contracted prepuce,

which obstructed the free passage of the urine; firm adhesions were present between the glans and foreskin, and the meatus was inflamed and gummed together with a viscid mucus.

On June 21, 1884, he was etherized, the adhesions broken up, and the elongated prepuce amputated and retracted. A large accumulation of hardened and stinking smegma was found lodged back of the corona glandis, and the whole mucous membrane had an inflamed and irritated look. His urine on examination was found to be turbid and ammoniacal, and evidently issued from a chronically inflamed bladder; it was of normal specific gravity, however (1015), and free from albumen or sugar.

There is no history of hereditary tendency to epilepsy or to insanity, and no cause could be given by his family why he should be a victim to this malady.

Now, to me it is evident that this condition of phymosis in his case is responsible for his impaired physical and mental condition, and also for his epilepsy.

The line of thought followed out to this end is briefly this: When born he was, to all appearances, a strong and healthy child, but as he grew older he was noticed to have some urinary trouble. His phymosis is evidently congenital. He presumably had, even at this early day, some obstruction to the free flow of his urine, and so firm was his constriction it could not do otherwise than accumulate and distend the foreskin. He then backed up through the urethra and retained in the bladder in spite of strong efforts at expulsion by the bladder and abdominal walls.

From this the road is straight to cystitis, and sacculated and hypertrophied bladder, which is still remaining and is still distressing him.

He loses his natural sleep from pain and the necessity to rid the irritated bladder of an ammoniacal and irritating urine, is constantly wet, and in a frequent condition of sexual orgasm, and, in fact, is the victim of a perpetual irritation upon and in a set of nerves we know to be intimately connected in their physiological and pathological relations with spinal and cerebral functions and disorders, and to the irritability of which we trace many of our cases of neurasthenia, hysteria, etc., in females, and toward which we may well look in seeking a cause for epilepsy in both sexes. He fails in bodily health and vigor, becomes anemic and dull, and, as before said, when six years old, becomes an epileptic without other assignable cause. The inference is plain: the cause of his epilepsy, idioey, and physical breakdown, is primarily only a congenital phymosis.

It may be said this is a rare case, but it is so only in being an extreme one; it has many minor parallels, the unfortunate followings of which are serious but perhaps only delayed.

What can be hoped for from the operation done upon him? Very little aside from the relief of the local discomfort to which he has been so long a victim, and even that, I fear, cannot be entirely remedied, for in an examination made July 2d he was found to have his urinary meatus much inflamed, and gummed together with a sticky, viscid mucus, and a prostate gland so much enlarged

and hypertrophied as to obstruct the passage of a number five steel sound, showing a prostatitis and prostaticorrhea of no small degree. It is, however, but just that he should be placed under the most favorable circumstances for recovery, and particularly so when it involves only so trivial an operation. "The epileptic habit" (as it is called), once established, and long maintained, is seldom broken by the simple removal of a peripheral cause, as the disease induces changes in the nerve centres and membranes which the removal of the primary cause (if distal) cannot effect.

A very long prepuce, even free from constriction, I should regard as a malformation and advise its amputation. It interferes with cleanliness and induces sexual orgasm in very young children, attracting attention to the penis at a time when they should know it, simply as a urinary appendage, without other function, and is doubtless instrumental in making onanists.

Echeverria, in his famous work on epilepsy, says: "Congenital phymosis, in the case of males, renders them specially prone to onanism. This malformation is not necessarily incompatible with health, though it may become a frequent source of troublesome local and general derangement."

Althaus, in an article in *The Lancet* of February 16, 1867, upon "The relation of phymosis to epilepsy," speaks of meeting with the malformation in eleven out of twenty-five consecutive male cases of epilepsy, admitted at the London Infirmary for Epileptics and Paralytics (nearly 40 per cent.).

Echeverria did not find so great a proportion, and in my own investigations among the epileptics in the New Jersey State Lunatic Asylum a smaller proportion was also found (36.5 per cent.).

Thirty-three male epileptics are at present (July 3d) in the institution, and out of that number twelve were found to have phymosis and ten elongated foreskins to an extent which might be mischievous. Twenty-one of these men are known to be, or admit having been, habitual onanists, and the actual number addicted to the habit is probably much larger.

It would not be proper to infer that this habit has, in all these cases, arisen from the malformation, for no doubt in some cases the elongation may have been induced by a long continuance of the practice, and in the same way we know it to be true that the practice is often a result of mental disturbance and consequent abandon. Still in many of these cases we know that the phymosis is congenital and responsible wholly, or in part, for the vice.

As to the potency of masturbation in the induction of mental derangement and causation of epilepsy, we have many celebrated authorities who set forth in their strongest possible words the great influence they believe it to have in causing them. Marshall Hall, Brown-Séquard, Van der Kolk, Echeverria, Maudsley, and Sheppard, agree that "epileptic attacks, like every reflex or direct action of the spinal system, are always excited"; "that epileptiform convulsions may be constant consequences of slight irritations upon certain nerves," and that specially is a continued spinal irritation (like that present in the class of cases we are considering) likely to be followed by the kinds of

disease now common in our overcrowded asylums and homes for the feeble-minded.

There is a peculiar form of melancholia common in asylums, and recognized and described by nearly all authorities upon psychology, which has its origin in a long-continued habit of masturbating. In looking into the matter as bearing upon this question of phymosis, I find the greater number of such cases with which I have met have either a complete phymosis, or such a long prepuce, as in my judgment may have interfered in early youth with cleanliness, physical and moral.

The solitary vice soon leads to a desire to be alone at all times; the victim becomes depressed, and, as Van der Kolk says: "In a word, the depressed tone of mind here passes over into religious melancholia; all afflictions have a religious color." "This peculiarity I have so often and constantly noticed that I venture to express my conviction that we should rarely err if in a case of religious melancholy we assumed the sexual apparatus to be implicated, either through onanism or through other causes."

In examining the works of many of the best authors of the later days, I find more or less a common expression of opinion in relation to this matter, which my own experience verifies, as it is in general about this. That many forms of mental derangement from mania to dementia may be caused by habitual onanism, and that a large proportion of the epileptic and melancholic cases we find in our asylums are results of some sexual irregularities.

That phymosis (or great elongation of the prepuce even) induces a desire to onanize, I regard as proven and axiomatic; so we can easily trace many of these various maladies to a very easily avoided cause.

To correct a phymosis, or amputate a long foreskin in infancy, is a simple operation, done without risk daily by men without medical education, as a religious office, and in obedience to the Mosaic law. It should not be omitted by any, where necessary as a wholesome and cleanly measure.

Moses, if not inspired, had some very good notions regarding wholesome food and hygiene in general, and the so-called Mosaic laws prohibit many things besides pork, which modern science has shown we are better without, and directs many things which we of this enlightened age would find advantageous and wholesome; and this office of circumcision is not the least important of them all.

There is one more point worth considering in this connection, and it is this: circumcision materially decreases the risk of contracting venereal diseases, as where impure connection is had; not so good protection is afforded the specific virus and a much less liability to absorption is present, and in this age of promiscuous and free adultery, and prevalence of these loathsome maladies, all will admit it to be important that we do what we can to prevent what it is always troublesome and sometimes impossible for us to cure.

Note of case made August 4, 1884.

From the time this patient was operated on (June 21st) until July 3d, there was very little change in his general condition. He continued having many

short and not severe epileptic attacks, varying in number from twenty-three to three or four in twenty-four hours, but on no day being entirely without them. During this time the incisions healed nicely, without hindrance or accident, and some improvement was made in the condition of the bladder, as evidenced in a better control of its contents; the sexual orgasm was not so annoying, and his nights were more comfortably and quietly spent.

On July 3d he had a chill, followed by considerable fever, refused food, and was evidently very ill, the cause of which was apparent on the next day in an attack of erysipelas of the face, which soon became very severe, but ran the usual course, and was over in about two weeks; he then became much brighter and more vigorous than he had been for many months, and continues up to this time in an improved condition. During the time from July 3d to July 26th he had no epileptic seizures whatever (an entirely new state of affairs), as at no time during his previous stay in the house had he been more than two or three days without them, and even now they are much less frequent and severe than formerly, and he has had none up to this writing since August 1st.

Ever since his admission the bromides in various forms and combinations had been used in all available ways, but with no benefit. At the time of the operation they were discontinued, and a stimulating and chalybeate treatment was adopted, which is still continued.

He is now in a much more comfortable condition in respect to his genital irritation, as orgasm is seldom noticed, and he controls his bladder for many hours at a time, and is apparently free from pain during micturition, as he no longer cries out or complains. His progress is very satisfactory, and better than I had looked for, as his case is an unfavorable one of a class in which we are compelled by many failures to hope little from treatment, medical or surgical.

## REPORT ON OTOTOLOGY.

BY H. L. MORSE, M.D.

### TEMPERINING THE MASTOID.

AMONG the papers read before the International Congress of Medical Sciences, last summer, at Copenhagen, was a concise and clear article by Professor Schwartz, of Halle, on the indications and contra-indications for the operation of opening the mastoid process of the temporal bone.<sup>1</sup> He says:—

The operation is indicated:—

(1) In acute inflammation of the process with retention of pus in the osseous cells, if, after the application of antiphlogistics and Wilde's incision, the oedematous swelling, the pain, and the fever still persist.

(2) In chronic inflammation of the process, with subcutaneous or subperiosteal abscess, or with fistula leading into the bone, whenever symptoms of such a character as to render recovery impossible are not at the same time present.

<sup>1</sup> Annales des Maladies de l'Oreille, du Larynx. November, 1884. Tome x., No. 5.

(3) When the surface of the mastoid process being healthy, there is a cholesteatomatous mass, or a collection of pus, in the middle ear, which cannot be removed by the ordinary methods, and symptoms appear which cause one to fear a fatal complication; or if an abscess has formed from congestion in the posterior superior wall of the external auditory canal.

(4) When the mastoid process externally showing no sign of disease, and there being no collection of pus in the middle ear, nevertheless it is the centre and point of departure for severe and persistent pain, to relieve which all other means have been tried and have failed.

The value of the operation is doubtful in cases of incurable middle ear disease which has existed for years, and where there are no indications of inflammation in the mastoid process, nor of retention of pus in the middle ear.

The operation is contra-indicated, when it is certain that metastatic abscesses have already formed, or when positive evidence of a secondary meningitis or abscess of the brain is present.

#### REMARKS.

(1) The operation of laying open the mastoid process is a valuable remedy in the most severe and dangerous of the diseases of the ear.

(2) The danger attending the operation must be considered as trifling when compared with that of the disease which it is intended to cure.

In this connection an analysis of the report of fourteen cases of chiseling of the mastoid process by Dr. Arthur Hartman, of Berlin,<sup>1</sup> will prove of interest. To quote Dr. Hartman's most interesting article:—

"Of the fourteen cases which required the opening of the mastoid, there were four in which the mastoid disease was the direct result of acute inflammation of the middle ear. The outer surface of the mastoid process was sound in two of these four cases at the time of the operation; in the other two, abscesses and fistulas had already developed. In one of the former the suppuration traveled through the inner surface of the mastoid process, as first described by Bezold. The remaining ten cases presented complications of chronic suppuration of the middle ear as follows: Formation of sequestra in four (two adults, two children); one case of formation of polypi in the middle ear and mastoid process, and one case of cholesteatomata in an enlarged mastoid antrum.

"Death resulted in two cases, in one of which facial paralysis and symptoms of meningitis had developed before the operation. In the second case the operation was performed as a last resource, pyæmia and thrombosis being present, so that the prognosis was in the highest degree unfavorable."

Both of these cases would come under that class in which, according to Schwartze, the operation is contra-indicated. Of the other twelve cases, eleven resulted in cures, and one passed out of observation before the wound had entirely healed. After giving the history of each of these fourteen cases, Dr. Hartman calls especial attention to several points, namely: He advises that the incision of the skin

and the opening into the bone should be made at the line of attachment of the auricle, or immediately behind it, on account of the danger of injuring the transverse sinus, if the incision is made more posteriorly.

He says that the transverse sinus not infrequently makes a sharp curve forward toward the posterior wall of the external auditory canal, and to guard against such cases he makes his incision at the line of the attachment of the auricle. To avoid penetrating into the middle cranial fossa, he does not allow the opening into the bone to extend higher than the level of the upper wall of the external canal. He advocates the use of a chisel instead of a drill or trephine, because with the chisel the bottom of the wound is easily examined during the whole operation, and if one comes upon the sinus he can recognize the danger in time and avoid it, whereas with the drill or trephine the injury to the sinus in these cases is inevitable. The opening in the skin and in the bone should be large enough to allow free inspection of the wound during after-treatment.

Sequestra, cholesteatomatous masses, and granulations, are to be removed at the time of the operation: the latter are best scraped out with a sharp spoon. The wound must be kept open with drainage tubes until the wound cavity has diminished in size concentrically, by the development of sound granulations, and in the meantime all profuse and soft granulations are to be removed by the sharp spoon or cauterized. The wound is to be frequently syringed and dressed with powdered iodoform. He considers this dressing valuable in preventing inflammatory reaction, and in none of the cases reported did inflammatory reaction follow the operation. In most of the cases the pain and other serious symptoms improved immediately and strikingly after the mastoid process was opened.

#### A case of

#### ROUND-CELLED SARCOMA OF THE EAR

is reported in the *Archives of Otolaryngology*,<sup>2</sup> with a wood-cut.

"The case is of interest from the rarity of such growths in this situation," from the size to which the tumor attained, "eight inches in length, six in breadth, and four in thickness over the mastoid; in addition, it extended below and in front of the auricle." . . . "The patient died from exhaustion." No autopsy could be obtained, but microscopic examination of a portion of the tumor showed it to be "a sarcoma of the round-cell variety."

#### AURAL SYMPTOMS OCCURRING IN HYSTERIA,<sup>3</sup>

and the hysterical element in aural disease, with a report of two cases.

"There are unquestionably numerous cases in which the subjective symptoms of an existing aural disease are increased to an extent which gives them undue importance in the mind of the practitioner by the coexistence of functional cerebral disease evidencing itself in the train of symptoms to which collectively we give the name of hysteria." . . . "It is

<sup>1</sup> *Archives of Otolaryngology*, vol. XIII., No. 2.

<sup>2</sup> *Archives of Otolaryngology*, vol. XIII., No. 2. J. Orin Green, M.D.

<sup>3</sup> *Annales des Maladies de l'Oreille, du Larynx, et de la Trachée*, tome V., No. 1. C. J. Blake, M.D., and G. L. Walton, M.D.

also true, since the ear is most intimately connected with the central nervous system, that it may play an important part as an aetiological factor in nervous disease, and for this reason a careful consideration of its symptoms in disease and an investigation into its condition, even when no marked symptoms of aural disease are present, are of great importance to the neurologist." . . . "Of the two cases here reported, the first illustrates the extent to which an aural disease, severe in its objective as well as its subjective symptoms, may be simulated in a hysterical patient; the second the influence which an existing aural disease of comparatively mild character may have in originating marked hysterical symptoms in a case already of hysterical tendency, and, reflexly, of exciting symptoms leading to the apprehension of a graver aural disease."

The aural symptoms, which in the first case simulated mastoid disease, and later on a possible extension of the inflammation to the brain, were as follows: "The head was held stilly to one side, the expression was one of pain and anxiety, there were slight redness and swelling behind the left ear." . . . "The patient complained of severe pain in the left mastoid and temporal regions, and of great tenderness over the whole surface of the mastoid upon even slight pressure. The external canal was normal, but both membrane tympani, while normal in general color, transparency, and light reflex, showed marked congestion of the manubrial plexus; there was also a general congestion of the tympanic mucous membrane as seen through the transparent membrane tympani."

About two months after the first examination of the patient she was found "lying on the floor unconscious, with cold extremities and very feeble pulse; consciousness soon partially returned, and there was then found an incomplete left hemiplegia." Still later on she complained of intense nausea and vertigo on raising her head, pain in the ear radiating to the vertex, and tinnitus aurium, both nausea and pain being increased by pressure over the mastoid region. Although the case presented so many symptoms which seemed to point to aural disease, the diagnosis of hysteria was made from the presence of many other symptoms of a more clearly hysterical character than those given above, and the subsequent history of the case proved that the diagnosis made was correct.

In the second case the picture presented to the aurist when called in consultation was the following:—

"The patient, who is extremely emaciated, lies on her back, seemingly unconscious of her surroundings, rolling occasionally from side to side slowly, with arms extended above the head, sometimes rising on hands and knees without special rigidity. There is no indication of great pain. The patient takes no notice when first addressed, but responds dreamily to repeated questioning. After urging opens the eyes, protrudes the tongue somewhat, and finally drinks with difficulty. The pupils are alike, and respond normally to light. No strabismus exists or paralysis, either ocular or elsewhere. The tendon reflex is greatly exaggerated on both sides. Pressure over the ovarian region causes apparent distress, while pressure over the mastoid and tem-

poral regions causes none. No difference of sensation is discoverable on the two sides of the body, the prick of a pin being evidently everywhere disagreeable. There is no deviation of the tongue. There is no projection of the auricle, nor is there swelling over the mastoid region. The temperature is normal, the pulse 120, the respiration 30. Neither vision nor hearing can be accurately tested, but both the voice and the watch-tick are heard on both sides."

The exciting cause for these serious and alarming symptoms was an inflammation of the middle ear, giving rise to a serous effusion, for which the membrane tympani was perforated by the attending physician; this was followed by a profuse sero-purulent discharge, for which a drainage wick was used. Three days after the consultation the patient gave evidence of the hysterical nature of many of her symptoms by going into hysterical convulsions, grimaces, fits of laughter, and crying. The stupor diminished, the strength improved. At the same time the purulent discharge from the ear steadily diminished. At the time of the consultation no treatment was advised beyond that required locally for the purulent inflammation of the middle ear, "but the importance of abundant nourishment by artificial means, if necessary, was strongly urged." . . . "The interesting feature of this case was that, while a slight hysterical tendency" (a slight irritability since the birth of a child two years before) "perhaps existed before the onset of aural disease, this disease was itself apparently the exciting cause of the severe hysterical symptoms here reported, and which gave rise to the suspicion of meningeal trouble."

## Therapeutic Memoranda.

### COCAINE AND CURETTE.

BY G. H. FILDEN, M.D.

The patient presented a superficial epitheliomatous ulceration of the temporal region, just in front of the ear. The ulcer had existed for three years, and was about the size and shape of a ten-cent silver piece. The subcutaneous tissues were involved, the borders of the ulcer supple, and its base was composed of soft, pale, and flabby granulations. Four drops of a four per cent. solution of muriate of cocaine were placed upon the ulcer, which held the fluid like a little cup, the patient's head resting upon a pillow. During the next quarter of an hour two more applications were made, each of the same quantity, and the diseased tissue was then thoroughly scraped out with a sharp spoon, the patient suffering no pain whatever. When the scraping was finished a fourth application of four drops of the solution was made, and a few minutes afterward the wound was vigorously cauterized with a stick of  $\text{AgNO}_3$ , the insensibility to pain being no less marked than before.

The application of the cocaine seemed to have a slight tendency to check the bleeding, but not to any marked degree, and the wound healed quickly and without disturbance of any kind.

## Reports of Societies.

### SUFFOLK DISTRICT MEDICAL SOCIETY.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

ROBERT B. DIXON, M.D., SECRETARY.

NOVEMBER 19, 1884. DR. JAMES R. CHADWICK in the chair.

DR. STEPHEN W. DRIVER, of Cambridge, by invitation of the Society, read a paper entitled

#### AN ANALYSIS OF ONE THOUSAND SUCCESSIVE OBSTETRICAL CASES.

DR. HARLOW remarked that, in cases where the head had ceased to advance, some of the older authorities recommended waiting for four hours before applying the forceps, but more recently others said wait but two hours; he would like know Dr. Driver's rule in such cases.

DR. DRIVER replied that with his earlier cases he was undecided just how and when to act, but later, and at the present time, he considered that the condition of the patient would not warrant his interfering unless he was perfectly satisfied that all progress had ceased. It might take one half-hour to decide this point.

DR. HARLOW mentioned that he had observed in several instances that progress had ceased for two or three hours, and then returned and the labor was terminated without any interference being necessary.

DR. DRIVER said in cases where the natural powers could not finish the labor, delay involved danger to the child, which might be saved by the use of the forceps. There is no harm in using the forceps even when the labor is easy.

DR. FRANCIS MINOT asked if the reader had observed any relation between the use of forceps and post-partum hæmorrhage.

DR. DRIVER replied that, with the exception of one case in which he had used long forceps, the woman being in a state of exhaustion at the time, he had noticed no relation whatsoever. He also said that he preferred to, and generally did, use the forceps without administering ether, and he considered that the non-use of ether had much to do in avoiding hæmorrhage.

DR. MINOT said the question whether the use of ether in forceps cases had any influence in causing post-partum hæmorrhage was one of great importance, and difficult to settle. The patient is usually already more or less exhausted, and therefore predisposed to bleed. The comparison of a large number of observations would be necessary to determine the point. One thing he had always considered remarkable—the rarity of death from post-partum hæmorrhage. Dr. Driver did not have a single fatal case. Dr. Minot had had but one death from this cause in the course of his obstetrical practice, which, however, was not large. He had come to the conclusion that recovery was, in most cases, a natural result, and less often due to the treatment employed than was generally believed. Dr. Minot then asked if Dr. Driver had made any examination after delivery to determine the condition of the cervix.

DR. DRIVER replied that he had not, but when attending women a second time he had failed to find any lacerations.

DR. MINOT asked Dr. Driver his method of dealing with the placenta.

DR. DRIVER said that he always had the nurse follow the uterus down firmly. After the birth of the child he waits for two good and firm contractions, then grasps the uterus and stimulates it to contract, and he has never failed to find an edge of the placenta protruding unless there was some morbid condition existing. He never pulls the cord, nor delays more than ten to fifteen minutes before expelling the placenta.

DR. REYNOLDS remarked that the fourteen instances of high application of the forceps which had been described seemed to him an extremely uncommon use of these instruments. What was the average duration of these operations?

DR. DRIVER replied that ordinarily he was from one half to three fourths of an hour in high cases. He imitated nature as much as possible, and never hurried unless there was some necessity for so doing, as in a case where convulsions were present.

DR. REYNOLDS said that such an employment of forceps was not in accordance with his opinions or with his habit. He thought he ought not to detain the Society by bringing up the much debated question of the grounds of choice between version and forceps in operative obstetrics. He would venture the remark that partisans on either side have not infrequently based their preferences upon their entire list of cases. No valuable conclusions are reached if this be done. Under conditions wholly favorable version becomes delightfully easy,—its results most admirable. Quite as much can be urged in praise of the every-day applications of forceps. We approach the real question, when we place side by side the truly hazardous cases of difficult extraction following version and forceps deliveries, like those under consideration, where both the time required and the otherwise formidable character of the procedure put two lives in peril.

The fact that anaesthesia, when in operative obstetrics it is necessarily prolonged to deep unconsciousness, introduces an element of danger should not make us loath to acknowledge that in ordinary childbirth its rational use is an inestimable comfort. Thus employed it presents absolutely no drawback. The continued endurance of suffering induces more surely than all other causes combined exhaustion of nervous supply, consequent uterine relaxation, and the tendency to alarming loss of blood. To abolish this suffering with its many attendant risks is the one great service of anaesthetics. It is true that even moderate anaesthesia rarely fails to lengthen the duration of labor; but to a patient from whom the remedy has taken all intelligent appreciation of time the added hour or half-hour is of no moment. Rare instances are observed in which ether does its very best work by making women who, under agonizing pain long continued have grown unmanageable, tractable and helpful. In an opposite, very small, minority of patients anaesthesia arrests uterine contraction. When this

occurs the one indication for the remedy is gone. It cannot then safely be continued.

He who withholds from women in labor a blessing so great as this, who implies that the resort to it is unsafe and even dangerous, ought to be held to the most convincing proof of his assertions, at the peril of being arraigned as both selfish and cruel.

Dr. BOWDITCH said that many years ago, when in general practice, he had met with two cases of fatal umbilical hæmorrhage. They occurred in the deliveries of a perfectly healthy lady, and at intervals of seven years. She had several other but healthy children, and none have shown this hæmorrhagic tendency, nor has it occurred in her descendants of the next generation.

In both of the cases alluded to, there was a slight oozing around the umbilical remains before they finally came off on the third and fifth days, leaving the navel and parts around them apparently sound. In the first case, on the fifteenth day after delivery, there having been only a slight oozing previously, and easily checked, the oozing was renewed. In spite of astringents, nitrate of silver, and finally a surgical operation by Dr. George Hayward, by the transfixing of a circle of healthy skin beyond the umbilicus, and ligature of the whole mass, the child died on the twentieth day from birth, the sixth from the time the hæmorrhagic oozing became permanent.

The second child, seven years afterward, went through a similar course with death on the thirteenth day of life and the third day of hæmorrhage. Dr. Hayward finally used the actual cautery after all other remedies had proved of no avail. Hepatic disease was found at the autopsy.<sup>1</sup> Dr. Bowditch then asked the reader if he used any treatment for convulsions besides forceps.

Dr. DRIVER answered that it depended upon the time that he was called to the case. His practice was to empty the uterus. If he had to wait one half-hour or so for instruments or assistance, he was in the habit of giving a small quantity of chloroform. In one case only, which lasted for forty-eight hours after delivery, had he used any medicine. Ether, opium, and the acetate and bromide of potash were given. Both the woman and child lived.

Dr. BOWDITCH mentioned a case of a healthy, strongly built, large young woman, who was very recently confined with her second child. Puerperal convulsions came on, and bromide of potassium was freely used. Death ensued. Dr. Bowditch thought that possibly venesection, to the amount of sixteen or twenty ounces, while it would not have injured one of her form and health, might have saved life. Dr. Bowditch regretted that venesection had not been tried, as he had known of cases of puerperal convulsions, and also of *acute* cardiac and pericardial affections, in which great dyspnea had come on, which were entirely relieved by venesection. Our fathers used venesection immoderately and absurdly, and we, in modern times, are with equal absurdity giving up *wholly* a remedy which, if used properly, is of immense value and power toward saving life.

Dr. BRIDG said he gives either if the patient

demands it. He found that in the first stage if much ether was used the pains stopped, while later it does not interfere with them.

Dr. MARTON spoke of the remarkably low death-rate in Dr. Driver's cases, and then reported the following three cases:—

CASE I.—Mrs. L. Fourth pregnancy. Three hundred days from cessation of last menstrual period she fell in labor, having felt for a week previous as if she was in labor without the real labor pains. She was seen during the forenoon, when an examination showed the os fully dilated, patulous and shortened as usual. The head could be easily felt, but it was not easy to make out and distinguish the sutures; no fontanel was detected. When the uterus contracted the head would move over the pelvis, reminding me of trying to force a croquet ball through a cylinder of less diameter. At 5 o'clock the following morning the pains becoming less frequent and of less force, the os oedematous and the patient much exhausted, after emptying the bladder, I applied long forceps; my brother, Dr. O. H. Marion, assisting. It was with the greatest difficulty the head was delivered, and then not without fracture of one of the frontal bones by compression. The head as a whole, was much distorted. The child lived twenty-four hours. The shock was severe; the patient remaining in a state of collapse several hours. The first urine that was drawn, about twelve hours after delivery, was bloody, suggesting a vesical fistula, which was afterward found to exist. She had a long and tedious convalescence complicated with general pelvic cellulitis, with symptoms of septicæmia. Later when an enema was given to relieve the bowels, water was noticed to flow from the vagina. Suffice it to say she eventually got up and all that could be demonstrated was a lacerated cervix extending above the vaginal junction at the bottom of which was a small opening into the bladder. I might add that this patient in twenty months gave birth to a five months fetus, and again fifteen months later gave birth to a fetus under seven months, which lived and is living to-day. In the following November I was called to

CASE II.—Mrs. M. Multipara. When first seen, at midnight, the os was fully dilated, and the head presenting but not engaged. The fetal heart could not be heard. The antero-posterior diameter was much shortened. Pains continued good, but the head still remained disengaged. At daylight no progress having been made, I applied long forceps but they slipped. I then decided to perform craniotomy, my brother assisting. Braun's instruments were used, and delivery was easily accomplished. The child was estimated to weigh twelve or fourteen pounds. Patient made an uninterrupted recovery, and in nineteen months I again delivered her, under similar circumstances, in the same manner as before, except the forceps. The weight of this child was thirteen pounds.

Following close upon this was

CASE III.—Mrs. D. Multipara. At my first visit I made out, with great difficulty, the os pretty well dilated; the head presenting. The abdomen was pendulous and the pains ineffectual, although the patient was advised to lie upon her back. At

<sup>1</sup> For these cases and a paper on the subject see *Am. Journal Med. Sciences*, Philadelphia, January, 1880.

midnight the patient, as well as myself, being tired out, and there being no one to send for assistance, after an ineffectual attempt to apply forceps, I introduced my hand and produced podalic version, but it was with the greatest difficulty I delivered the head of a twelve-pound still-born child. No anaesthetic was used. Patient made a good recovery, but prolonged somewhat from excessive loss of blood. This patient has since passed through a normal labor under my care, but with a child weighing but eight and three-fourths pounds. In this connection I might refer to a case sent to the Lying-in Hospital, and reported by Dr. Boardman.

Dr. DUNN said that since his first 550 cases, which extended up to January 10, 1882, he had had 260 more, making a total of 810 up to the present time. All of these cases occurred in his own practice with the exception of fifty-two, which he attended for other physicians. A very large percentage of the cases have been normal in almost every condition. Among the abnormalities and accidents were, of breech presentation eight cases; of feet, two; head and funis, three; arm, one; placenta previa (complete), one; (partial), one; face, one; transverse, one; putrid at birth, four; occiput posterior (right or left), eighteen; exhaustion due to excessive use of chloral, by nurse, one; death, one; forceps, ninety-six; version, eight; twins, five; knee, one; resuscitated after an interval of three fourths of an hour, two; after one half-hour, three; thrombus of vulva after forceps, one; excessive oedema of anterior lip, two; primary post-partum hæmorrhage, two; severe secondary hæmorrhage after seven days, one; ante-partum hæmorrhage, three cases: one occurring at four months, one at seven months, and one at eight months. These three patients conceived at term. There was one case of pelvic abscess; one of excessive vomiting, in which it was necessary to induce labor at the eighth month; two cases of phlegmasia alba dolens, and two of adherent placenta. The weight of the smallest infant was two and one-half pounds, and of the largest twelve and one-fourth pounds. Both children are now living. Two children were born with a lower central incisor; one with imperforate anus; one with imperforate anus and absence of the rectum, upon which colotomy was performed; and there was one case of spina bifida. Emphysema of trunk, neck, and face occurred in one case one day after labor.

Dr. C. M. GREEN said it was his firm belief that in a great majority of the cases, in which either the long forceps operation or podalic version must be performed, the latter operation should be elected in the interest of both mother and child. Of course, in certain cases version was contra-indicated; as, for example, in labor with twins, and when the uterus was in a state of tonic contraction. In considering this subject he had reference entirely to those cases in which the head was either above the brim or just within it, and not to cases in which the head was in the cavity and could be reached with the ordinary forceps of Simpson or Braun. He thought the introduction of forceps within the uterus and the extraction of the head through an os not entirely dilated was a serious procedure for both mother and child, especially if there was any disproportion

between the pelvis and the foetal head. Moreover, as long forceps must necessarily be applied with reference to the pelvis and not with reference to the foetal head, it naturally followed that compression exerted in the transverse diameter of the pelvis would cause a corresponding increase in the diameter of the head, which occupied the antero-posterior diameter of the superior strait; since a slight contraction in the superior conjugate constituted in many cases the obstacle to descent, the use of long forceps to overcome that obstacle, whereby the relative disproportion was increased, seemed to him entirely illogical. On the other hand, after podalic version the bimastoid diameter of the after-coming head is substituted for the suboccipito-bregmatic diameter of the fore-coming head, and in this way a head would often pass like a wedge through a contracted conjugate, which could be extracted with long forceps only with great danger of serious injury to the maternal soft parts, and perhaps fatal compression of the foetal head. In performing version the speaker believed it to be very important to fully dilate the os with the fingers before passing the hand into the uterus and attempting extraction; otherwise there may be serious delay to the passage of the head, or a considerable laceration of the cervix. Dr. Green asked the reader if in any of his cases he had observed secondary hæmorrhage from the umbilical cord.

Dr. DRIVER replied, very seldom unless from large, thick cords. He has never lost a child from hæmorrhage. It is his custom to tie the cord three times, and if there should be any hæmorrhage he ties it again. If the cord is large it shrinks within the ligatures. He said he did not agree with Dr. Green regarding the operation of version. He prefers the forceps in utero and above the brim in all except a few cases of irregularly shaped pelvis that some call "the figure of eight" pelvis, some cases of placenta previa, and cross births that cannot be otherwise replaced. He has had two cases of death in children that he considered were due to the grasp of the forceps.

Dr. ROYAL WHITMAN reported the following:—

#### A CASE OF PLACENTA PREVIA: DELIVERY BY VERSION.

On July 18, 1881, I was called to attend my patient, a primipara, thirty-five years of age, who gave the following history: Her last menstrual period had terminated on October 12, 1883, and during the several ensuing weeks she had suffered considerably from nausea and vomiting. She had felt the foetal movements for four months, and during the past few days had had irregular pains, varying in intensity, for several hours each day. On the evening preceding my visit she had the usual pains, which, however, continued during the night, and at two in the morning she had a moderate hæmorrhage, sufficient in amount to saturate several napkins. At five she had a second similar hæmorrhage, and immediately sent for a physician. Examination showed a small amount of clotted blood in the vagina, the os rather high up, of about the size of a quarter-dollar, and on the left side a rounded, slightly projecting mass, evidently the placenta. The position was occiput, right posterior. The

placental souffle was heard with greatest intensity just to the left of the pubes and the fetal heart below and to the left of the umbilicus. The condition of the mother was good. The uterine contractions were weak and rather irregular, coming on at intervals of about ten minutes and were not accompanied by any considerable amount of hemorrhage. Dr. Thorndike was called in consultation, and advised non-interference while the hemorrhage was small in amount, but that the membranes should be ruptured if it increased. Until noon the pains continued weak and irregular. There was no hemorrhage, and the os had dilated little, if at all.

Soon, however, the uterine contractions became more regular and frequent, and were accompanied by a small amount of bleeding, sufficient to saturate one napkin an hour. At five p.m., the os had dilated to about the size of a half-dollar, and the hemorrhage was gradually increasing with the increased force of the uterine contractions, though not considerable in amount. Shortly after the last examination, the patient became very pale, vomited, and exclaimed that she was dying; and on finding a considerable quantity of blood in the bed, I at once gave ether. On removing the mass of clotted blood from the vagina, the os was found to be flaccid and almost completely filled with the partially detached placenta. This was pushed aside, the hand readily introduced and the membranes ruptured. The cord was not pulsating and no uterine contractions were present. The child was easily turned and extracted, the only difficulty being caused by a slight extension of the head, which was remedied by the introduction of a finger into the mouth and pressure on the occiput.

The child was cold, blue, and pulseless, but after some moments of artificial respiration, direct inflation of the lungs and applications of cold douches, began to breathe. Meanwhile subcutaneous injections of brandy were given the mother, and the uterus contracted firmly after the expulsion of the placenta, which followed the delivery of the child.

During the night the mother's pulse was very weak and rapid, from 120 to 140, and she complained of great thirst. Ice-champagne was given, and she slept at intervals. Her recovery was uninterrupted. Catheterization was necessary for a few days. The temperature never rose above 100°, and there was no rupture of the cervix or perineum. The weight of the child, a female, was seven pounds.

There had been no previous hemorrhage.

Dr. VICKERY reported the following case of

#### PLACENTA PREVIA CENTRALIS:—

The patient, aged thirty-eight, and pregnant for the seventh time, had had six normal confinements—except that in her first labor forceps had been used and the perineum moderately torn, the laceration remaining ununited. In this seventh pregnancy there was, at the end of seven months, a slight flow of blood; one month later a more considerable one, and at term a sudden and profuse hemorrhage. Although she had previously engaged a midwife, she now sent for Dr. Roche, of Chambers Street, who made the correct diagnosis, plugged the vagina, and asked Dr. Vickery to see the case in consulta-

tion. The vaginal plug had in some degree checked, but had not controlled, the loss of blood. Dr. Vickery being asked to operate, ether was given, and the hand introduced into the vagina. The os, which was about three inches in diameter, was easily sufficiently dilated to admit detachment of the left edge of the placenta, rupture of the membranes, and immediate turning, upon the left foot. As blood still gushed out with every pain, extraction was proceeded with, and, thanks to the aid of Dr. Roche, successfully terminated. Both the mother and the child, a girl of six or seven pounds weight, survived, and are still doing well after the lapse of ten weeks.

Owing to circumstances beyond the control of the reporter, the only antiseptic precautions previous to delivery consisted in the thorough washing of the hands with soap and hot water. There were no symptoms of infection afterward.

Dr. E. W. WARREN reported

#### TWO CASES OF MISCARRIAGE,

and exhibited the specimens.

Mary T., forty-six years old (began to menstruate at fifteen), has been pregnant sixteen times with easy labors, thirteen of them running to full term, two were miscarriages and the present case. The last confinement occurred a year ago last February, and the last miscarriage over seventeen years ago. She told me that she had considered herself about six months along. All went well till the third month, when she got a fall. This brought on flowing, accompanied by pain and the passing of clots, which confined her to bed for a week. Then all trouble ceased and everything went on well for another three months, when she began to have pains like labor pains, accompanied by some hemorrhage, till on the third day, while trying to lift a washtub, the contents of the uterus was expelled, accompanied by rather severe hemorrhage and some clots. This was controlled by ergot and rest, and three days afterward she was in a very fair condition but feeling rather weak, and there was still a slight oozing of blood. When seen again, two months afterwards, she complained of some pain in the back and bearing-down pains, and said she had what she considered her regular monthly sickness a week before. I had an opportunity to carefully look over herself, husband, and two children, and no sign of syphilis was to be found, but the tubercular trouble was very pronounced in the husband, who since has died of phthisis, and in one child seven years old. Other children had died of tubercular meningitis as far as I could make out from the history. The specimen was two and a half inches long; membranes intact. About one tenth of area was membranous. On opening carefully under water no trace of a fetus could be found; the contents consisting of a bloody fluid. The inner wall was nodular; the nodes being about one fourth of an inch in height and diameter. Microscopical examination showed diffuse blood extravasation in some cases so old that the blood-coloring matter had separated out. There were very few decidual cells left. His opinion of the case is that the extravasation took place at the time of the first accident, and the fetus dying was entirely absorbed before the

expulsion of the sack. Being rather an ignorant woman her dates were probably a month too soon.

In connection with this specimen I show one which Dr. J. R. Chadwick gave me to exhibit at the same time. He received it some years since, from another physician, and without its history. The same condition was present as in the case mentioned, except it was localized, there being four or five pockets three fourths of an inch in diameter filled with coagulated blood. The most interesting part of this specimen is the presence of a fetus one fourth of an inch in length, attached by a cord of about the same length to the walls. The entire sack was about three inches long and showed how it may continue to grow after the death of the fetus.

#### CLINICAL SOCIETY OF THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL.

STATED meeting Saturday, December 20, 1884, Dr. Benjamin F. Dawson, in the chair. Dr. M. Putnam Jacobi opened the discussion upon diphtheria as follows:—

MR. PRESIDENT, —I propose in these remarks chiefly to give an account of the recent experiments which have been made in regard to the parasitic aetiology of diphtheria. That this poison is due to a living organism, there can, says Loeffler, be to-day no doubt; and it is unnecessary to repeat reasons for this doctrine which have been already so often alleged. The question is simply to find and isolate this organism, and then to prove its causal relation to the disease by a demonstration of three fundamental conditions. First, The organism must exist in typical abundance at the seat of the characteristic lesions of the disease. Second, It must be isolated and submitted to a "pure" culture. Third, By inoculation of products of this culture, it must be possible to excite the typical disease in one or more species of animal.

The remark has often been made that an almost irresistible tendency to the acceptance of the "germ" theory of infectious diseases arises from observing how completely it harmonizes with the great doctrine of the universal struggle for existence, which is the philosophical achievement of the nineteenth century. In accordance with that doctrine, one may easily seem to discern the rise and fall of vast empires of micro-organisms intersecting the course of human history as successive epidemics. Thus the flourishing period of one such empire, now extinct, would be represented in the plague of Theueyides. Another empire of infinitesimals appeared to human eyes as the Black Death, which ravaged Europe for three years, and swept off one half of its inhabitants. The migrations of the barbarians are simulated exactly by the migrations of cholera, emerging like them from Asia. Darwin tells of the disappearance of certain breeds of antelopes from the pampas of South America, when a certain minute fly gained the ascendancy in the vital struggle, an insect which was accustomed to lay its eggs in the navel of the superior animal. Human beings disappear as readily before even minuter organisms; the destiny

of either is determined by a question of nutrient soil and of adaptation to it of the larger or smaller species of living things. It is said that Laycock, in 1858, first suggested that a vegetable organism excited diphtheria; but he supposed this unknown plant to be a product of the *oidium albicans*. The majority of observers who have looked for such organisms in diphtheritic membranes have found micrococci in them. Minute micrococci were described in 1867 by Buhl; in 1868 by Hunter and Oertel; by Nassloff and Eberth in 1872; by Rosenbach in 1877; Graham Brown in 1878; and Letzerich in 1880; while in 1882 Wood and Formad found and cultivated numerous micrococci, but considered them to be merely the transformation of the ordinary micrococci of the mouth, from a latent to an active state.

On the other hand Cornil and Ranvier (1881) observed both micrococci and rods in the diphtheritic pseudo-membranes, and Klebs (1883) communicated to the International Congress the description of a species of bacillus, with which Loeffler's most recent researches essentially agree.<sup>1</sup> But in 1881 Talamon created a sensation in France by the alleged discovery of a fungus with a mycelium composed of long tubes mingled with short rods, and also with round or oval spores: whose cultivation and inoculation upon animals, caused death with various lesions. On the other hand, Senator (1872) insisted that the micrococci were accidental complications, foreign organisms, implanting themselves on the favorable soil of diphtheritically inflamed tissues, and that it was on this account that they were found limited to the most superficial part of these, or even of the pseudo-membranes. The most sweepingly negative experiments were made by Satterthwaite and Curtis (1879), who found that inoculation with fragments of diphtheritic membranes yielded such varying results that no positive conclusions could be drawn as to the aetiological relation of the membrane to the disease. Sometimes the inoculated animals remained unaffected; sometimes they presented local inflammations and abscesses; sometimes died with symptoms of general infection, but never with either symptoms or lesions characteristic of diphtheria.

Heubner (1883) published experiments tending to establish the relation to be expected between pseudo-membranes and bacteria which might be present in the circulation. He produced non-specific pseudo-membranes upon the mucosa of the bladder of rabbits by tying a temporary ligature around its neck, so as to completely interrupt the circulation for about two hours. On withdrawing the ligature, the circulation was restored; but the interruption had sufficed to destroy the vitality of the epithelium, which desquamated, and to impair the integrity of the blood-vessels, so that fibrine transuded on the abraded surface, and a pseudo-membrane was formed resembling that of diphtheria in every respect except in the presence of micrococci. The lesion remained local, and the health of the animals scarcely affected. In a second series of experiments at the time the pseudo-membranes began to form, Heubner injected into the jugular vein fluid holding in solution anthrax bacilli. The animals died of anthrax, and at the

<sup>1</sup> Mittheilung aus dem Kaiserl. Gesund. Amte, 1884.

autopsy the pseudo-membranes of the bladder were found infiltrated with the bacilli, which were also present in great abundance in the subjacent blood-vessels.

Heubner concludes that if in diphtheria any micro-organism which our present resources enable us to recognize were really present in the circulation, it would be found in abundance in the blood-vessels subjacent to the pseudo-membranous exudation; whereas none have been found in this locality.

Loeffler sums up the results hitherto obtained from investigations as follows:—

All observers have found bacteria in diphtheritic pseudo-membranes, although many have contented themselves with searching for it by means of the dilaceration method, which prevented the exact relations of the tissues from being ascertained. In the majority of cases the bacteria described have been micrococci, usually in colonies, and these nearly always on the most superficial part of the membrane. Only occasionally have they been found in the lymphatics of the affected parts; still more rarely (Letzerich) in internal organs. To examine these the modern resources of aniline staining, Abbe's condenser, and oil immersion lenses, have, so Loeffler asserts, been only insufficiently employed. Cultures have been made in fluid media, and thus it has been impossible to isolate from each other the different species of bacteria, of which every diphtheritic pseudo-membrane contains several. In the coincident evolution of these different species the physiological action of each becomes neutralized, and even the development of some completely hindered by that of others. This circumstance accounts for the negative or atypical results of inoculation with the products of such fluid cultures; and similarly, for the uncertainties consequent upon inoculation with fragments of the membrane itself, as in the experiments of Satterthwaite and Curtis. The lesions produced by experimental inoculations, among which those obtained by Takamon are among the most celebrated, include hemorrhagic inflammation of muscles, localized edema, serous and hemorrhagic effusions into serous cavities, with reddish-brown hepatization of the lungs, radial keratitis, but neither the pseudo-membranes nor the local necrosis of tissue characteristic of diphtheria.

Loeffler's own experiments were divided into three parts:—

(1) Histological examination of the tissues of patients who had succumbed to diphtheria (tonsils, pharyngeal and laryngeal mucosa, internal organs).

(2) "Pure" cultures on solid substances of two species of bacteria discovered during above examination; namely, micrococci in chains and a species of bacillus.

(3) Inoculation, subcutaneous, muscular, corneal, or tracheal, of products of such cultures, from the fourth to the twenty-fifth generation, upon several species of animals (mice, Guinea pigs, rabbits, pigeons).

The micrococci sufficiently resembled those which have been so often previously described, but were found not only in colonies, but in long chains. These were abundant in cases of diphtheritic ulceration without pseudo-membrane, but coincided also with that, and then were found on its outer surface. On sec-

tions from ulcerated tonsils, colored with aniline, the micrococci were found in a narrow blue border lying on the outer side of a broad zone of uncolored tissue. Associated with them were numerous bacteria and rods. The uncolored zone was marked by blue streaks, where colored bacteria had penetrated.

This uncolored zone represented tissue necrosed under the influence of a poison produced by the layer of bacteria.

In many, but by no means in all, cases the capillaries of the internal organs were filled or even obstructed by chain micrococci, and these were sometimes found in the lymphatics of the lungs; sometimes in the lymphatics of the tonsils, or pharynx, though in many cases these tissues were expressly declared to have been free from them. Still, in the general summary of his results, Loeffler admits that the micrococci entered the organism through the open portals of the local lymphatics.

But these micrococci are morphologically identical with those found with any infectious disease associated with lesions of mucous membrane, such as variola, typhus, or puerperal fever. In these diseases they are unquestionably accidental complications, and must therefore be supposed to be so in diphtheria. They are frequent in scarlatinous diphtheria, whose "pultaceous" exudation differs from that of true diphtheria in containing very little fibrine, consisting chiefly of epithelial cells, leucocytes, and fat globules.

The other principal form of micro-organism observed consisted of bacilli considered by Loeffler to be identical with those described by Klebs, in 1883, at the International Congress. These are motionless rods, partly straight, partly curved, about the length of the tubercle bacillus, but double the breadth, coloring intensely with methyl blue potassa solution, discoloring again with dilute iodine, except at both extremities, which remained blue. These blue poles were thought by Klebs to be spores, but Loeffler denies this.

These rods are present in great abundance in diphtheritic pseudo-membranes; they do not lie on the surface as a mass of heterogeneous accidental bacteria, but underneath this outer layer, and accompanied by a rich abundance of cells. Both cells and bacilli disappear from the deeper broad fibrous layer placed directly upon the enormously dilated blood-vessels.

These bacilli are never found in the internal organs, in the blood-vessels, or in the lymphatics. Thus there is no reason to suppose that they act by penetrating the organism, but they perhaps produce a poison at the seat of their implantation, which first causes necrosis of the tissues in immediate contact with them, then enormous dilatation of paralyzed vessels, through whose injured walls the poison passes into the circulation, causes parenchymatous congestions, fibrinous exudations on free surfaces, and ultimately paralysis of nerve centres and death.

In a certain number of cases of typical diphtheria no such bacilli were found, although other bac-

† Thirty cm. of concentrated alcoholic methyl blue solution to 100 cm. of a watery solution of potassa, 1:10,000. Pseudo-membranes were cut on a freezing microtome, then hardened in alcohol, and stained by a few seconds' contact with the solution, washed in one-half per cent. acetic acid solution, and mounted as usual in balsam.

ria were present. Loeffler suggests that they have died and been eliminated before the death of the patient.

The micrococci were isolated by the usual devices, and cultivated upon meat-water-peptone-gelatin. When taken from internal organs, the latter were previously washed, first in a five per cent. solution of carbolic acid, then in a one per cent. solution of corrosive sublimate. The results of inoculation with the products of the culture were negative upon Guinea pigs. In mice and rabbits death usually occurred after subcutaneous injection; not after inoculation, nor after injection into veins. Injection into the lung was followed in one mouse by death only on the thirty-fourth day. Fibrinous purulent exudations were frequently observed over the spleen, liver, lungs, and over the intestine when injections were made into the peritoneal cavity. The exudations contained many micrococci, and they were also abundant in the visceral capillaries. In some rabbits after injection into the aural vein, a multiple arthritis resembling that of scarlatina was developed; and when the animals were sacrificed, purulent masses, infiltrated with micrococci were found in the joints.

Loeffler concludes: "Since the chained micrococci excited in no animal an artificial disease even resembling diphtheria: since they were only observed in a limited number of cases of human diphtheria, and then associated with bacilli: since they exactly resembled the micrococci of erysipelas and other infectious diseases, we must conclude that they are only accidental complications of diphtheria, but may sometimes excite a disease resembling it."

Cultures were then made with the other microorganisms, the bacilli were isolated and cultivated upon stiffened blood serum. They will not develop on the meat-water-peptone-gelatin, partly at least because this softens at a temperature about 20° C., and a temperature higher than this is essential to the development of this species of bacilli. A temperature of 60° C. kills them. The duration of their life seems to be about three months.

The result of experiments conducted with these new bacilli is summed up by Loeffler as follows: They were found in thirteen cases of diphtheria with fibrinous exudation; they lay in the oldest part of the membrane and penetrated further toward the tissues than the other bacteria; products of the cultures of them, carried to the twenty-fifth generation, when inoculated under the skin of Guinea pigs and small birds, kill the animals, after the production of a whitish or hemorrhagic exudation at the point of infection, and extensive subcutaneous oedema. The inner organs remain intact, as do those of diphtheric patients. Pseudo-membranes are generated by inoculation of the trachea of rabbits, chickens, and pigeons, or of the vagina of Guinea pigs. There are then also evidences of several vascular lesions, manifested by hemorrhagic oedema, by hemorrhages into lymphatic glands, and effusions into the pleural cavity. The bacilli have thus the same effects on the animal organism as the diphtheric virus.

Dr. G. B. HORN said that the subject of diphtheria came more under the notice of the general practitioner than that of the specialist. Yet, recently

he had seen a case in a boy of seven years who, without constitutional symptoms, had presented, on the tonsils, two distinctly diphtheritic patches as large as a ten-cent piece. The speaker applied a strong solution of nitrate of silver, 5iss. - ʒi., and afterward learned that the boy died several days later with diphtheritic croup, the patches in the fauces never having extended. The case was of interest on account of this independent development of membrane upon the two parts.

Dr. E. S. DANA remarked that, as is well-known, diphtheria causes paralysis more often than any other infectious disease. This paralysis may be accompanied with permanent muscular atrophy, as in the following case which he had under treatment: The patient, a young man of twenty-two years, with the appearance of good health, presented himself, one year ago, stating that he was a bar-keeper and that he could stand without inconvenience seventeen hours out of the twenty-four, but that if he sat down he could not get up without using his hands to assist him in rising from his seat, and that, if he were thrown upon the floor, he could not get up at all without assistance. Upon examination, wasting of the quadriceps extensor and of the leg muscles upon both sides was found. There was, in these muscles, a diminution of electrical excitability, slight to galvanism, but to faradism very marked. There was no diminution of the sensibility. There was no bladder or rectal trouble. He was married and had children. Five years previously he had had diphtheria, following which he had pains in the arms and legs with a loss of power which affected principally the lower extremities. At the end of two or three weeks he got up, and at the end of three or four weeks commenced to walk. He never fully regained his power, and it was after this time that the atrophy occurred. He had had no other disease. It seemed probable that, connected with the diphtheria, he had had a myelitis of the anterior horns like that which occurs in infantile paralysis. It should be borne in mind that during epidemics of diphtheria cases of diphtheritic paralysis occur where there have been no local signs of the disease.

Dr. W. O. MOORE said that in eye practice two classes of cases of diphtheria were encountered, the first and more rare being an acute affection of the conjunctiva, characterized by the formation of a pseudo-membrane on its surface, and also an infiltration of the lid substance. This diphtheria of the conjunctiva is very rare in this country, although quite common in Germany, especially in Berlin. Out of 36,302 cases of conjunctivitis, treated during thirteen years at the New York Eye and Ear Infirmary, only sixty-nine were diagnosed as of diphtheritic origin, and he had no doubt some of those were improperly so called. He had himself only seen fifteen cases that were positively of this form. When seen they present an entirely different appearance from the ordinary membranous forms of purulent conjunctivitis. The lids are hard and branny, more or less pale, hard to evert, with very little secretion. Chemosis and moderate injection of the conjunctiva exists, and the palpebral conjunctiva is covered by a grayish-white membrane that extends into the tissue beneath the mucosa.

The prognosis is bad unless seen early. The treatment differs from the more ordinary purulent conjunctivitis in that we use no astringents, simply keeping the parts clean with bichloride solutions 1-400, or a saturated solution of boracic acid. Later in the disease, after the disappearance of the pseudo-membrane, we treat exactly as in other cases of conjunctivitis. Most reliance is to be put in general tonic treatment.

The more common affections of the eye resulting from diphtheria are the pareses that occur. Paresis of accommodation may occur shortly after diphtheria or, in rare cases, at the same time that the paresis of the throat occurs; it usually happens in both eyes, due to disturbance in the short root of the ciliary ganglia.

In other cases the motor-oculi is affected, and more rarely the abducens. These usually yield to treatment in a short time, tonics and applications of electricity being of great service.

The chairman in the New York Foundling Asylum had had an outbreak of puerperal fever in the maternity at a time when there was diphtheria in the children's wards. It was required that the internes should change their clothing and bathe carefully before going from the diphtheritic patients to the puerperal patients. The first case of puerperal infection had dated from a violation of this rule. He considered that poison had been carried in this way, although three hours had intervened between the visits to the two wards.

DR. FRANK B. CARPENTER presented a specimen accompanied by the following history: The patient, a child of about two years of age, had been in his usual good health until Tuesday, the ninth instant, when slight coryza and cough appeared. These symptoms increased, until on Wednesday the nasal discharge had become mucopurulent, the cough had become stridulous, and dyspnea was noticed. From that time the respirations grew gradually more obstructed, being only slightly relieved by the emetics and other domestic remedies that were used. When he first saw the case on Friday, the fourth day of the disease, the dyspnea was severe, the character of the respirations clearly showing laryngeal stenosis. The submaxillary and cervical glands were but little enlarged. The tonsils were somewhat swollen and the whole throat congested, but did not have the dark-red congestion occurring in patches usually found in diphtheria. A careful examination for the fauces and nares failed to reveal any diphtheritic membrane in those parts, nor did any develop there during the course of the disease.

In short, this case presented the clinical features of membranous croup, as it is usually described, rather than those of diphtheria.

In view of the prevalence of the latter disease the unsatisfactory condition of the place and the belief which he entertains that there exists between croup and diphtheria a very intimate relation if they are not in fact identical, the case was treated as diphtheria taking the precautions usually deemed necessary to prevent the spread of the disease. Subsequent events seem to have justified this course. On the following day a child in the same family, seven months of age, began to show symptoms of diphtheria, which developed rapidly. The submaxillary

and cervical glands became swollen, characteristic membrane appeared on the tonsils, together with other symptoms which showed conclusively that the case was one of diphtheria.

The child first attacked grew gradually worse, and tracheotomy was advised, but not allowed by the mother. Death occurred on Sunday, the sixth day of the disease, from apnea.

In a disease like this which has no typical course, which is so insidious in its advent, so uncertain in its development, and so fatal in its results, no delay is admissible and no detail of treatment that offers any hope of success can safely be ignored.

The nasal cavity should be thoroughly cleansed with a mild antiseptic solution, and all mucus cleared from the throat, so that a clear view of both can be obtained. If any patches of diphtheritic membrane can be seen, they should be brushed with some mild antiseptic preparation; care being taken not to irritate the already inflamed membrane of the throat. The oil of eucalyptus answers the indication here, being nonirritating and remaining in contact with the mucous membrane. As this oil is also a good deodorizer, it is especially useful in cases where the discharges are fetid. Hot fermentations or poultices should be applied to the neck and covered with oil silk to retain the heat and moisture and prevent chilling the patient.

The medicated steam spray should be freely used. As to constitutional treatment, *pure air* at an equal temperature of about 75° F., a plain, nutritious diet, and tonics such as the tinct. ferri chloridi and hydrarg. bichlor., which also produce a local effect in the way they are now prescribed, appear to meet the indications. Stimulants should be commenced as soon as the slightest evidence of cardiac weakness appears.

I have given these points in treatment not as anything new but only to emphasize the importance of early and thorough treatment, feeling confident that we can sometimes prevent the development of constitutional symptoms, and often forestall the disease and mitigate its severity.

DR. H. M. GILD, of Vermont, considered the infection of diphtheria to be by direct contagion, frequently through the sputa, the hand touching the mouth, and, later, the door-handle or other object. He relied upon frequent syringing with salt and water or lime-water, using a tube which was passed into the nostril, the operator standing behind. If he could have but three remedies to combat this disease, he would choose a syringe, water, and whiskey. In cases where the temperature had been 103° and 103½° he had, by injection in the nasal passages and throat, reduced it 2½° to 3° in one hour.

DR. THOS. E. SUTTERTHWAITE, commenting on the experiments cited by the speaker of the evening, said that they had utterly failed, by injecting the diphtheritic deposit into irritated air-passages and by inoculation beneath the skin, to produce results which in any way differed from those which are obtained from the injection of any putrid material. As a rule abscesses were produced in animals with a residual cheesy mass. The animals emaciated but did not always die. He then exhibited a series of microscopic specimens taken from a diphtheritic

larynx and showing the membrane *in situ*. He also showed sections taken from a larynx in which a diagnosis of membranous croup had been made by a well-known authority on children's diseases. He could not discern any essential difference in minute structure between the two membranes, and in this view he believed he was sustained by the general opinion of pathologists in New York. He also called attention to the old-time definition that a croupous deposit is one which reposes upon the surface, while the diphtheritic deposit is one which also infiltrates the mucous tissue of the part so as to be separated with difficulty. As a point of fact, he held that every diphtheritic membrane would at times be found tightly attached at some places and loosely at others. In Dr. Carpenter's specimen the membrane was tightly attached upon the epiglottis and larynx, but below it could be easily removed. The speaker considered that this loosening had been largely due to the action of the muciparous glands, as had been pointed out by Dr. Jacobi, the glands being absent where it still adhered. Specimens were exhibited showing how this separation was accomplished. He did not consider that the mucous membrane was materially altered where the exudation occurred. He had seen the ciliated epithelium immediately underlying the membranous deposit.

(To be continued.)

## Recent Literature.

*Anatomy, Physiology, and Hygiene: A Manual for the use of Colleges, Schools, and General Readers.* By JEROME WALKER, M.D., etc. etc. With original and carefully selected illustrations. New York: A. Lovell & Co. 1881.

The author of this book states in the preface that its pages are based upon his lectures in the public schools of Brooklyn, during the last eight years, holding as he does the appointment of lecturer at the Central School upon the three subjects discussed. The different chapters, he also tells us, have been carefully reviewed in manuscript and proof by well-known and capable specialists in the various branches of medicine of which they treat.

Such a preparation should make a reliable and useful book, and we think it may be regarded as such. The term "manual" has been respected. Although there are 415 octavo pages, divided into twenty chapters, some appendix notes, and an index, convenience of size as a textbook has been secured. A certain number of the cuts are original, but the majority are taken from Sappey's Descriptive Anatomy, and most of them are decidedly good. There are a good many footnotes of elucidation, and at the end of each chapter a series of questions to aid the teacher.

The author has, as a rule, cleverly achieved conciseness without dogmatism, and, whilst not neglecting what is new in physiology and hygiene, has kept pretty clear of still disputed theories. We can recommend the book for the purposes for which it is designed.

## Medical and Surgical Journal.

THURSDAY, JANUARY 15, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by CUPPLES, UPHAM & Co., Boston. Price, 15 cents a number; \$5.00 a year, including postage.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUPPLES, UPHAM AND COMPANY,

283 WASHINGTON STREET, BOSTON, MASS.

## THE OFFICIAL REGISTER OF PHYSICIANS IN ILLINOIS.

We have recently received the third edition of the Official Register of Physicians and Midwives in Illinois. The State of Illinois is naturally looked upon as the leading State of the Union in the regulation by law of the practice of medicine, and the official reports of the Board of Health, to which is entrusted the execution of the laws, must be of interest to all who have at heart the good of the profession and the protection of the community from those who would make man's necessity the prey of their selfishness.

This register contains the names of 5,585 physicians to whom certificates have been issued. Of these certificated practitioners there are 4,780 who hold certificates based upon satisfactory proof of having received diplomas or licenses from legally chartered medical institutions in good standing; 102 have received certificates after passing satisfactory examination before the board; 703 are non-graduates who have voluntarily taken out certificates based on ten years of practice prior to the passage of the regulating act, although not required so to do by law. To this number, to make up the total number engaged in the practice of medicine in the State, must be added 300 practitioners who are exempt from the provisions of the law, having practised in the State ten years prior to July 1, 1877, and who are simply registered in the office of the county clerk of their respective counties. The comparative statistics of the three editions of the register seem to show an improvement in the character of the practitioners, as the following table will indicate:—

	1880, June 11.	1881, Dec. 29.	1884, Dec. 1.
Graduates and Licentates of Medical Institutions . . . . .	4,282	4,488	4,780
Licentates upon examination of the State Board of Health . . . . .	191	181	102
Exempt non-graduates, certified . . . . .	518	591	703
Exempts non-certificated . . . . .	538	420	300
Total number engaged in practice . . . . .	5,529	5,587	5,885

The change in the status of practitioners since the Medical-Practice Act went into operation is

best shown by percentage. In 1877, at the passage of the Act, the number of non-graduates was 52 in the hundred. On December 1, 1884, the non-graduates were reduced to 15 in one hundred. One naturally inquires what class of graduates have made up this large percentage. A comparison of the number of graduates from the institutions which have furnished the greatest number of practitioners to the State, as given in the register of 1879, and in that of 1884, gives, on the whole, cause for congratulation. The following table will illustrate:—

GRADUATES PRACTISING IN ILLINOIS.

	In 1884.	In 1879.
Rush Medical College . . . . .	822	719
Chicago Medical College . . . . .	280	268
Hahnemann Medical College, Illinois . . . . .	274	221
Eclectic Medical Institute, Ohio . . . . .	240	248
College of Physicians and Surgeons, Iowa . . . . .	228	210
St. Louis Medical College . . . . .	196	213
Missouri Medical College . . . . .	190	185
Jefferson Medical College, Pennsylvania . . . . .	179	169
Bennett Coll. of Eclectic Med. and Surgery, Ill. . . . .	178	141
Medical College of Ohio . . . . .	176	158
University of Michigan . . . . .	137	107
Bellevue Hospital Medical College, N. Y. . . . .	108	89
American Medical College, Missouri . . . . .	89	77
Homeopathic Medical College, Illinois . . . . .	87	43
Physio. Medical Institute of Ohio . . . . .	25	26
Physio. Medical College of Ohio . . . . .	8	7

Even with the slight decrease in the total number of practitioners, the income of a physician in Illinois is not of necessity a large one, as a comparison with the population, as shown by the census returns of 1880, shows one physician to every 523 inhabitants.

That the licensing power maintains a careful supervision is evident from the list of thirty-one licenses that have been revoked, some of them for fraudulently using diplomas to which they had no rightful claim, if our understanding of the word *alleged* is correct.

That this work of the Board of Health is not permitted to go on without occasional remonstrances is shown by a recent newspaper item to the effect that, in the Superior Court, arguments were heard in the case of the State Board of Health against Dr. L., charged with practising medicine without a license, the board having revoked its certificate. The defence held that after the board once passed upon the eligibility of a practitioner to do business, they had no further power over him, and could not revoke their license. The judge held that they could, and imposed a fine of \$50. An appeal was taken, and the case will go to the Supreme Court.

#### NEW REMEDIES.—EUPHORBIA PILULIFERA.

A good remedy for asthma will always find a welcome. Quebracho seems to have had its day, though still deservedly held in estimation. The new candidate for favor, which promises speedy and sure relief for the dyspnea of spasmodic asthma,

of chronic bronchitis, and emphysema; which will better than stramonium and the iodides right the hobbling machinery of hæmatosis, is *euphorbia pilulifera*. Extraordinary testimony, chiefly from foreign sources, comes to us respecting the efficacy of this herb as a respiratory stimulant. Certain Australian physicians, Drs. Matheson and Shephard, also Carr-Boyd, have reported wonderful success with this remedy in asthma and all affections of the air-passages attended with difficult breathing. We are told that this plant is not merely indigenous in Queensland, but is abundant also in the tropical regions of Asia and Africa, and in South America. One case is reported in which the patient had been a victim of asthma complicating bronchitis for eight or nine years, to such an extent that he found himself unable for many nights in succession to sleep, except in a sitting posture. The administration of *euphorbia pilulifera* was followed by immediate and permanent relief.

This case would seem from the communications of these physicians to be typical of multitudes of cases within their experience where individuals, long sufferers, have derived lasting relief from the free use of a simple decoction of the pill-bearing spurge.

This decoction, according to the directions of the *Pacific Medical and Surgical Journal*, is made by simply steeping one ounce of the fresh weed—or one half-ounce of the dried plant—in two quarts of water, and reducing it by simmering to one quart. Of this decoction the dose is a wineglassful. This plant, according to Dr. Boyd, is as common in Australia as the pig-weed is in this country, and is largely resorted to by the natives in pulmonary complaints. Other testimony of a similar kind comes from Jamaica; notably that of Dr. Bancroft. During the past year Dr. Tison, a practitioner, of Paris, has published several interesting papers on the *euphorbia*, in which he details his own favorable experience of the antiasthmatic properties of this spurge, and quite lately has appeared the instructive *thèse* of Dr. Marsset, late of the Hôpital Clermont-Ferrand, in which he reports twelve cases, nine of which came under his own observation, where the most signal benefit was obtained in organic or spasmodic dyspnea by the free use, after the evening meal, of the infusion or aqueous extract of *euphorbia pilulifera*. He strongly recommends the dried plant, infused in the manner above described,—dose three or four wineglassful,—or the aqueous extract in the dose of one or two grains a day.

Some of these patients who were so remarkably relieved of all their breathing troubles—and one gentleman (Case IV.) who had been unable for several months to work, or even to lie down, was cured in a few days' time by *euphorbia*—were patients in the care of Dr. Dujardin Beaumetz, of the Hôpital Cochin, and their cases seem to have been reported with fidelity and much pains.

Dr. Marsset relates with great minuteness the numerous physiological experiments which, while a student in the laboratory of the Hôpital Cochin, he performed on animals to ascertain the toxic effects and mode of action of the euphorbia. He used, for the purpose of experimentation, the aqueous extract of the dried herb, well diluted in water, and either poured it down the throats of his animals (frogs, Guinea pigs, hares), or injected it under the skin of the back. He found the medicament inert in small, and quite toxic in large, doses, the symptoms of fatal intoxication being marked distress and agitation, acceleration, then slowing, of the heart's action, and especially of the respiratory movements; finally collapse. The necropsy, revealing some congestion of the lungs and bronchi, a well-pro-nounced injection of the gastric mucous membrane where the poison was administered by the mouth, and distention of the gall-bladder and bile-ducts. The symptoms and post-mortem appearances, he affirms, resemble those where death takes place from section of the pneumogastries, and the drug is believed to act by modifying the vagus centre in the medulla oblongata. The toxic action is somewhat irritant to the mucous membranes; it seems to be chiefly eliminated by the liver.

As for the active principle of the euphorbia, it would appear to be a gum resin, soluble in water or dilute spirit; no alkaloid has yet been discovered.

It has not yet been determined what remedial principle this particular euphorbia (the pill-bearing spurge) has which the other euphorbias have not, or whether the same antiasthmatic properties may not be possessed by other members of this large botanical family: a family which comprehends more than twenty-five hundred different species, all characterized by their acrid, milky juice (in which the toxic principle resides) and their singularly anomalous inflorescence.

If this new remedy should really prove to be what the foreign testimonials above referred to seem to justify us in expecting, it will be a most valuable addition to our materia medica.

#### BRAIN-SURGERY AND VIVISECTION.

WE regret to learn from the London papers that the patient operated upon by Mr. Godlee for brain-tumor, as reported upon in our last issue, has finally died, after a favorable convalescence of four weeks, "from one of those complications by which any surgical operation may be attended."

The case will none the less retain its historical importance as being one of the first to inaugurate a new departure in surgical treatment, and as signally illustrating the practical service that physiology is able to render to therapeutics.

In our late editorial we said we were not aware that a cerebral-tumor had previously been removed.

The correspondence to which this late event has given rise has, however, developed the fact that Mr. Macewen, of Glasgow, has, within the past five or six years, twice successfully removed foreign growths, the position of which had been diagnosed by means of the discoveries in cerebral localization to which we last week referred.

Mr. James Whitson, assistant surgeon to the Glasgow Royal Infirmary, in a letter to the London *Times* of December 26th, gives a brief sketch of these cases of Macewen's, and, besides them, of a number of others, of localized abscess, effusion of blood, etc., which the same surgeon had diagnosed and successfully treated by operation.

Even before Macewen, however, Broca (in 1871) and Lucas-Champonnière (in 1874) had successfully applied the principles of cranio-cerebral topography in operations upon cases belonging to this latter group (in the case of Broca pus was sought and found over the speech-centre), so that the interest of novelty really attaches to the removal of tumor alone. It may be of interest to recall that Dr. E. C. Seguin, in a paper published in the *Archives of Medicine* (volume viii., December, 1882), gives a thorough and careful statement of the lessons contributed to surgery up to that date by the physiological and clinical discoveries in localization, citing the two last-mentioned authors and others; and Dr. F. C. Fuller, in 1884 (*Archives of Medicine*, volume xi, page 262), reports four new cases of his own, besides analyzing numerous cases of other observers.

The London *Spectator* of December 27th, with a characteristically narrow bigotry, tries to belittle the value of the contributions made to therapeutics through Dr. Ferrier's experiments, by pointing out that Mr. Macewen had already learned all that was required for the localization and removal of tumors, by post-mortem examinations alone. It is enough to excite one's impatience and indignation to see an intelligent writer stoop to use any argument, if only effective, without asking himself whether or not he is in a position to understand its bearing. The letter from Macewen's assistant contains no such claim, and it is one that is utterly unjustifiable. Whether post-mortems alone would ever have given us our present knowledge of cerebral localization is doubtful; that they in fact did not is certain. It is an easy but an ungenerous task for the landsman, standing safely on the shore of a newly discovered country, to trippingly criticize the action of the mariners who brought him thither.

The antivivisectionists, as a class, are ready to allow torture and indignity to man or beast to protect the pockets of the nation; and they foster a system of terrible attack upon the life and liberty of individuals—whom they call criminals—solely on grounds of practical expediency. Yet they are either too illogical to allow the physiologist the right to the same argument, or else so unjust that they deny him the privilege of bringing the question

of expediency before a jury of his peers. And this in face of the almost unanimous judgment of the medical profession, who stand between the *suffering portion* of the community and the physiologists, and declare that a decent regard for humanity demands that the community shall not be deprived of the splendid results which these men are achieving, until the cost shall be shown to be greater than now.

So far from its being necessary that physiological investigations should commend themselves at every step to non-experts, it would be, in most cases, a warrant of the shallowness of the research that such a ratification was possible, when one thinks of the infinite intricacy of the labyrinth through which physiologists and physicians are trying, by the guidance, now of experience, now of trained instinct, to force their way. Physiologists may well listen to appeals to their humanity, from whatever source, but they should not listen to dilettante criticisms of their investigation.

... "For he made me mad  
To see him shine so brisk and smell so sweet,  
And talk so like a waiting-gentlewoman  
Of guns and drums and wounds (God save the mark!);  
And telling me the sovereign'st thing on earth  
Was parmaceti for an inward bruise;  
And that it was a pty, so it was,  
That villainous saltpetre should be digged  
Out of the bowels of the harmless earth,  
Which many a good tall fellow had destroyed  
So cowardly; and but for these vile guns  
He would himself have been a soldier."

## Correspondence.

### LETTER FROM SAN FRANCISCO.

215 Geary St., San Francisco, December 18, 1884.

MR. EDITOR, — In your issue of November 27th, under the head of "Proceedings of the Boston Society for Medical Improvement," I note the discussion had upon the present unusual prevalence of Scabies, and confess much surprise at the remarks made by Dr. J. C. White upon that occasion. He says: "Before the war of the Rebellion, it was so little seen as not to be recognized by practitioners, and during the war it was regarded, in the armies, as an unusual form of skin affection, and extended from them over the whole country." Possibly this statement may be true as regards the recognition of the affection by the profession, but it was sufficiently well-known among the people under the title of "Itch;" and the treatment necessary for its cure was well-known, namely, the thorough immersion, before a warm fire, of the entire body, with sulphur ointment, for three consecutive nights, followed by thorough bathing and boiling of the clothing in hot water. The first fourteen years of my life were spent in Bolton, Worcester County, Massachusetts; for five years of this time, Professor R. T. Edes, of Harvard Medical School, and myself attended school together. During that period it was not an uncommon thing for some of the pupils to have a case of "itch," not bad, and at once attended to at home, but at the same time genuine,

and which could be demonstrated by the plucking out of the insect from the *sillon* which he had made, and placing it upon a piece of glass, where its movements could be seen with the naked eye. Among my early boyhood recollections is that of carrying a piece of roll-sulphur in my pocket as a prophylactic against "itch."

As sustaining, however, the statement of Dr. White with reference to the non-recognition of the affection by the profession generally, I send you the following:—

In the early fall of 1863, the writer, then in charge of the United States General Hospital at Madison, Indiana, was ordered to report for duty to General Burnside, commanding the department and army of the Ohio, at Knoxville, Tennessee. Soon after reporting for duty he was assigned as medical director of the Ninth Army Corps. Three or four days after assignment the assistant surgeon Second Maryland Volunteer Infantry reported the breaking out of a peculiar skin disease in his regiment which had spread very rapidly through the brigade to which his regiment was attached. He stated that it had resisted all treatment, and that nobody had been able to say what it was; furthermore, the men were rapidly becoming unfit for duty, and that, unless something was done speedily to check it, the entire brigade would be disabled. Riding down to the surgeon's quarters, several of the worst cases were brought in for inspection, and from their condition no one could be surprised that the affection should be regarded as "unusual." Being stripped naked these cases presented nothing but a continuous mass of diseased skin, from the crown of the head to the soles of the feet, and every conceivable type of skin disease was present—squamous, vesicular, bulla, pustular, etc. etc.

Sending out again for a case that had only just begun to show traces of the disease, the use of my penknife speedily dislodged a specimen of the *Acarus Scabiei* which was displayed on my thumbnail before the astonished doctor's eyes. Of course the diagnosis was plain, but the next important question was: "What shall we do with it?"

By this time the little army under Burnside in East Tennessee was practically cut off from supplies; the only route open was by Cumberland Gap, and everything had to come by this long route by army wagons. Even this route was to be speedily closed by the great disaster to our army under General Rosecrans at Chickamauga. A council of doctors was had to settle our problem or conundrum. All were agreed that the affected portion of the command should be quarantined; but when the question was mooted as to treatment nearly all were equally unanimous in recommending "sulphur ointment." There was, however, no sulphur, and none to be had; no lard, and none to be had. One thing after another was proposed, only to be abandoned as impracticable. The question was finally left in the hands of the writer for solution.

The solution was as follows: All the affected portion of the command, including the officers, was removed to the banks of a small stream, about a mile distant, and a guard placed around them.

A "detail" was sent through the neighboring country with wagons to bring in thirty or forty of

the large iron kettles, used by the people of that section for washing purposes. At the same time, the "detail" was instructed to obtain from the citizens eight hundred to a thousand pounds of tallow, of which there is always to be found a supply.

When these had been brought in and the kettles placed in position a quantity of blank cannon cartridges was obtained from the ordnance department. Our medical stores were drawn upon for all the sweet and castor oil that could be spared, and the work of preparing *gunpowder ointment* was begun. Many camp-kettles full were prepared, and then the men were ordered to strip and be "anointed." They entered heartily into the thing, and a more comical sight than was presented by these twelve to fifteen hundred men, stark naked, and black as the ointment could make them, dancing around and cutting up all sorts of pranks, one could scarce ask to witness. This process was kept up twice daily for three days, at the end of which time, the men were carefully washed and the clothes thoroughly boiled.

This ended the whole thing, and a calamity that was assuming very serious proportions was averted. The writer afterward ascertained that the "itch" was almost indigenous to the soil in the valleys of East Tennessee, and that no one thought much about it. That the affection was thought to present unusual appearances must be explained by the failure to recognize it till the irritation, scratching, and filth, had developed secondary skin affections, completely concealing the real disease.

True Scabiei, as we all know, can only be caused by the *Acarus Scabiei*, and the result of this little creature's work must always be the same.

There are probably many of the participants of the above-described experience still living as witnesses of the truth of my statements, to whom I extend cordial greeting. Very truly yours,

A. M. WILDER, M.D.,

*Late Surg. and Brevet Lt.-Col., U. S. Volunteers.*

### DR. DARLING'S POEM.

PHILADELPHIA, January 3, 1885.

MR. EDITOR,—In your issue of the 1st inst., in the notice of Professor Darling, the writer states that he was the author of the celebrated poem known as "Lines in a Skeleton," or "To a Skeleton," beginning "Behold this ruin! 'T was a skull." It would be interesting to know on what authority the statement is made. It appeared, so the notice usually runs, in the London *Morning Chronicle*, and was found near a skeleton in the Museum of the Royal College of Surgeons, London,—not in the cavity of a young girl's skull. If, as stated in the *Cyclopædia of British and American Literature*, it was published in 1807, Dr. Darling could not have been the author, and the secret of this beautiful poem remains unrevealed.

Yours very truly,

WILLIAM OSLER.

The poem of which Professor Osler quotes the first line in the above communication, and that referred to in our New York notes, are probably

not identical. Our New York correspondent informs us that the poem attributed to Dr. Darling was privately printed and a proof-slip was seen in his possession by an old friend and pupil, who received from him the impression that it was for the name of the author of this poem that the sum mentioned had been offered. — [Ed.]

## Miscellany.

### OBITUARY.

WILLIAM H. THORNDIKE, M.D.

DR. WILLIAM H. THORNDIKE, whose recent death has left a large void in the medical profession of Boston, exemplified so well for thirty-five years the life of a good physician that it is difficult to do his character justice in an obituary notice.

Modest in bearing, Saxon in speech, reticent of many words, his calm judgment, clear perception, and entire honesty, commended him to the confidence alike of friends and patients.

He was the type of unselfish devotion to his calling. He pursued medicine as a profession, and not as a trade. Too careless, perhaps, of pecuniary returns, he lived in his cases, gave himself wholly to his sick, and was death-struck while attending a professional call.

Beginning to practice in a somewhat isolated community at East Boston, he early learned to rely wholly on himself, and never hesitated to undertake anything he was called on to do. Thus was developed a peculiar roundness and completeness of character usually found only in the country doctor. To this he added the wide experience and versatility generated in great cities, and both were concentrated and widened by seventeen years' service as surgeon of a great hospital. All departments of medicine and surgery, many of which are now consigned to specialists, he practised without hesitation and with success.

He belonged to the older school of surgeons. Natural taste, acquired dexterity, long practice, had made him a deft, intrepid, and successful operator. He loved his art. With him to see clear was to do. Diagnosis was followed by action. Expectation in surgery he well recognized as of less value than in medicine. For twenty years, both in private practice and in the hospital, he did an enormous number of operations, surgical, gynecological, obstetrical, ophthalmic. An enumeration would be tedious, and we will allude only to the unusual ones. He tied the internal iliac artery, behind the peritonæum, for secondary hæmorrhage from a perforating wound, and the patient lived to attend the funeral of his surgeon. He tied the external iliac vein for primary hæmorrhage from a stab with success. He tied the gluteal artery at its emergence from the sciatic notch for a traumatic aneurism in the nates. In this he boldly imitated Bell, who so graphically describes the rush of blood and clots and the difficulty of seizing the vessel. He removed a cobblestone, five inches by three, and weighing two pounds,

from the peritoneal cavity with success. In this remarkable case the patient had inserted the stone into his rectum, thence it had ulcerated through the rectum and colon into the peritonæum. Dr. Thorn-dike passed his hand into the rectum, but the stone escaped beyond his reach. He then opened the peritoneal cavity by an incision five inches long, parallel to the rectus muscle, and removed the stone. The patient recovered.

He opened the gall-bladder, and removed calculi by incision.

Among the surgical feats he prized the most were two operations for evacuating pus from a retro-peritoneal abscess near the cæcum. The symptoms in his first case were constitutional more than local, but very intense. He made the incision to tie the iliac artery, pushed back the peritonæum, found a mass of induration in the iliac fossa, plunged in a trocar,

and was rewarded by evacuating pus, and the perfect recovery of his patient. Most of these operations were done before the days of antiseptic surgery. The removal of Meckel's ganglion for neuralgia, amputation at the hip-joint, many lithotomies, Cock's operation for perineal section,—which he valued highly,—many large tumors, might be added to the list. He also had practised every operation of modern gynaecology except Battey's operation.

A large, continuous, and exacting private practice gradually wore him out; but his constitution was also sapped by a poisoned wound received three years ago. He sank rapidly under a double pneumonia, and died in forty-three hours from the primary chill, apparently unconscious of suffering.

DAVID W. CHEEVER, M.D.

Deaths reported 2544, under five years of age 1066; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrheal diseases) 513, lung diseases 189, consumption 377, diphtheria and croup 232, scarlet fever 57, typhoid fever 19, diarrheal diseases 12, measles 7, malarial fever 54, whooping-cough 18, erysipelas 18, cerebrosplenic meningitis 14, purpural fever 19. From *diphtheria* 10, *scarlet fever* 10, New York one, Philadelphia four, Brooklyn two, Chicago and Chelsea three each, Baltimore and St. Louis two each, Boston, District of Columbia, Charleston, and Hoboken one each. From *measles*, New York 29, Cincinnati six, Chicago four, Philadelphia and St. Louis three each, Brooklyn, Boston, and Gloucester one each. From *malarial fever*, Brook-

lyn ten, New York seven, New Orleans six, Baltimore four, St. Louis three, Philadelphia, Nashville, Charleston, and Springfield one each. From *whooping-cough*, New York six, Brooklyn three, Chicago and New Orleans two each, Philadelphia, Boston, Baltimore, District of Columbia, and Lynn one each. From *erysipelas*, New York six, Philadelphia, Brooklyn, and Boston two each, Chicago, St. Louis, District of Columbia, New Haven, Lynn, and New Bedford one each. From *cerebrosplenic meningitis*, New York three, Philadelphia, St. Louis, and Fall River two each, Chicago, Boston, Cincinnati, New Orleans, and New Haven one each. From *purpural fever*, Brooklyn four, Philadelphia and Baltimore two each, Chicago and Boston one each.

In 94 cities and towns of Massachusetts, with an estimated population of 1,964,970 (estimated population of the State 1,955,104), the total death-rate for the week was 17.43, against 18.15 and 18.00 for the previous two weeks.

In the twenty-eight greater towns of England and Wales, with an estimated population of 8,762,354, for the week ending December 13th, the death-rate was 22.26. Deaths reported 3798; infants under one year of age 804; neuter diseases of the respiratory organs (London) 457, measles 80, whooping-cough 75, fever 60, small-pox (London) 45, diphtheria 37, diarrhoea 35.

The death-rates ranged from 15.8 in Huddersfield to 34.1 in Preston; Birmingham 22.0; Blackburn 31.2; Bradford 20.9; Hull 29.7; Leeds 22.0; Leicester 22.4; Liverpool 25.8; London

21.3; Manchester 26.7; Norwich 23.7; Nottingham 20.8; Sheffield 21.4; Sunderland 22.0. In Edinburgh 22.4; Glasgow 32.7; Dublin 28.7.

For the week ending December 13th, in the Swiss towns, there were 31 deaths from lung diseases, consumption 28, diphtheria and croup nine, measles seven, diarrhoea six, puerperal fever three, scarlet fever two, small-pox one, typhoid fever one. The death-rates were: at Geneva 20.4; Zurich 11.8; Basle 20.9; Berne 27.8.

The meteorological record for the week ending December 27th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Deaths reported 2495; under five years of age 891; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrheal diseases) 465, lung diseases 466, consumption 342, diphtheria and croup 208, diarrheal diseases 67, scarlet fever 51, typhoid fever 45, measles 32, malarial fever 18, whooping-cough 17, cerebrospinal meningitis 14, erysipelas eight, puerperal fever five. From *typhoid fever*, Philadelphia 17, New York and Boston five each, Baltimore and District of Columbia four each, Cincinnati two, New Orleans, New Haven, Charleston, Lowell, Worcester, Wrentham, and Mansfield one each. From *measles*, New York 22, Philadelphia three, Brooklyn, Boston, and Cincinnati two each, Baltimore one. From *whooping-cough*, New York six, Philadelphia three, Brooklyn, Baltimore, New Orleans, Fall River, Lawrence, Somerville, Dalton, and Randolph one each. From *cerebrospinal meningitis*, New York five, Philadelphia four, Nashville, Lowell, Worcester, Concord, and Millbury one each. From *erysipelas*, Philadelphia and New Haven two each, New York, Brooklyn, Baltimore, and New Orleans one each. From *puerperal fever*, New York two, Philadelphia and Brooklyn one each.

Cases reported in Boston: scarlet fever 41, measles 41, diphtheria 24, and typhoid fever 15.

In 58 cities and towns of Massachusetts, with an estimated

population of 1,246,624 (estimated population of the State 1,955,104), the total death-rate for the week was 19.80 against 17.43 and 18.15 for the preceding two weeks.

In the twenty-eight greater towns of England and Wales, with an estimated population of 8,762,554, for the week ending December 30th, the death-rate was 21.6. Deaths reported 5778; infants under one year of age 839; acute diseases of the respiratory organs (London) 416, measles 101, whooping-cough 91, scarlet fever 62, diphtheria 23, fever 44, diarrhoea 25, small-pox (London 33, Derby two, Cardiff one) 36.

The death-rates ranged from 18.5 in Brighton to 34.1 in Preston; Birmingham 19.4; Blackburn 20.9; Bradford 21.3; Hull 19.3; Leeds 20.7; Leicester 25.5; Liverpool 22.8; London 20.7; Manchester 25.1; Nottingham 21.9; Sheffield 20.7. In Edinburgh 19.7; Glasgow 22.5; Dublin 34.0.

For the week ending December 20th, in the Swiss towns, there were 39 deaths from lung diseases, consumption 27, diphtheria and croup five, measles four, whooping-cough four. The death-rates were: at Geneva 24.5; Zurich 22.8; Basle 15.5; Berne 23.3.

The meteorological record for the week ending January 3d, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY, DURING THE WEEK ENDING JANUARY 10, 1885.

ROSS, J. W., surgeon. Detached from the "Monongahela," for treatment at Naval Hospital, New York.

WELLS, HOWARD, past assistant surgeon. Detached from Naval Hospital, Philadelphia, Pa., to the "Monongahela."

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JANUARY 3, 1884, TO JANUARY 9, 1885.

SHANNON, WM. C., captain and assistant surgeon. Relieved from duty at Ft. Bridger, Wyo., and assigned as attending surgeon at headquarters, Department of Platte, S. O. 2, Department of Platte, January 5, 1885.

ROBINSON, S. G., captain and assistant surgeon. Assigned to temporary duty at Portland, Oregon, from December 17, 1884, S. O. 296, Department of Colorado, December 22, 1884.

APPEL, A. H., captain and assistant surgeon. Granted leave of absence for one month, to take effect on or about January 7, 1885 (Madison Barracks, N. Y.). S. O. 2, Department of East, December 31, 1884.

WATTS, S. G., first lieutenant and assistant surgeon. Relieved from duty at Vancouver Barracks, W. T., and ordered to return to his proper station, Ft. Conr d'Alene, Idaho. S. O. 294, Department of Colorado, December 19, 1884.

#### SOCIETY NOTICE.

SENIOR DISTRICT MEDICAL SOCIETY. *Obstetric and Gynecological Section.* There will be a meeting of this Section at 19 Boylston Place, on Wednesday, January 21, 1885, at 7.45 P. M. The following papers will be presented: Dr. W. S. Brown, of Stonham, "Early Years' Experience in Midwifery;" Dr. M. A. Morris, of Charleston, "Three Cases of Pelvic Hematoma, one Death;" Appliances will be shown by Dr. M. L.

Chamberlain: An apparatus for the purpose of giving a continuous vaginal douche for pelvic inflammation, and in obstetrical cases; also, an abdominal coil to be used in connection with the above, or separately, whereby continuous heat or cold can be applied to the abdomen. Dr. W. H. Baker, Douche Pan and Pan. Dr. James R. Chadwick, Douche Pan designed by the late Dr. T. B. Curtis. Mr. F. W. Dudley, a Pan invented by Dr. W. M. Seabury, of San Francisco.

JAMES R. CHADWICK, M.D., Chairman.  
ROBERT B. DIXON, M.D., Secretary.

BOSTON SOCIETY FOR MEDICAL SCIENCES.—At a meeting of the Boston Society for the Medical Sciences to be held at the Medical School, Boylston Street, on Tuesday, the twentieth of January, at eight P. M., the subject of Erythroxylon Cocaine will be discussed from a botanical, chemical, and therapeutic point of view, by Drs. Goodale, J. W. Warren, F. H. Williams, and others. Members of the medical profession are cordially invited to be present.

W. W. GANNETT, Secretary.

#### APPOINTMENTS.

BOSTON DISPENSARY.—At the January meeting of the Managers of the Boston Dispensary the appointments of medical officers were as follows: Dr. Herbert L. Barlett, surgeon to Central Office; Dr. Russell Sturgis, physician to Central Office; Dr. E. L. Lombard, physician to the Department for Diseases of Women; and Drs. Thomas F. Sherman and W. B. Bancroft, district physicians.

COMMITTEE OF MASSACHUSETTS LEGISLATURE ON PUBLIC HEALTH.—Senators: Burden of Bristol, Harlow of Middlesex, Emerson of Essex. Representatives: Warner of Worcester, Smith of Andover, Frothingham of Haverhill, Hemphill of Holyoke, Baker of Shelburne, Rust of Boston, Waters of Millbury, Dunforth of Williamstown.

BOOKS AND PAMPHLETS RECEIVED.—A Manual for the Practice of Surgery. By Thomas Bryant, F.R.C.S., etc. With 727 Illustrations. Fourth edition. Thoroughly revised. Philadelphia: Henry C. Lea's Son & Co., 1885.

THE MEDICAL TREATMENT OF DIPHTHERIA.<sup>1</sup>

BY JOHN M. KEATING, M.D.,

Visiting Obstetrician and Lecturer on Diseases of Women and Children.

[Reported for the JOURNAL by WILLIAM H. MORRISON, M.D.]

GENTLEMEN, I propose to-day to call your attention to the medicinal treatment of diphtheria, having previously spoken of the results of the mechanical interference with respiration due to closure of the larynx and of the benefits of tracheotomy in such cases.

The child before you is not suffering from this disease, but at the same time it presents certain features which are characteristic of pharyngeal catarrh, and it is a case which might be mistaken by those not thoroughly posted as to the appearances of the throat in diphtheria for that affection. This child has subacute enlargement of the tonsils, and, in addition, has two ulcers on either side of the anterior half arches in front. These ulcers at times put on a rather angry appearance and are covered with a secretion having the appearance of diphtheritic membrane. But attention to the history, and the absence of general symptoms, should prevent a mistake in diagnosis. There are many cases spoken of as diphtheria that are not diphtheria. On this account, it is difficult to obtain a clear idea as to the frequency of this disease from statistics. I see that in New York, sixty per cent. of the cases of diphtheria reported are dying, and it will be seen from the newspapers that the death-rate from this affection in large cities is always high. This is partly owing to the fact that statistics can be made to prove anything. Many cases are reported as diphtheria that are simply cases of ulceration of the mucous membrane of the pharynx, for ulceration can take place in that membrane as well as in any other. We are all familiar with the ulcerations, such as aphthae, which occur in the mouths of children, and are probably due to some disorder of the stomach. If this ulceration took place on the mucous membrane of the pharynx, it might be attributed to diphtheria, yet occurring in the buccal cavity it is considered of little account. An ordinary case of catarrhal laryngitis from improper food, exposure to cold, or similar causes, in which the parts are covered with secretion, might be mistaken for, and has often been mistaken for, diphtheria. I wish to guard you against this error and to impress upon you the importance of care in making the diagnosis.

Acute tonsillitis is frequently mistaken for it, especially if there be much fever, swelling of the tissues of the neck and pharyngeal catarrh. In other cases the tonsils are usually affected one at a time, though sometimes both become enlarged at the same time, and present an angry appearance and look as if they had depressions or excavations on their surface. They may be covered with a glary mucus, grayish in color, though transmitting

the darker parts of its tonsil, and at times bearing a pinkish hue. This mucus covers a large surface, and often is in large amount. It can readily be removed by applying to it a solution of alum about twenty parts dissolved in a teaspoonful of tinct. ferri chlor. and water, and the surface from which it is removed is smooth and shining, with no abrasions. There is also much depression in this disease. The symptoms remain local, and pass off rapidly under appropriate treatment.

I would refer those interested in this subject to a clinical lecture delivered by myself and published in the *Medical News* for December 23, 1882. I propose to-day to speak more at length on the subject with the added experience of a few years. Diphtheria is attracting more attention on account of the microscopical appearances which are attributed to this disease, and more especially since the publication of the article by Oertel in Ziemssen's Cyclopædia.

In speaking to you of catarrhal laryngitis and true croup, I said that anything which would cause irritation of the larynx, whether it be cold or other outside irritant, or whether it be mechanical or vegetable poison acting directly on the membrane through the blood, would produce a laryngitis more or less severe. If this catarrhal inflammation were severe enough, it would cause secretion upon the surface, which becoming dry and inspissated would exhibit the appearances of a membrane.

The mucous membrane of the larynx is covered with ciliated, columnar epithelium and is placed on a firm basement membrane, which lying directly on the cartilage is capable of distension to only a slight extent by inflammatory exudation. The mucous membrane of the pharynx, on the other hand, is covered with squamous epithelium and is based on soft tissues, and hence inflammation of the pharynx may lead to a great deal of congestion and edema beneath the surface. Where there is true diphtheria or croupous inflammation of the larynx, there is upon the surface a tenacious, organized, fibrinous deposit, which is imbedded firmly in the epithelial tissue and comes directly in contact with the submucous tissue. This deposit is firmly adherent, and when detached leaves ulcers beneath it. In the pharynx, there is considerable swelling, but very little discharge upon the surface. Where an organized membrane is detached with considerable difficulty from the mucous membrane, leaving behind it an ulceration, there is apt to be gangrenous formation and the absorption of septic matter with the development of septicæmia.

It is held, by those who have had experience both in the laboratory and in practice, that the diphtheritic poison is one of two kinds. The first theory is that it is a specific poison coming from the outside, and developing in decomposing sewer-gas, and is capable of causing diphtheria only. It can, however, only act when located on an irritated surface, and hence diphtheria is most frequent in cold, damp weather when catarrhal diseases are most common. When cold and bracing weather comes, diphtheria diminishes. The second theory is that every one has within himself the poisonous matter which causes diphtheria, and that it simply needs a

<sup>1</sup> A clinical lecture delivered at the Philadelphia Hospital, December 10, 1884.

congested throat, foul air, damp weather, or depression of health, to make the germ potent. In every one's mouth the germ or micrococcus is supposed to exist, and under the influence of suitable conditions, to develop, attach itself to the mucous membrane, and be absorbed. Whatever theory we adopt, the probabilities are in favor of diphtheria being a local disease at the onset, having its beginning in the throat. The fact that the throat symptoms are the first which are noted is in favor of this view. The disease begins with slight catarrh, then come chilly sensations, loss of appetite, and extreme prostration, probably indicating that the poison has begun to act on the nervous system. This shows the importance, which is also enforced by experience, of applying early in the disease those remedies to the surface which will counteract the poisonous matter introduced from without.

The medical treatment of diphtheria is of two kinds: First, the use of remedies calculated to strengthen and give a certain amount of resistance to the system; and, second, the application of remedies to the pharynx, larynx, and air-passages, to prevent the further entrance of the poison, to enable the tissues to resist it, and at the same time prevent the secondary result of septicæmia which follows the decomposition of the excessive membrane thrown out upon the surface. My own opinion is that there are two forms of blood-poisoning in diphtheria. There is blood-poisoning resulting from the direct reception of the diphtheritic poison, whatever that may be, into the system; and, second, that which comes from the reabsorption of the purulent decomposing matters found on the surface of the throat. Where there is the foul odor so characteristic of this disease, with the sanious discharge from the nostrils, the enlargement of the glands of the neck, the infiltration of the loose, cellular tissue around the neck, and the great prostration, we undoubtedly have a case of putridity, and in fact the old name for this disease was putrid sore throat. Nasal diphtheria is one of the most fatal of diseases because the deposition of membrane occurs where absorption readily takes place, and where it is very difficult to remove the offensive discharge and apply antiseptic remedies.

Diphtheria is probably one of the most frequent and important diseases of childhood, and it is desirable that proper treatment should be begun early in the attack. If you are called to a child with diphtheria, you probably will find that the most marked symptom is prostration. This is not found in croup. In that affection there will be great difficulty in respiration, with fever and a bounding pulse, but the child will be able to sit up, and will probably die in that position, to the last resisting the interference with the proper aeration of the blood. I am not now speaking of the laryngitis and croup which accompany diphtheria, for the great majority of cases of croup are, in all probability, those in which the diphtheritic poison has irritated the laryngeal mucous membrane, and given rise to croup of a diphtheritic character. As I say, in an ordinary case of diphtheria, you will find the child listless, with relaxed and flabby muscles, and great depression which is characteristic. The probability is that complaint has been made of more

or less pains in the bones, of want of interest, headache, and loss of appetite. At the same time the secretions are all out of order, the tongue is coated, and there may be some slight soreness of the throat. The diphtheritic deposit can take place on the mucous membrane at any point of the pharynx or the respiratory tract. It is usually found on the anterior half arches, in the form of shreds and patches of gray lymph adherent to the surface. It adheres because it is not a simple catarrhal deposit on the surface, but it has attachments to the submucous tissue from prolongations downward. It is probable that the micrococci (or poison) pass from the mucous membrane into the submucous tissue: are then taken up by the lymphatics and distributed throughout the body. This takes place with great rapidity. The extension of the disease may take place in an upward or in a downward direction. In the more severe cases the disease extends upward. Where extension is downward the chances are that sooner or later the question of tracheotomy will have to be considered.

As already stated, two forms of treatment are to be considered; that is, the constitutional and local. The constitutional treatment will be first considered. The patient should at once be put to bed, and, according to the best form of treatment, free action of the various eliminative organs should be established. If the tongue is coated with a brown fur, especially on its posterior aspect, and you learn that the bowels have been sluggish and there is want of appetite, it is well to place the child on small doses of calomel and soda. I have found calomel useful on several accounts. In the first place, it is the mildest form of cathartic which can be given. When given in doses of one twelfth or one sixteenth of a grain every hour, placed upon the tongue, it will promote secretion from the surface of the mucous membrane and produce a gentle movement of the bowels. According to the present views of diphtheria, both calomel and the corrosive sublimate are largely used. There can be no doubt that calomel acts locally, coating the mucous membrane as it is swallowed. In Germany it is recommended to give large doses of calomel with the idea that its action on the mucous membrane will antagonize that of the poison. Six, eight, or ten grains are given, applied directly on the tongue. Although I would not recommend that calomel be used universally, I would suggest its use in those cases in which it is appropriate. It will weaken the child less than any other form of purgative, and, at the same time, exert a favorable action on the organs of elimination, removing the ashes, so to speak, which have accumulated.

The next important point is in regard to nourishment. At the present time we are probably running into extremes as regards nourishment. As soon as a patient is put to bed we begin to stuff him. In olden times the course was exactly the reverse. The patient was put to bed and starved. Let us take the medium course, watching the patient from the start, without pushing the food until the patient is able to digest it. Bear in mind this axiom: it is not the amount of food which is placed in the stomach, but that which is digested and assimilated that goes to the nourishment of the

tissues. That form of food which is most easily assimilable is the one that should be given. Recently beef peptones and peptonized milk, in which the food has been acted on by the "extractum pancreatis" before being taken into the stomach, have been much used. I cannot urge the use of these preparations too forcibly, as I have been so often been a witness of their value. Peptonized milk punch, milk gruel, and beef tea, having undergone the same preparation, are of incalculable value, and I would refer you to the excellent articles by William Roberts, F.R.S., on this subject. Such foods are of great service. Beef tea made in the old-fashioned way, by acting on the meat with a few drops of hydrochloric acid, for several hours, is of value and is readily absorbed.

The remedies employed should be such as will strengthen the system to resist the action of the poison. Some believe in the free use of quinine. In these cases quinine has no direct influence on the disease, but acts simply as a tonic. If necessary, the sulphate of quinine may be given in small and frequently repeated doses. The patient is to be at once placed on the use of milk punch, for we know that in all probability alcohol acts directly on the germs of diphtheria and it has a direct effect on the nerve centres, preventing the depressing influence of the poison. The experience of those who use alcohol largely in the treatment of diphtheria teaches us that it is probably one of our best remedies.

Corrosive sublimate is also used from the very commencement of the attack, beginning with small doses and increasing it as it is tolerated. This is a dangerous drug, and care must be exercised that the patient be not salivated. It has, however, been found that when a child needs a mercurial of this kind, it can take it in large doses for a long time without the development of unpleasant symptoms. Children with syphilitic disease exhibit a marked tolerance to corrosive sublimate. It is said that this same resistance is seen in diphtheria. In a child of five years, which is the usual age at which diphtheria appears, the beginning dose of corrosive sublimate would be from the one hundredth to the one eightieth of a grain every three or two hours in solution, gradually increasing the dose to the one twelfth or one tenth of a grain as the symptoms demand. I do not present this as a routine treatment, but in severe cases it has been found that alcohol and corrosive sublimate are probably the most efficient remedies in the treatment. In my own practice I have for some time used the bichloride of mercury with most excellent results. In fact I consider it the most valuable remedy that we have for the treatment of diphtheria. I used it a couple of years ago in a very severe case of diphtheria, both internally and directly applied to the throat, and, at the same time, examined, with Dr. Formad, the blood of my little patient daily for micrococci. The latter were in abundance and the case opened badly, but in a short time the child began visibly to improve, the micrococci to diminish, and their action on the white corpuscles ceased, and we could only attribute these results to the free use of brandy and the increasing doses of corrosive sublimate.

I shall next refer to the use of iron in these cases. Where there is a foul tongue and clogged portal system, the use of iron is contra-indicated. After the action of the bowels has been established, the patient may be placed on the tincture of the chloride of iron, gradually increasing the dose until a sufficiently large dose be given. It is to be remembered that although the iron is given, yet it may not be absorbed, but pass off through the bowels without accomplishing any good effect, hence the stools should be watched to see that the remedy does not pass off in this way.

The administration of the vegetable acids has been highly recommended in these cases, and as we know lemon juice, orange juice, and the like are valuable in all forms of low condition of the system with blood-poisoning. In France elaret is given freely. I have used it both internally and with chlorate of potass. and salicylic acid as a gargle, with excellent results.

The patient should be given fluids freely. It is advisable to let him drink some liquid which is nourishing. Whey made with wine is to be recommended if the child needs it, or the white of egg mixed with water (to which may be added a vegetable acid, as lemon juice) may be employed. If these drinks do not agree with the stomach, simple water may be used.

The next subject to be considered is that of the local treatment. Until recently there were but few applications to be made directly to the throat. There are two ways of bringing remedies in contact with the affected tissues in this disease. One is by means of the brush, and the second is by the use of the steam atomizer. Where there is acute inflammation of the throat no very irritating substances should be applied. Astringent gargles are of service where they can be used. I have used chlorate of potassium with success. Ordinary table salt may be combined with this, and it is an advantage to add salicylic acid. The patient may gargle his mouth with this, and the same solution may be used for swabbing out the throat every hour or two. If there is distinct evidence of deposit on the half arches and the tendency is for the deposit to increase, the use of astringent preparations should be at once begun, in order to cause contraction of the capillaries and prevent further absorptions. For this purpose the following preparation is of service:—

R Tinct. iodini . . . . .	5j.
Tinct. ferri chloridi . . . . .	5j.
Acidi carbonici . . . . .	grs. x.
Glycerinae . . . . .	3ss.
	M.

This may be gently applied to the surface with a camel's-hair brush once or twice a day, and should be done by yourself. Preparations of tannin may also be used. One of the best of these is the glycerole of tannin. The preparation ordinarily known as Bell's gargle for syphilitic cases, which consists of compound tincture of cinchona to which is added corrosive sublimate, may be used. Oertel, in the article already referred to, recommends the use of poultices to the surface of the neck, in order, if possible, to produce congestion and suppuration of the submucous connective tissue, believing that this will prevent the absorption of the diphtheritic

poison. It is by suppuration alone that the membrane is thrown off. If the membrane is adherent, it should not be detached by force, for this causes irritation and leaves an abraded surface. The endeavor should be made to act on the tissues beneath the membrane, in order to promote its spontaneous separation. The cold-water compress, or handkerchief covered with oiled silk, or waxed paper, is an excellent application to the throat.

Delhill, of Paris, has lately strongly advocated gas coal-tar fumigations in this disease. Inhalations of kerosene have been used in this country as an "old woman's" practice, and have received trustworthy endorsements. These are only other forms of antiseptic treatment.

Recently the attempt has been made to dissolve the membrane, especially after tracheotomy. Some believe that the application of bicarbonate of soda in powder on the surface liquefies the membrane and favors its expulsion. Others believe that the use of turbid lime-water and liq. potass. with the steam atomizer will dissolve the membrane. This has been especially recommended by Dr. J. Lewis Smith, of New York. Pepsin has also been tried, but as pepsin only acts in an acid solution it cannot be of much service in this affection on account of the difficulty of applying acid solutions to the throat. At the recent meeting of the New York State Medical Association Prof. Lewis Smith read an interesting paper describing cases in which he had used trypsin as a local application for the purpose of dissolving diphtheritic membrane. This is one of the active principles of the pancreatic fluid. It is the pepsin, so to speak, of the pancreatic secretion, and only differs from pepsin in the fact that it acts in an alkaline as well as in a slightly acid solution. Trypsin, at present, is not in the market, but it was suggested by the author that the "extractum pancreatis," of which the trypsin is the most active ingredient, could be used in this way, taking, for instance, a mixture of extractum pancreatis and sodium bicarbonate, or turbid lime-water, and applying it by means of an atomizer. The theory is that by using trypsin in solution with bicarbonate of sodium or lime-water with the atomizer, the membrane will be digested and the surface freed from its presence, and then by the use of quinine, iron, and tonics, its further formation will be prevented.

Various other substances may be used with the atomizer. Dobell's solution is valuable, and may be used as a vehicle for other remedies. It may be prepared according to the following formula:—

R Sodii bicarb.	an grs. xx.
Sodii chloratis	grs. ij.
Acid carbolic	℥j.
Glycerine	℥j.
Aque	℥ss. Solve.

I have also used listerine in these cases. This is a proprietary preparation, yet at the same time we know its formula, and it is a valuable antiseptic. Thymol may also be employed dissolved in alcohol of the strength of from one to ten parts in the thousand, according to circumstances.

The local remedies should be applied frequently in these cases, and it is the duty of the physician to see that the applications are properly made, and when possible by himself.

I have great faith in the use of the permanganate of potash for washing the throat and naso-pharynx. You should use a solution well colored, applying it to the nose through Politzer's bag or the douche, and mop out the throat every hour or two. At least every hour should some application be made to throat. Choose that preparation in which you have the greatest confidence, and there are many to select from, and then make out daily a schedule of your case, dividing the nourishment, such as milk, soup, peptonized gruel, meat-jellies, etc., so that, although the quantity be small, your patient will get something every hour. Give brandy or whiskey or wine in doses which you think sufficient, judging by the pulse, the temperature, and the patient's condition, and remember that in bad cases stimulants can be given in large doses, and, indeed, should so be given, for alcohol in such conditions is your sheet-anchor. It acts as a stimulant, probably as a germicide, and it prevents tissue changes. It can be given with cracked ice or in the form of punch. If the milk punch is heavy, add plenty of lime-water to it, or peptonize the milk beforehand. Spray the throat with either turbid lime-water, Labarraque's solution, or use a steam atomizer, with Dobell's solution. If the patient be old enough, a perforated zinc respirator (Coquet's) may be used, and kept constantly on the face. Upon the sponge of this may be placed a few drops of eucalyptol, or, possibly, the iodide of ethyl, as recommended by Dr. Cohen. I have never used the latter.

Quinia can be given in the form of suppository, using the sulphate and avoiding the bisulphate, as the latter will occasionally irritate the bowel.

Test the urine frequently for albumen, and if it is found encourage your patient to drink freely of some diuretic water, such as Lithia water, and give Basham's mixture, if the stomach will tolerate it. Keep the patient warm, and sponge daily. I would advise you to generate some chlorine in a saucer in the room, or to saturate cloths in some reliable antiseptic, and allow evaporation to take place in the room.

## A CASE OF ABDOMINAL TUMOR.

BY WILLIAM L. RICHARDSON,

Visiting Physician to the Massachusetts General Hospital.

THE case to be reported is one interesting from the obscurity which at times made the diagnosis at least doubtful. The improvement which followed the opening of the abscess; the comparative freedom from pain, rendering the administration of opiates unnecessary until with a few days of the fatal termination; the apparent diminution in the size of the abdominal tumor during the last few months; the sudden, and in one sense fortunate, occurrence of a fatal peritonitis, unaccompanied by any rise in temperature, the result apparently of an accident, — were the symptoms worthy of record.

Mr. D., merchant, sixty years of age, married, first consulted me January 31, 1883. He was a man over six feet in height, with an average weight of 195 pounds. Family history good. Temperate as regards the use of alcohol, and also tobacco, except occasionally, when he smoked considerably. He had always enjoyed excellent health, and

appeared then to be in good condition. In the fall, or early winter, of 1881 he had fallen from a pile of lumber, striking his neck and right hip on a projecting log. The accident, however, proved not to be serious, and in a short time was forgotten. When I first saw him he stated that, while his general health was good, he had not felt quite up to the mark the last two or three years, although he could not tell just why he had not. For many years he had been troubled with constipation, and since the spring of 1882, nearly a year before I first saw him, he had complained at times of his stomach and bowels, especially the latter, and of a more or less persistent and troublesome backache. The bowels had been more than usually constipated, the food seeming to be arrested at a spot below the ribs on the right side. Flatulence and distress at times after eating made up the list of his complaints. His general appearance was that of a man in good health, although he stated that he had lost several pounds during the last few months. He had a good appetite and slept well. The urine was normal. A physical examination detected a tumor in the upper part of the right iliac region, about the size of a small flattened orange, slightly tender on deep pressure. A regulated diet, tonics, laxatives, and comparative rest and freedom from daily business engagements were ordered. Under this treatment there was a decided improvement in the intestinal and gastric symptoms, but although his appetite improved he did not gain in strength, and his weight gradually decreased.

A month later the tumor had increased somewhat in size, and was more tender; the flatulence and occasional distress after eating became more troublesome, and he soon found the recumbent position on the bed or sofa the most comfortable. The diagnosis was made of cancer, though its exact anatomical position was doubtful. At my request Dr. F. Minot saw the patient with me in consultation March 1st, and agreed to the diagnosis and treatment. Early in March the services of a nurse were called in requisition, as he was obliged to take his food frequently and in small quantities, and he complained of more or less pain at intervals in the right iliac and epigastric regions.

March 18th. He was uncomfortable all day, there being a steady aching in the bowels, and occasionally a sharp pain in the region of the tumor. He was unquestionably weaker, and his appetite was poor. Stimulants were added to the former treatment.

March 23d. He remained in bed all day for the first time. He was unable to lie on the right side on account of the pain caused by that position. The temperature was normal.

March 29th. His weight was 165 pounds, showing a loss of between thirty and forty pounds. He complained frequently of distress in the right side, and his nights were restless, although he would occasionally sleep the greater part of the night. He was unable to walk without assistance, owing to general weakness.

April 5th. During the afternoon he had a great deal of abdominal pain in the neighborhood of the tumor, and extending toward the umbilicus, which also prevented his sleeping at night.

April 11. The temperature for the first time began to rise, and for two days reached the neighborhood of 102° F.; the tumor was more tender, and had increased somewhat in size. For a week past he was unable to lie on the left side, as such a position invariably started up a pain in the region of the tumor. From this time poultices were ordered from time to time *pro re nata*. The next week was one of improvement, his appetite being decidedly better, and his strength such as to allow him to sit up several hours a day. He gradually became able to rest on his left side.

April 25th. After sleeping an hour and a half, he awoke feeling chilly, and soon after had a well-marked rigor lasting half an hour.

April 26th. After taking a compound rhubarb pill he had a loose dejection containing a small amount of blood and pus. The tumor felt flatter, but more extended, reaching nearly to the groin, but was tender only on deep pressure at the lower border. The evening temperature for several days ran over 100° F., and the inguinal glands became enlarged and tender. He was again obliged to lie on his back, either lateral position causing him much pain.

May 9th. Dr. C. D. Homans saw the patient in consultation, and agreed to the diagnosis of cancer. His appetite had decidedly improved, and he was fairly comfortable; occasionally a trace of blood and pus was seen in the dejections. His nights were, as a rule, good, and his great complaint was of a dull ache in the region of the tumor, and of weakness.

May 30th. His days and nights had been better for some time. His appetite was excellent. The tumor was enlarging, and he complained of a feeling of constriction when he breathed.

June 4th. For the last four nights he had been obliged to sleep bolstered up, on account of dyspnea on lying down. There was considerable clotted blood in some of the dejections.

June 9th. The record reports him as doing well. Sits up most of the time, and walks about without assistance. Has a good appetite, no pain, and sleeps well at night, lying on either side.

June 13th. He walked downstairs and back again without assistance.

June 15th. At his request a careful examination was made of the tumor, and the following statement given him to send to an intimate friend in a distant city: "A malignant growth within the abdominal cavity, about and below the region of the liver." This opinion was concurred in by Drs. F. Minot and C. D. Homans.

June 17th. There was a decided redness, swelling, tenderness, and a questionable feeling of fluctuation over Poupart's ligament.

June 20th. The redness had somewhat disappeared, but the swelling had increased in size, though much less tender to the touch.

June 26th. He was feeling decidedly better, was able to dress himself, and went down two flights of stairs for his dinner, feeling no fatigue from the exertion.

June 28th. I saw him for the last time before going to Europe for the summer. He had been downstairs to his meals the last two days, and was

feeling much stronger. The tumor was larger, and in one place fluctuating. Dr. C. D. Homans now took charge of the case during my absence.

July 1st. After walking across the chamber and sitting down in a chair he was suddenly seized with a sharp pain in the right iliac region, and felt as if something had given way. The pain soon subsided, and he had a very comfortable night.

July 5th. He was etherized, and, after a careful examination of the tumor by Drs. C. D. and John Homans, the former made a free incision about one and one-half inches long over the fluctuating point; a small amount of pus escaped from the wound, but the next day about a pint of pus was discharged. His appetite improved, and the pain and general discomfort from which he had so long suffered were greatly relieved. The wound discharged freely for several days.

July 17th. Twelve days after the operation he was able to walk from one room to another, and seemed to be, in every way, decidedly improving; the discharge from the wound was very slight, about an ounce a day.

July 20th. He was carried downstairs, and went to ride.

July 24th. He was able to walk downstairs. From this time the record was one of gradual improvement in spirits, strength, and appetite. The tumor had greatly decreased in size, and was tender only on deep pressure. The discharge from the wound was very slight, and of a sero-purulent character.

August 17th. He went to Wellesley, where he remained until September 13th. While at Wellesley he came in town twice on business. He preferred to walk during the summer and fall, as the jolting of riding occasioned him some pain in the old spot.

Soon after I returned from Europe, in October, he walked into my office, and seemed in remarkably good spirits. He stated that he was at times well, but frequently had days when his back and side ached, and the bowels were very irregular in their action, there being at times considerable flatulence and abdominal discomfort. I saw him occasionally from November until the latter part of January, 1881, when, owing to increasing distress and weakness, it became necessary to again secure the services of a nurse, and my attendance became frequent. The old wound still continued to discharge a slight amount of a sero-purulent fluid. There was considerable tenderness along the crest of the ilium. It became a question whether there might not be some necrosis of the pelvis resulting from the fall in 1881, to which allusion has already been made, but a probe failed to detect anything in the way of dead bone at the end of the old tract.

During the early part of April he began to complain a great deal of periodic chilly attacks, and the evening temperature was about 100° F.

April 15th. The discharge having become decidedly purulent in character and greater in amount, the patient was etherized and a drainage tube was passed by Dr. C. D. Homans through the opening and out at the back just above the line of the crest of the ilium. The wound was syringed daily with carbolic water.

April 30th. The tube being stopped up, it was

changed for a larger one. His weight, May 7th, was 164 pounds, which was the same as he had weighed about a year before. The tube was removed May 19th, but the carbolic washings were still kept up through the wound. The next day he was able to go downstairs.

May 30th. He awoke with severe pain in the hip and leg, which soon became swollen and somewhat tender.

June 1st. The whole leg was swollen, and there was marked tenderness along the line of the femoral vein. This tenderness gradually subsided, as did also the swelling, although the leg never regained its natural size.

June 9th. He went out on the roof of an L, which was back of his chamber, on which a hammock had been hung, and there he passed more or less of the days during the summer. The right leg became again swollen, tense, and tender, and at times there was distress in the region of the tumor, which had not increased in size, but had grown firmer to the touch and much less tender than formerly. By the early part of September he was feeling much better, his appetite was good, the leg no longer troubled him, and his poor days were the exception rather than the rule. He was very cheerful and bright, and his nights were good. The tumor had apparently diminished in size.

September 10th. He awoke feeling very bright, and spent the day as usual in the hammock. In the afternoon, during the temporary absence of the nurse, wishing to get something from his chamber, he attempted to get in through the window, but slipped, and felt a sudden pain in the region of the tumor. Soon after he complained of great distress and pain in the abdomen. Having left the city for the night, and Dr. C. D. Homans being also absent, Dr. John Homans was called and ordered an opium suppository of two grains. This was the first opiate he had ever taken. It was repeated in an hour, but without relief, and chloroform was then given. He fell asleep, but awakened at intervals during the night complaining of general abdominal pain.

The next morning, September 11th, I found him quite drowsy. He was suffering a great deal of pain, but not enough to make him willing to take any more opium. The temperature was normal. Toward evening the abdomen began to be tympanitic.

September 12th. The nurse reported that he had had a poor night; about half past seven o'clock in the morning he had a very severe attack of pain, and Dr. J. Homans was again sent for. Morphia subcutaneously failing to give any relief, the patient was etherized. At the time of my visit he was comparatively free from pain, but very restless; there was marked tympanites; no tenderness except immediately over the tumor; the temperature was normal. The pain returned at intervals during the day, requiring the administration of ether. After ten o'clock in the evening the pain ceased, but he was still very restless, and he died about two o'clock on the morning of the 13th. The autopsy was made by Dr. W. W. Gammett, the subsequent day, with the following result:—

Externally, there was a fistulous opening, large enough to admit the forefinger, in the right groin, two cm. above Poupart's ligament and four cm.

to the outside of the middle of this ligament. There was also a similar opening behind, just above the crest of the right ilium. A bougie passed into the anterior opening emerged at the posterior one.

The points of special interest in the internal examination were a recent, diffuse, fibrino-purulent peritonitis due to a perforation in the anterior wall of the cæcum, with escape of the intestinal contents. This perforation corresponded to the centre of one of several cancerous growths to be presently described.

On opening the cæcum and ascending colon there were found on the anterior and posterior walls, but more abundant on the latter, a number of elevated papillary structures, about three cm. in width. These showed a central depression and an elevated, circular periphery, hence presenting a crater-like appearance. Those situated posteriorly had a central opening connecting the lumen of the intestine with an irregular, trabeculated multilocular cavity lying behind the cæcum and first portion of the ascending colon. The walls and trabecule were made up of a rather dense, grayish tissue, showing numerous opaque grayish-yellow points; from the latter drops of a thick fluid issued when pressure was applied. In the larger spaces was a small amount of a puriform fluid. The cavity connected not only with the intestine but also with the external openings previously described.

The dense tissues behind the cæcum showed, microscopically, a basis substance of connective-tissue fibres enclosing spaces, the latter being filled with cylindrical epithelial cells, atypically arranged. Hence the mass was a cylindrical cell cancer.

The probable sequence of events was, primarily cancer of the cæcum extending into the deeper tissues posteriorly; then necrosis of the central portions, affording ingress of intestinal contents; then suppuration in the new-growth, as shown by discharge of pus from the rectum early in the disease; then sufficient pus forming behind the cæcum to require artificial opening. Finally the perforation of one of the cancerous nodules situated in the anterior portion of the cæcum: so escape of intestinal contents and a fatal peritonitis.

#### REPORT OF A CASE OF OCCLUSION OF THE VENA CAVA SUPERIOR, AND OF A CASE OF HEART-TUMOR.<sup>1</sup>

BY ARTHUR V. MEIGS, M.D.,

*Physician to the Pennsylvania Hospital.*

A MAN seventy-two years of age was admitted to the Pennsylvania Hospital on September 18, 1883, and gave the following history: For thirty-five years he worked as an iron-moulder, but during the past year he has been gaining his living as a pedlar. He was always very strong and well until during the last two years, when he has had some pain in the lumbar region which has increased in the last three weeks, and during that time he has not slept well. The day of his admission

he was standing by the edge of the river looking at some object upon the water, when suddenly, and for the first time in his life, he was seized with vertigo, and fell into the water. When brought to the hospital the following was noticed as to his appearance and condition: He is tall and spare, having lost much flesh in the last few years, and stoops moderately. The skin is slightly yellow and the tongue furred. The radial arteries are markedly stiffened. The veins on the right side of the abdomen and chest are enlarged, the largest being half an inch in diameter; those upon the left are comparatively slightly enlarged. Prominent veins extend also toward the right axilla. He cannot say how long these veins have been enlarged, as he never gave them any thought, but is sure that they were not always so. Examination of the heart reveals a murmur which precedes the impulse and the carotid beat. There is slight visible impulse in the epigastrium. At the base of the heart, the sounds are almost inaudible, but they can be heard beneath the sternum; no accentuation of the second sound can be distinguished at the base, although at the apex the second sound is loudly accentuated. The hepatic dullness in the nipple line begins at the sixth rib, and extends slightly below the costal arch. The radial pulse is irritable, but the beat is not increased when the arm is elevated.

September 21st. It was noted, the cardiac impulse is in the fifth interspace two inches to the left of the sternum and is rather feeble; there is somewhat more forcible impulse beneath the lower end of the sternum and some visible throbbing of the abdominal aorta. Percussion one inch to the left of the sternum shows the cardiac dullness to begin in the third interspace, and there is flatness at the fourth rib level. Transverse percussion at the fourth rib level shows dullness, beginning at mid-sternum and extending to the left about four inches. There is distinct impulse in the second interspace to the left of the sternum, and this appears to precede the apex impulse; there is also impulse in the second right interspace, which also precedes the apex beat. There is dullness on percussion in the first interspace to the right of the sternum and in the third interspace. The percussion resonance at the corresponding areas on the left side is natural. There seems to be impaired resonance upon percussion over the upper part of the sternum. The presystolic murmur at the apex is distinct. At the pulmonary area the sounds are very faint but distinct, and the same is the case at the aortic area. At the ensiform cartilage both sounds are distinct, but the first is rather thumping, and is accompanied by a faint blowing murmur which is synchronous with the beat of the carotid artery. There is no undue pulsation of the arteries of the neck, and the veins are full but do not pulsate. There is a systolic murmur in the carotids which is increased by pressure; this is also distinct in the subclavians. There is marked systolic murmur in the femorals and in the abdominal aorta as low down as the umbilicus. Lung examination shows slightly impaired percussion resonance at the right apex, while the note is full at the left. The respiratory sounds are slightly more feeble at the right than at the left apex. Posteriorly the percus-

<sup>1</sup>Read before the College of Physicians of Philadelphia, December 3, 1884.

sion note is short, but not markedly dull. The respiratory sounds are unusually feeble.

September 23d. The radial pulse is delayed. Pressure upon the enlarged veins at the lower third of the sternum causes the portion of them below the spot pressed upon to become less prominent and full, and produces a sensation of fulness over the eyes. The veins in the right iliac region tend to be enlarged.

September 28th. When the patient is in the erect position, the veins on the left side of the chest between the nipple and the sternum are enlarged. The collection of veins is somewhat cone-shaped, and extends from the umbilicus to the ensiform cartilage, the base being at the umbilicus, which it partly surrounds. The veins going toward the axillæ and those upon the upper part of the sternum are also enlarged. Measurement of the chest on a level with the nipple shows a circumference of thirty-three and five-eighths inches. During ordinary quiet breathing the chest expansion is only one eighth of an inch, and the extreme expansion on forced inspiratory is only one inch. Percussion gives a sound almost dull over both lungs anteriorly and over the upper part of the left lung posteriorly; over the lower portions the note is fuller, but still very short. Anteriorly the respiratory murmur is exceedingly feeble on both sides, almost wanting on the left. Posteriorly the respiratory sounds are very feeble, more so above than below. The treatment consisted at various times of iron, iodide of potassium, and strychnia. During the whole time that he was in the hospital he complained bitterly of vertigo, and finally became very much disheartened, and on the morning of December 12th cut his throat, severing the left external jugular vein. After he had lost a great deal of blood, the vein was ligated and he lingered until December 20th, when he died.

The clinical history was taken by Dr. Charles Baum, and I am indebted to Dr. Da Costa for the opportunity of continuing the history of the case after I gave up the charge of the ward. The post-mortem examination was made and the note of it furnished by my colleague, Dr. Longstreth, who is pathologist to the hospital. It was the resident physician, Dr. W. J. Taylor, who first drew attention to the facts that pressure upon the enlarged external veins caused a sensation of fulness in the head and suffusion of the eyes, and that the blood current was downward in these veins, and it was from these symptoms principally that I was enabled to make the diagnosis.

*Autopsy.*—The first step in the examination was to inject the venous system. An opening was made on the right side of the neck, and the large vein was raised up in the middle cervical portion. The injection matter used was gelatine colored with carmine. The mass flowed with comparative ease, and was very soon seen flowing and distending the superficial enlarged venous branches over the front of the thorax, at its lateral parts, and at and around the umbilicus.

Allowing time for the warm mass to harden, the examination was continued by dividing the ribs and clavicles in the line of the nipples, and separating the whole mass of the anterior abdominal muscles

from the skin. Raising up this anterior mask of the thorax and abdomen, the abdominal aorta and the inferior vena cava were dissected free; the stomach, liver, and diaphragm were freed from their posterior attachments. In the neck, all the vessels and muscles, together with the trachea and œsoph-

FIG. 1.

agus, were raised up. In the thorax the conjoined organs were cut free from the vertebrae. Thus, the whole mass of organs from the thorax and abdomen were removed *en bloc*, and their dissection was proceeded with from the posterior aspect.

In the left pleural cavity, placed superficially just beneath the membrane, was seen a large venous trunk about half an inch in diameter, situated on the bodies of vertebrae and extending from the arch of the aorta to the attachment of the diaphragm below. This vessel was the left azygos; it was on the left side of the aorta. In dividing the tissue of the posterior mediastinum, the veins of communication between the spinal and intercostal vessels were found unusually large, from one third to half an inch in diameter, and were thus in condition to carry a large amount of blood from the upper part of the trunk and the head downward to be emptied into the abdominal vena cava. On removing the organs, the injecting material was found to have filled the veins to the arms and neck on each side, the spinal and intercostal vessels in the thoracic portion, numerous large veins in the diaphragm, converging directly toward the inferior vena cava, and also the abdominal portion of that vessel.

In dissecting the neck, numerous large veins (several quarter of an inch in diameter) were found passing behind the trachea, and they served as a communication from the right to the left side. They commenced at about the level of the episternal

notch and descended into the thorax passing toward the left, and terminated in the beginning portion of the left innominate or transverse vein. The left innominate vein at this part was very much enlarged, and as the vessel advanced toward the right side to join the vena cava, it was found to be converted into a flattened fibrous cord, and this portion was pretty tightly adherent to the surrounding tissues and the branches from the arch of the aorta lying in contact with it.

A probe passed downward within the right jugular was stopped by an obstruction at a point where the right innominate vein joined the fibrous cord in which the left innominate terminated. From the posterior wall of the right innominate, the probe entered the mouth of a moderate sized vessel which passed downward into the thorax; its termination and communications could not be traced; it was supposed to communicate with the right azygos vein, but this vessel could not be found.

On removing the heart the pericardium was found normal. The heart was large; its weight was not taken, as a considerable portion of its auricles were left in connection with the specimen. Both the right and left ventricular walls were thicker than normal.

The mitral orifice was narrowed at its auricular aspect, but its outlet in the ventricle was of normal size. The anterior segment was rendered rigid by the deposit in it of calcareous matter. This deposit extended from near the free border, centrally through the leaflet and terminated within one of the cusps of the aortic valve. The mitral orifice was thus not only partially obstructed, but the auricular aspect of the leaflet was roughed by the calcareous nodular deposit.

The aortic cusps were all three materially affected; one was rendered rigid through one half its depth by the calcareous deposit extending from the mitral valve, another cusp showed a slightly projecting ridge of deposit on its ventricular aspect along the line of junction with the opposing cusp, of firmly organized fibrous material, while the third cusp was thickened, less pliable than normal, but smooth.

The other orifices and valves showed nothing especial to note.

The opening of the inferior vena cava appeared larger than normal, perhaps half as large again. The opening of the superior vena cava was found obliterated. A very fine probe could be forced in, by tearing tissues at the normal site of the cava, about an inch. It was found, therefore, that the obstruction existing above in the innominate vessels was complete, and extended to the auricle.

The aorta and its principal branches were very much diseased. Commencing at the aortic orifice, the whole vessel was somewhat dilated, though not aneurismal, and this condition extended to the abdominal portion. Its walls were thicker than normal and very rigid. In most parts of the tube atheromatous changes with calcareous degeneration had taken place, so that in squeezing the vessel between the fingers the calcareous deposits cracked under the pressure with a gritty sound.

The cause of the compression and final obliteration of the calibre of the superior vena cava with its branches seemed to be due to the rigidity of the

aorta, together with condensation of the surrounding connective tissues, probably of inflammatory origin. All the connective tissue around the arch of the aorta and first portion of its principal branches was increased in amount, and very dense, and firmly adherent to the under surface of the sternum, as well as posteriorly to the bodies of the vertebrae. It was in this tissue that the obliterated venous trunks were found, and to which the tissue adhered so firmly that it was difficult to separate the two in dissection.

The venous blood from the head, upper extremities, etc., found its way to the heart by means of the greatly enlarged veins lying on and around the spinal column posteriorly, particularly the left azygos, as well as anteriorly through the enlarged internal mammary vessels and the superficial thoracic and abdominal branches. Most of the blood evidently came downward to the level of the diaphragm, and thence found its way directly into the inferior vena cava. Other portions of the blood descended from the superficial portions of the thorax into the abdominal vessels, and thence by the lumbar branches to the abdominal vena cava.

The examination of the brain showed a notable fullness of the vessels of both the external and the internal membranes. Small patches of opacity were found on the arachnoid in some places, along the line of the sulci over the convexity. Some of the convolutions showed in places slight degrees of atrophy, and the furrows between them were widened, and at these parts there had accumulated a small amount of clear subarachnoid fluid.

FIG. 2.

Rough diagram showing collateral circulation.

The brain substance showed no especial alterations. The vessels of the circle of Willis presented themselves as India-rubber-like tubes, patulous and rigidly elastic. No calcareous degeneration of their tunics was found. The same conditions were visible in the beginning portions of the principal branches leading from the circle.

This case was a rare one, and of more than usual interest for several reasons. In the first place, there were unusual opportunities for studying the conditions, both ante- and post-mortem, and the physical signs were such that the diagnosis was made during life. The enlargement of the veins of the surface led to the suspicion that one of the cavæ was occluded, and it was decided that it must be the cava superior, because when the large external veins were emptied for the space of an inch or two with two fingers the blood evidently flowed much more rapidly and forcibly downward when the finger nearest the head was first removed than it did upward when the lower finger was first removed, and this was the case as much when the patient lay in bed as when he stood, thus showing that the current in the enlarged external veins was downward. Further reason for thinking that the return circulation from the head found its way back to the heart partly by the external veins was that if they were compressed there was at once produced visible congestion of the veins of the face and suffusion of the eyes, and a sensation of fulness in the head. The presystolic murmur in the heart was very marked and unmistakable, and at all times present while the patient was under observation, and abundant cause for its presence was found in the calcareous deposit, with stiffening and roughness of the anterior flap of the mitral valve. The systolic murmur at the base of the heart and in the arteries was caused by the stiffening and roughness of the aortic valve flaps and of the thoracic and abdominal aorta. It was suspected during life that the arteries of the brain would be found to be stiff, and this was the case; still it is very likely that the vertigo with which the man suffered, and of which he complained more than of any other symptom, may have been partly due to the obstruction to the return circulation from the brain caused by the blood having to find its way through much smaller and more tortuous routes than the natural ones, and this view would seem to receive further confirmation from the fact that there was found some flattening and shrinking of the brain convolutions. The cause of the dulness on percussion over the upper part of the right side of the chest anteriorly and the upper part of the sternum, which was so distinctly made out, was not understood during life, but the post-mortem showed abundant cause for it in the very great amount of hard fibrous tissue around the ascending aorta and veins in that region, and here, apparently, was the seat of origin of the whole pathological process. It seems most likely that the changes which finally caused a complete occlusion of the whole of the vena cava superior and the larger portion of both the innominate veins had its origin in a periarteritis which must have begun around the ascending or transverse portion of the aorta. This must have proceeded gradually, with a constant increase and condensation of the tissues around the aorta and veins until at last there was produced the large amount of hard fibrous tissue which the post-mortem examination showed to exist in that region.

A man twenty-six years of age was admitted to the ward July 21, 1880. No history of previous

disease was obtained, except that he had frequent attacks of ague, and eighteen months ago had typhoid fever. One year ago he had a chancre, but it was followed by no secondary symptoms. In March (four months ago) he was upset from a boat, and after being two hours in the water was taken out unconscious. Since that time he has noticed that he has had more or less shortness of breath, but felt fairly well, and was able to be about until one week ago, when his left arm became paralyzed, and the next day the leg became weak, so that he walked with difficulty. Upon admission he was suffering very much from dyspnoea, and his breathing was very rapid, being forty-eight per minute. The pulse was frequent and weak. In walking he dragged the left leg, and the arm on the same side hung powerless, and was much swollen and oedematous, both feet and legs being also oedematous. The face was drawn to the right, the muscles of the left side being flaccid, but the tongue was protruded without deflection to either side. The speech was rather mumbling. The urine was normal.

July 22d. A more careful examination of the heart revealed a faint mitral systolic murmur, and that the heart was hypertrophied. There were numerous coarse moist râles audible over the lungs, and there was evidence of some pleuritic effusion.

July 23d. Condition much the same, but he is more stupid, and has frequent attacks of dyspnoea.

July 25th. He is unconscious, and passes his urine in bed. The heart murmur is more distinct.

July 26th. Is sinking, and died July 27th.

Post-mortem examination showed the pleural sacs to contain slightly over a quart of clear serum, and that the heart was much enlarged. The fluid and enlarged heart occupied so much space in the thorax that the lungs were much compressed; they felt firm to the finger, but were crepitant throughout, although they were not more than half the natural size. The heart was both dilated and hypertrophied. The right side showed nothing of interest, the valves being normal. The left ventricle and auricle were both much dilated and hypertrophied; this condition was very marked in the auricle. The mitral opening was narrowed, the valve flaps being stretched across it. When looked at from the auricle there was seen a tumor springing from the posterior flap of the valve and projecting into the auricular cavity, which was about three quarters of an inch to an inch in diameter, and about half to three quarters of an inch in height. This mass was made up of two different layers, the lower smooth and rounded, and the upper rough and uneven, and there were numerous little shreds like rootlets hanging from its surface. There was also on the anterior flap of the valve a spot which was much roughened, and had minute vegetations attached to it. This was probably due to ulceration from friction against the tumor on the other cusp. The aorta was narrow and the valve flaps much thickened, so that the valve was incompetent. The liver was about natural in size, but the capsule was much thickened. The spleen also was natural in size, but rather firm, and its capsule thickened. The kidneys appeared natural. The brain presented considerable softening of its right side; this was of the lower parietal lobule and the upper adjoining

part of the temporo-sphenoidal lobe; there did not appear to be any involvement of the motor tract. Upon examination of the middle cerebral artery it was found to divide primarily into three branches. The first of these was patulous, but the two posterior ones were blocked with emboli.

Dr. Simes sent me the following report of the results of an examination of the tumor:—

"I have made a microscopical examination of the growth and find it to consist histologically of cells, fibrous tissue, and granular debris. The cells are such as found in embryonal connective tissue, and appear to be more especially confined to the peripheral portion of the tumor. The fibrous tissue is of the ordinary kind, consisting of delicate fibrils and cells. The granular debris is apparently a metamorphosis of the cells and fibres. I was unable to see any vascular structures. These histological characters, in connection with the macroscopical appearances and clinical history of the case, would lead one to consider the new formation as syphilitic in nature, a gumma."

FIG. 3.

The conditions presented by this patient when he came to the hospital and his history at once suggested that the cerebral symptoms were due to emboli. The distinct murmur heard at the apex of the heart together with the signs of hypertrophy and the general symptoms pointing toward rapidly increasing heart failure were abundantly sufficient to warrant the belief that a fragment of a vegetation had been washed from the left side of the heart into some one of the cranial blood-vessels. It struck me also that the origin of the heart disease might be syphilitic. To this suspicion I was led by the history, and because only the year before I had seen a case with a somewhat analogous condition which I reported to the College.<sup>1</sup> The two cases, although in some respects parallel, presented points of marked difference, both in the symptoms presented, in the histories, and in the different modes of death. In the first case there could be obtained no history of syphilis, either initial lesion or second-

aries, but the man had been out of health for two years; there was, however, advanced disease of the kidneys, and uræmic convulsion had occurred; the man finally died with a very slow pulse, and in a certain sense rather suddenly. In the case reported to-night, the history of chancre occurring a year before death was clear; but, as in the first case, no secondary signs had appeared, the man thought himself well until about four months before his death, which was at last caused by the cerebral embolus, and he died with the usual rapid and irregular pulse of mitral disease.

## RECENT PROGRESS IN OPHTHALMOLOGY.

By O. F. WADSWORTH, M.D.

### WHITE EYELASHES AFTER SYMPATHETIC OPHTHALMITIS.

NETTLESHIP<sup>1</sup> reports the case of a woman, aged twenty-three, who ruptured the right eye by a fall; it was excised three months later. The other eye suffered severe subacute irido-choroiditis, ending in softening and almost complete blindness; all the lashes of both its lids became white. The lashes of the first eye remained unaltered. The exact date of onset, in relation to the excision of the other eye, could not be determined. Mr. Hutchinson had described a case in which both eyes were lost by spontaneous irido-choroiditis, and many of the lashes became white. Such cases favored the theory, of late somewhat discredited, that the fifth nerve, or at least the ciliary nerves, formed the channel of communication of sympathetic inflammation from one eye to the other.

Similar cases have been previously reported, but they seem to be extremely rare. Schenkel<sup>2</sup> observed whitening of the lashes of both eyes. A boy of nine years had his left eye burst by a stone. Four weeks later sympathetic inflammation of the other eye led to enucleation of the wounded one. Three weeks afterward he was lost sight of for a time, and on his return there was found a bundle of five or six well-developed silver-white lashes in the right upper lid, while nearly all the lashes of the upper lid of the left (injured) eye were white. The color of the lashes of the lower lids and of the brows was unchanged, but there were a few scattered gray hairs on the head.

Jacobson<sup>3</sup> also has reported a case. A bit of metal entered the left eye of a man of twenty-nine years; within four weeks sympathetic inflammation of the right eye and enucleation of the left. The inflammation progressed for three months, then, after a time, the eye gradually improved. It was only several months after improvement had set in that the change in the lashes was observed. While the hair generally was quite black, the lashes of the nasal half of the right upper lid were snow white; there were a few scattered, white lashes on the outer half of this lid and on the right lower lid. For some months, at least, the condition did not change. Jacobson too suggested that the blanching

<sup>1</sup> Transactions of the College of Physicians of Philadelphia, 3d series, vol. v., 1881.

might give a hint of the method of production of sympathetic disease.

#### ON THE FREQUENCY AND HEREDITARY TRANSMISSION OF DISEASES OF THE TEAR-PASSAGES.

Nieden,<sup>1</sup> as the result of observations on the coincidence of obstructive affections of the lachrymal passage in parents and children, concludes that inheritance plays a not unimportant part in the production of these disturbances. In his practice such diseases constituted 3.6 per cent. of all diseases of the eye. This is a somewhat larger proportion than that generally given, and was presumably due to the irritating dust in the air of the district, a coal and iron region, in which he lived. During two and a half years he observed, in ninety-five individuals, nine per cent. of all the cases of lachrymal diseases, a coincidence of the same affection in parent and child; forty-six times parent and one child, three times parent and two children. In agreement with other authors he found the female sex very much the more frequently affected, and the greater predisposition of females was further indicated by the fact that bilateral obstruction occurred twice as often in women as in men.

Of the cases in which parent and child were both affected the disease was bilateral in fifty-eight per cent., while the proportion of bilateral to the total number of cases, both in Nieden's practice and that of others, was very much smaller. This fact, as well as the circumstance that, in twenty-six instances, the disease of both parent and child was bilateral, in eighteen on the same side, and in only two instances on opposite sides, points to the hereditary transmission of some malformation of the bones which form the walls of the nasal duct.

A contrary supposition, that is, that the inheritance of a serofulous diathesis was the cause, through ulceration of the nasal mucous membrane, ozæna, etc., of secondary disease of the lachrymal passages, was specially considered. No evidence to support it was found, however. Although ten per cent. of the adults affected had chronic disease of the nasal mucous membrane, not one per cent. of their children, with like obstruction of the tear-passage, had like disease of the mucous membrane of the nose. Nieden believes it more probable that long-continued obstruction of the duct excites secondarily disease of the Schneiderian membrane than that the sequence occurs in the reversed order.

#### ON THE METHODS TO HASTEN THE RIPENING OF CATARACT.

Gallenga<sup>2</sup> gives the conclusions drawn from operations in Reymond's clinic undertaken to mature partially formed cataracts. Puncture of the capsule was done twenty times, and Förster's trituration of the lens combined with iridectomy twenty-five times. Both methods answer their purpose; but incision of the capsule is naturally the simpler, and causes the cataract to mature more rapidly; generally extraction may be performed on the fifth day after the incision. Not always is it necessary to wait so long as two months after

Förster's operation. Trituration of the cortex is to be performed for immature senile cataract with hard nucleus, or when the patient cannot be kept under constant observation. For posterior polar cataract, and perhaps also for lamellar cataract, Förster's method is not efficient, but in these cases incision of the capsule is useful.

#### ÆTIOLOGY OF OPTIC NERVE ATROPHY.

Uthoff in the Berlin Society for Psychology and Neurology gave the results of his investigation of 154 cases.<sup>3</sup> Of these there were of spinal origin thirty per cent.; of cerebral origin, twenty-four per cent.; genuine progressive atrophy, fifteen per cent.; the result of neuritis, twelve per cent.; caused by orbital affections, six per cent.; in paralytic dementia, 4.2 per cent. The remainder was made up of cases of misuse of alcohol and other diseases. The high percentage (thirty) of cases of spinal origin is here noticeable, particularly in comparison with the fifteen per cent. of cases of genuine progressive atrophy. Formerly many more cases relatively were ascribed to the latter variety. Uthoff believes that the constant improvement in means of diagnosis will gradually lessen the number of cases of genuine atrophy, perhaps abolish this form altogether. Already the spinal cases are much better understood.

Four forms of defect of the field of vision are distinguished. (1) Proportionate decrease of vision over the whole field—the most common form. (2) Loss of sight in a sharply defined portion of the field. (3) Loss of the upper or lower half of the field; but the hemianopia, the symmetry, is here never exact, and such cases are to be distinguished from true hemianopia. (4) Defect of the periphery of the field with more or less intact central vision. This form was found four times. Uthoff was unable to find in atrophy a preponderance either of the nasal side (v. Graefe) or of the temporal (Förster).

Among all his cases of spinal atrophy, in only five was there coincident paralysis of the ocular muscles.

About half of the cases of cerebral origin showed traces of neuritis. A third of these patients were youthful.

Atrophy as a sequel of neuritis occurred especially in the young, and more frequently in the male sex.

Hereditary neuritis also affects males so much more frequently,—especially between the ages of twelve and thirty,—that the female sex may almost be considered exempt.

It is perhaps remarkable that the proportion of cases of paralytic dementia (4.2 per cent.) was so small, but the material was taken from the eye-clinic, not from insane asylums.

#### ACUTE OPTIC NEURITIS ASSOCIATED WITH ACUTE MYELITIS.

At a meeting of the Ophthalmological Society of the United Kingdom, Dr. Sharkey<sup>4</sup> read a paper on this subject. A girl, aged seventeen, came under the care of Mr. Streetfield on November 23,

<sup>1</sup> Centralbl. f. pract. Augenheilk., vii. 301.

<sup>2</sup> Giornale della R. Accademia di Med. di Torino, 1883. Centralbl. f. Augenheilk., vii. 447.

<sup>3</sup> Centralbl. f. Augenheilk., February, 1884. Neurol. Centralbl. 1884, No. 3.

<sup>4</sup> Ophthalmic Review, vol. iii, p. 222.

1873, suffering from severe double optic neuritis, with complete loss of vision. There was nothing noteworthy in the history, and no ground for suspecting syphilis. Vision began to fail, without evident cause, on November 9, and was quite lost by November 13. She had neither headache, sickness, paralysis, nor fits. Thirty-three days after vision failed, paralysis began, with loss of sensation, first in the left leg, then in the right. Anæsthesia gradually spread up the trunk and involved the arms, and there was incontinence of the evacuations. During the latter part of her illness she was under Dr. Bristowe's care in St. Thomas's Hospital. Cystitis came on, the temperature reached 105°, and she died of peritonitis sixty-two days after vision first failed, and twenty-nine days after the first appearance of paralysis. At the necropsy, peritonitis, cystitis, and suppurative nephritis were found. To the naked eye the brain and its membranes, and the cerebral sinuses, appeared healthy, but there were softening and great congestion of the cervical region of the spinal cord over a space two or three inches in length. The rest of the spinal cord and its membranes seemed healthy. Microscopic examination revealed the presence of acute inflammation in the softened cervical region, in the columns of Goll above it, and in the lumbar enlargement, as well as in the optic nerves, disks, chiasma, and tracts. There was slight inflammation of the meninges about the chiasma, and on the under surface of the frontal lobes. The interest of the case lay in the association of acute optic neuritis with acute inflammation of the spinal cord. It had long been known that slight changes occasionally occurred in the fundus of the eye in cases of injury to the spinal column and cord, but it was only recently that acute optic neuritis had been noted with myelitis independently of injury. Gowers and Dreschfeld had arrived at the conclusion that the optic neuritis and the myelitis were associated phenomena due to a common cause, but that neither depended directly on the other: the case detailed supported this view, for the optic neuritis preceded the myelitis by a month, and there was no evidence at the post-mortem examination of any anatomical connection. Clinically such cases were of great importance, as they simulated disease of the brain; and their occurrence, however rare, detracted somewhat from the significance of acute optic neuritis as a sign of intracranial disease.

A case reported by Chisholm<sup>1</sup> was probably of the same character, although there was no autopsy, and is of interest on account of the rapid progress of the disease. In that case also the ocular symptoms were the earliest.

A healthy man, twenty-eight years of age, arose one morning to find movements of the left eye painful; soon the sight of the eye became dim, and by night it was blind. The next morning movements of the right eye also were painful, and twenty-four hours more he was totally blind. He traveled three hundred miles by steamboat to Baltimore, arriving on the fourth day from the beginning of his ocular trouble. Except the discomfort from movement of the eyes there was no pain anywhere. There was unsteadiness of gait, first observed on

the steamboat, and then attributed to his blindness. He was unable to pass his urine, and it was drawn by catheter. The pupils were large, and there were choked disks with woolly outlines. The following day sensation was lost in the feet, and the day after the loss of sensation had extended to the hips. Temperature was 101°, as it was two days before; pulse 120; respiration normal. The loss of sensation extended steadily upward, and on the eleventh day from the first symptoms reached to a line two inches above the nipples. The sphincter and became paralyzed; the respiration shallow and finally diaphragmatic; the temperature fell to 98°. He died comatose on the twelfth day. There had been no pain, and his mind had remained clear till within a few hours of his death.

#### CONTRACTION OF THE FIELD OF VISION IN EPILEPSY.

The anæsthesia which manifests itself as a concentric contraction of the visual field, and which is frequently associated with disturbance of the cutaneous sensibility and of the special senses, has hitherto been regarded as almost characteristic of hysteria. Thomsen<sup>2</sup> made a systematic perimetric examination of twenty-eight male and fifty-one female patients in the department for the insane and epileptic in the Charité, and discovered that sensory anæsthesia occurs not alone in hysterical patients, but also in epileptics, and in a connection with the epileptic attack which, under certain conditions, may be regarded as the rule.

When the attack is a purely motor convulsion, that is, when no disturbance of consciousness or emotional disorder is combined with it, the field of vision is not contracted, but has the same normal extent after the attack as before.

On the other hand, concentric contraction of the visual field, either with or without disturbance of cutaneous sensibility, of the functions of the other special senses (hearing, smell, taste), and of the muscle sense, is found after, or with, the following conditions:—

(1) After an epileptic attack when delirium with hallucinations follows it;

(2) After post-epileptic mental bewilderment, stupor, so-called epileptic mania, etc.;

(3) After almost all similar conditions, with or without disturbance of consciousness (attacks of dread and oppression, sudden waking at night with spasmodic sensations, wetting the bed, so-called motory or sensitive aura, etc.);

(4) With more lasting post- or inter-paroxysmal conditions, which leave consciousness intact, but are attended by emotional depression and excitability. The patients are dejected in spirit, their psychological balance is unstable, they complain of all sorts of nervous sensations (palpitation, trembling, flushes of heat, ringing in the ears, dimming before the eyes, persistent headache, and sleeplessness).

All these conditions produce narrowing of the visual field; with their disappearance it again enlarges gradually or rapidly (it may be in twenty-four hours) to its normal dimensions. The contraction of the field is always concentric, never hemianopic, but is often much more pronounced on

<sup>1</sup> Archives of Ophthalmology, XI, p. 232.

<sup>2</sup> Berliner klin. Wochenschrift, 1884, No. 24.

one side. The concentric contraction is associated generally, but not always, with diminished acuteness of sight.

The cause of the epileptic attacks, which are attended by contraction of the field, is, in all probability, to be sought in a disturbance of the circulation of the cerebral cortex, which only gradually passes off, while, with the pure motor attack, the disturbance disappears immediately. That the cortex is the part affected is shown by the constant implication of the psychical functions.

### Reports of Societies.

#### BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M.D., SECRETARY.

JANUARY 12, 1885. DR. FRANCIS MINOT in the chair.

#### RAISED CIRCULAR PATCHES ON THE PALMAR SURFACE OF OVER TWO YEARS' DURATION.

DR. F. B. GREENOUGH showed the patient and said that the case was interesting in connection with two extraordinary ones recently reported. There had been a little growth which came after a slight cut received in handling glass, and which the patient had picked out for herself. In the course of a few months other growths had appeared, all being now of over two years' duration. They had appeared to consist of hypertrophied papillae. With the exception of a growth on the vocal cords, seemingly of the same nature, there had been no eruption elsewhere. Simple emollients had softened the growth a little. Afterward he had applied mercurial ointment and white precipitate, causing a red areola around it. For this reason he had stopped mercury and has since used oxide of zinc ointment. The patient had been under the care of Dr. DeBlois, who had sent her to him for the skin trouble.

DR. T. A. DEBLOIS, present by invitation, said that she came to him at the City Hospital four months ago for hoarseness, which prevented her getting her living in a store, she having been treated a year for bronchitis by a homoeopath. There were then two nodules, consisting of papillomata, on the left vocal cord. He had been trying to train the larynx, which was very hyperæsthetic, so that it would admit the use of instruments. Meantime the growth, which has always been sessile, has spread over the left cord. There has been no treatment except cod-liver oil. A four per cent. solution of cocaine has been used with absolutely no effect, and he intends applying a twenty per cent. solution and seeing what can then be done.

DR. GREENOUGH said that after Dr. Hyde's book he would consider it a case of lupus erythematosus, but that he finds it hard to conceive of a lupus erythematosus lasting three years without spreading. There are no large follicles. The growth on the forefinger looks much like a wart. Of course these growths can be destroyed with a glacial acetic acid, but would they not return? Meanwhile the efflorescence has diminished, and he is not inclined to use extreme measures.

DR. J. C. WHITE said that he had seen a few cases like it. He considered it lupus erythematosus and should not expect it to result in epithelioma. It is an obstinate disease, and while he would treat it with a saturated solution of chrysarobin in liquor gutta-perchæ, yet he thought that Dr. Greenough would have the opportunity to try many treatments.

DR. GREENOUGH. "Is it not unusual for lupus erythematosus to keep stationary for that time?"

DR. WHITE had had a case lasting five years without growth, this being verified by measure.

DR. J. J. PUTNAM showed some microscopic sections from a case of a very rare disease:

#### DEGENERATIVE ATAXIA OF THE SPINE.

These cases, of which forty or fifty have been reported, occur in groups among members of the same family. This particular group has been under the care of Dr. W. E. Smith, of Framingham, and included ten children, of whom eight were girls.

Although the parents were at first said to be healthy, rugged people, yet careful inquiry proved the reverse to be true. One member of the family had been in jail, and there has been one case of insanity. The grandfather is said, by the local antiquary, to have been a great drunkard, and the mother has a violent temper.

The pathological anatomy is somewhat like that of locomotor ataxia, although the changes occupy the whole cord instead of merely the posterior columns. The mosaic work of the axis cylinder is almost wanting.

While the most marked symptoms are those of locomotor ataxia, yet the disease is on the whole of a different type.

#### LEPRA.

DR. H. W. WILLIAMS showed plates representing a case of lepra exhibited at the meeting of the Heidelberg Ophthalmologische Gesellschaft, in September last; where, in addition to extraordinary alterations of the skin of the face, very peculiar transformation of the corneas and irides had taken place from development of the disease in those tissues.

#### COCAINE.

DR. WILLIAMS also gave an ocular demonstration of the complete insensibility produced by cocaine. Two drops of a four per cent. solution were applied to the conjunctiva, and three minutes afterward the cornea was freely touched with the finger, or a pencil or probe, the lids held open by a spring speculum, and a fixation forceps fastened upon the eyeball, without causing the slightest sensation of pain or even consciousness.

#### RAPID COURSE OF SYPHILIS.<sup>1</sup>

DR. J. J. PUTNAM said that he had referred to his notes of the case reported by him at the last meeting, and found that the gentleman, who was trustworthy and who, moreover, had no motive for deception, had had but one previous connection, two years ago, since which he had been perfectly well up to the twenty-fifth of August, when he had connection with a common prostitute. The date was

<sup>1</sup> See Boston Med. and Surg. Journal, vol. cxli., No. 1, p. 31.

fixed by peculiar circumstances attending it. At the end of the first week of September he had a sore on the foreskin at the base of the glans, resembling an abrasion of the epidermis. This grew larger. There was no moisture except once when a scab was pulled off, showing a moderate collection of thin fluid under it. Two weeks after the sore, a hubo made its appearance. This was never either tender or red. By the thirteenth of November the chancre was practically healed, as large as the nail and with slight induration. At the end of December there was a strong, reddish-blue stain with the centre a little depressed, and more marked induration.

The symptoms were malaise, sore throat coming on in four weeks after infection, and from one to two weeks after the sore, fever, and pains in the back and limbs, enlarged tonsils in six weeks from infection, ulcerated tonsils in eight weeks from infection, iritis in two months. Cutaneous symptoms were observed November 13, in the shape of scattered, dull-red papules, a few of them on the face, and thick scales. Gradually more papules developed. They are now nearly gone except upon the back. There were patches on the tongue for some weeks, and the strength was much reduced. In the third week of November, ten or eleven weeks from the sore, thirteen or fourteen weeks from infection, two symmetrical tumors were observed over the flexor carpi ulnaris near the elbow, one on each arm under the skin, and somewhat adherent to it, but not at all to the fascia; as large as almonds, and but little red or tender. Similar tumors were found at the muscular attachments of the tendo Achillis.

The speaker had quoted Mauriac. The symptoms reported by him as organic hemiplegia appeared in three months. Cooper, in a recent English writing, quotes from Fournier a case of cerebral gumma in three months, but does not say whether there was an autopsy. Ziemssen speaks of a deep-seated violent ulcer of the penis in December, and disease in August, which he says might be called gummata, but he does not so call it.

Dr. GREENOUGH said that this case is so fully reported that it does not strike him as strongly as it did before. There can be no question as to the disease or as to the date of infection. The question is, Were the later symptoms, three months after infection, tertiary? If there is any disease which is regular in its course within certain limits it is syphilis; and the occurrence of gummata in so short a time was as strange to him as a fractured spine without paralysis would be to Dr. Putnam. Kollet reports a case in which secondary symptoms came on in twelve days from a chancre. This is the shortest period that he, Dr. Greenough, can find recorded; and he asked Dr. Putnam if he had given iodide before the occurrence of sore throat.

Dr. PUTNAM answered that he gave no iodide until ten days after the occurrence of sore throat.

Dr. GREENOUGH continued, that while cerebral symptoms appear to occur more commonly than in former times; at least are more often reported; and while they sometimes occur quite early as in the case reported by Dr. Homans at the last meeting, when they came on in six months, and as happened in four cases of his own; yet that he

believes that they are the result of inflammatory processes in the brain, that is, that they are secondary; and are not due to gummata, which last are not inflammatory products but neoplasms, that is, are tertiary. He doubts if it is possible for gummata to occur so early.

Iodide has sometimes a marked effect on the skin. He quoted Hutchinson that iodide in fifteen-grain doses three times a day has so destroyed the skin as to cause death; and he had himself been told by druggists that it was often adulterated with bromide of potassium. He had never seen a gumma of the skin that did not begin without inflammation as a bunch under or in the skin like a lipoma, but not so soft and not lobulated. It may become inflamed and red, and may break down, leaving an ulceration.

Dr. PUTNAM said that the tumors in question could not be better described than by Dr. Greenough's description of gummata, and that they had disappeared while iodide was being taken.

Dr. GREENOUGH inquired why they may not have been large glands.

Dr. PUTNAM answered that they were over the elbow and the lower calf.

Dr. WHITE being called on by the chairman said that he had nothing to add to what he had said at the last meeting.

THE PRESIDENT, Dr. F. W. DRAPER, in the chair.

Dr. W. L. RICHARDSON read a paper on

#### A CASE OF ABDOMINAL TUMOR.<sup>1</sup>

Dr. W. W. GANNETT reported the autopsy which is published with the paper.

Dr. JOHN HOMANS said that he had seen the abscess opened by his brother, and that it gave relief. The patient died, as do all cases of chronic abdominal abscess, the bottom of which cannot be reached by the surgeon.

Dr. RICHARDSON said that the improvement was so great that he had thought there might be a mistake as to diagnosis. It did seem as if the trouble might be caused by dead bone, resulting from the accident.

#### PATHOLOGICAL SOCIETY OF PHILA-DELPHIA.<sup>2</sup>

Dr. SHAKESPEARE said that he had read of two attempts within the last year or two to isolate the micrococcus of this disease. Bruylants and Ferrier united in an attempt of this kind and have reported their observations in the *Bulletin de l'Académie belge* (1880), to the effect that they found a micrococcus constant in the pleuritic and alveolar exudate. More recently the report of Poels and Nolen, of Rotterdam, has appeared, in which they describe the isolation and culture of many generations of micrococci. Moreover, they have compared them with those of human pneumonia, claiming their identity morphologically and with regard to their mode of growth; and a further identity as to the results of inoculation, their experiments

<sup>1</sup> See page 76 of this number of the JOURNAL.

<sup>2</sup> Concluded from page 611, vol. cx1.

showing that pleuro-pneumonia in cattle has been produced by inoculation of the cultures of micrococci from human crupous pneumonia as well as by inoculations of cultures from the pleuro-pneumonia of cattle. The latter report is published in the *Centralblatt für die medicinischen Wissenschaften*, No. 9, 1884.

Dr. FORMAD said that this micro-organism had also been seen and described by Veterinary Surgeon Lyman, who had presented a very elaborate report to the Department of Agriculture. Dr. Linle also, both a medical man and a veterinary surgeon, had worked in pleuro-pneumonia for two years in the Pathological Laboratory of the University of Pennsylvania, always finding the micrococcus present, and in pure cultures kept up for many generations he had not observed any other bacteria. He had inoculated two calves with large quantities of the culture and had failed, whence he had concluded that the micrococcus was not the cause of the disease.

Dr. DEXS in his concluding remarks said that one point of interest had been omitted in his paper, which was, that the cattle from which the specimens had been obtained had been first knocked down, then bled to death, and buried *superficially* in a field through which flowed a stream from which neighboring herds were watered. In a few weeks the disease appeared in these cattle also. As to the literature of the subject, he had not access to sufficient to familiarize himself with any investigations made by others. Some experiments with reference to inoculation have been successfully made in France and England. The lymph was introduced into the body and tail, and was found to protect the animal from the disease. When the virus was inserted into the tail with proper precautions the mortality from the operation was less, being from one to two per cent. It was also found that when the tail became greatly inflamed it could be removed to limit the inflammation and still afford protection to the animal. Inoculated animals did not communicate the disease.

#### A CASE OF UNUNITED FRACTURE OF BOTH BONES OF THE FOREARM.

Presented by CHARLES MEigs WILSON, M.D.

Eight months previously the patient fell from a window and sustained an oblique fracture of the ulna and radius; that of the ulna being about an inch and a half and that of the radius two inches and a half below the elbow-joint. The specimen shows that there has been no attempt at union in the radius; but that the comminuted fragments being attached to periosteum have not been destroyed. There has been slight union of the ulna. The cartilages have been destroyed. The joint contained pus, and the internal condyle of the humerus showed a carious condition. The patient made an excellent recovery after amputation.

#### CASE OF MULTIPLE OVARIAN CYSTOCELES WITH SUBPERITONEAL FIBROIDS AND GENERAL (TUBERCULAR) PERITONITIS.

Presented by Dr. H. M. FISHER.

Barbara K., aged forty, married, born in Germany, was admitted to the Episcopal Hospital early in July. Her father died of a tumor in the axillary

region, one sister of paraplegia, at the age of sixteen, and one brother and one sister are still alive and healthy. She married early and had three children. Of these one lived but one day, one died at the age of twelve of "dropsy," and the third (a boy of eighteen) is still living. Two weeks after the birth of the last child she was obliged to get up and make severe muscular exertion, actually laboring in the fields. Soon after this she noticed that she was losing blood *per vaginam*, and that she could no longer nurse her child. This bleeding appears to have recurred at intervals of ten weeks for a year or more, and often amounted to a positive hemorrhage. Notwithstanding that this was the case and that she had occasional attacks of severe pain, she continued to work as usual until three or four years ago. At about this time she noticed a lump in her left groin, and from this time her abdomen steadily increased in size; she was seldom entirely free from pain, her appetite failed, and her bowels were habitually constipated.

*Status Præsens.* Patient is anæmic and has a careworn, haggard look. Abdomen much distended. Distance from xiphoid to umbilicus two inches greater than from umbilicus to symphysis. Percussion clear over abdomen anteriorly, dull in flanks, and fluid moves freely with patient's movements. Hepatic dulness begins in third interspace in mammary line, but not apparently increased in width. Examination of heart reveals a faint systolic apex murmur; examination of lungs gives negative result. Much dyspnoea. The dyspnoea becoming urgent she was (July 14th) tapped in the median line, two inches below umbilicus, and eight quarts twelve ounces of a straw-colored fluid rich in albumen were removed. Immediately after the tapping an exceedingly hard mass was noticed in the left iliac region apparently of the size of a turkey's egg. On the 23d she complained of much pain in the left leg, and the tissues were noticed to be œdematous.

From this time till her death patient complained much of dyspnoea, hypogastric pain, and obstinate constipation. She was tapped twice again, and on each occasion a large amount of straw-colored fluid was removed. On September 21st she had an attack of dyspnoea, and died in ten minutes.

The resident physician, Dr. J. K. Mitchell, furnished the following notes of the autopsy:—

— Drew off fourteen quarts of fluid from the abdominal cavity by trocars and canula, all clear and straw-colored. On reinserting canula a small quantity of dark-brown fluid, looking like beef-tea, came through. The belly-walls were very thin; peritoneum everywhere much inflamed; whole intestinal surfaces and peritoneum covered closely with small whitish or pinkish points of tubercle; glands not very much enlarged, but very hard; omentum as thick as one's hand, and of an almost wooden hardness and stiffness. Liver and kidneys apparently perfectly healthy. Two cysts in the broad ligaments of the uterus, one a little smaller than a baseball, the other still smaller. One had been tapped by the canula, the other contained about four ounces of the same brown 'ovarian' fluid. The ovaries macroscopically seemed healthy, and the uterus was normal in size and position."

A subsequent examination of the specimens brought the following facts to light: The uterus is decidedly hypertrophied, extending about four inches internally, and appears abnormally hard. Closely attached by false membranes to the lower part of the body of the uterus upon the right side there is a *hard fibrous nodule* of the size of a pigeon's egg. A somewhat larger mass of similar character is seen higher up and to the left of the uterus. The right ovary is enveloped in false membranes and closely adherent to the fundus of the uterus. The left Fallopian tube opens directly into the larger cyst of which mention has above been made. This has at its base a fibrous nodule (about two and one-half and three-fourths inches) which is covered on its under surface by a mass of false membrane. (This is probably the mass that was detected during life in the left inguinal fossa.)

In addition to the cyst above mentioned there were two other smaller cysts, but it was found impossible to make out the exact relations of these to the other cysts. None of these cysts appeared, however, to be connected with either broad ligament. The left broad ligament was found to be perfectly free, the right was wanting, but appeared to have been removed during the autopsy or subsequently.

The case is a complicated one, but the sequence of pathological events appears to have been the following: The patient having made severe muscular exertion a fortnight after confinement is attacked by perimetritis and metritis. This inflammation, soon becomes chronic in consequence of the want of proper care and rest. Whether the subperitoneal fibroids had already developed at the time this acute pelvic inflammation occurred, it is now impossible to say, but it is probable that they were of later development. Coincident with the periodical hemorrhages and attacks of pain that the patient now suffers from, fresh portions of the pelvic peritoneum are invaded. Finally, the peritoneum adjacent to the ovary is reached and a periöophoritis is the result. The inflammation of the peritoneal investment of the ovary extends, as Heitzmann states, to the ovary itself, causing a proliferation of connective tissue in the cortex of the organ and from here to the adjacent connective-tissue stroma. In this way the bursting of a ripened follicle may, as he says, be prevented, and a path may be opened for the formation of an ovarian cyst. Supposing this to have occurred in this particular case, we may easily see how the connective-tissue proliferation may have gone on hand in hand, as it were, with the cystic degeneration of the ovary until the whole ovary was converted into the multiple fibro-cyst that we see in the specimens.

The inflammation extended but slowly from the pelvic to the general peritoneum, probably because the products of inflammation were for a long time in great measure circumscribed by false membranes. Little by little, however, these products were taken up by the lymph channels until finally the whole peritoneal surface was infected by them. The occurrence of general peritonitis probably did not antedate much the occurrence of the abdominal dropsy, three years ago.

## Medical and Surgical Journal.

THURSDAY, JANUARY 22, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by CUPPLES, UPHAM & CO., Boston. Price, 15 cents a number; \$5.00 a year, including postage.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUPPLES, UPHAM AND COMPANY,  
289 WASHINGTON STREET, BOSTON, MASS.

### THE GOVERNOR OF MASSACHUSETTS UPON THE STATE'S MEDICAL EXAMINERS.

THE late annual message of the Governor of Massachusetts, in marked contrast to that of his erratic predecessor, Governor Butler, was a very staid and, one might almost say, tame state paper. In fact, it appears as though his excellency had shrunk from touching anything approaching the character of a burning question. The medical fraternity certainly searched the document through in vain for any allusion to the working of the present conglomerate Board of Health, Lunacy, and Charity, for any suggestion as to change or modification in its organization; nothing is said of the consolidation of the departments of indoor and outdoor poor, or of its results, though we believe it might have been stated that these are so far entirely satisfactory, both from the negative point of view of what has been dropped and from the positive, but scarcely more desirable, one of what has been gained.

One genuine sensation, however, this message contains, which immediately attracts the eye of the reader in search of what was omitted in regard to the other and more important questions of "State Medicine." We refer to the long paragraph devoted to medical examiners. This in some respects quite takes us back to some of the efforts of ex-Governor Butler, and it really seems as if one erring medical examiner had been offered up as a sacrifice for the sins of the whole Commonwealth.

It appears from the Governor's message that one medical examiner, whose conduct we do not for an instant desire to justify or defend, increased his fee on one occasion—and there is an implication that the instance was not a solitary one—from four dollars to thirty, by holding an autopsy upon a body mutilated by a railway train, when it was very plain that a simple view would have been quite sufficient to determine the cause of death.

This instance is cited as illustrating a possible abuse of their office by the medical examiners of the State under the law as it now exists, and the recom-

commendation is made that in future they be required to report all autopsies to the district attorneys, and make oath in each case that in their judgment the cause and manner of death could not be ascertained by view and inquiry, and that an autopsy was fairly necessary for that purpose; that it be made the duty of district attorneys to examine such reports, and to certify to the county commissioners whether, in their opinion, such autopsy was required; and that no fee for an autopsy be paid without the approval of the district attorney so expressed. Further, let medical examiners make reports at definite periods of all cases investigated by them, to the State Board of Health, Lunacy, and Charity, upon blanks to be furnished by the Secretary of the Commonwealth for that purpose.

"It is probable that the need of other amendments defining certain wards and clauses, fixing the rate of fees, and otherwise making clear the intent of the statute, will be presented for your consideration."

This much of what his excellency thought it incumbent upon his office to say as to the system of medical examiners in his State is proper and suitable enough, though one cannot concur in the wisdom of his first recommendation, as we shall presently show: but what precedes it, to speak mildly, is unnecessary, sensational, and exaggerated, as well as unjust both to an excellent system which is regarded as a model by other states and countries, and to an exceptionally honorable and expert body of professional men, who may have little political influence, but who, with a very rare exception, have proved honest and capable servants of the State.

The statute providing for the appointment of medical examiners, after being in operation seven years, his excellency is pleased to admit "has on the whole proved satisfactory." So much for commendation. But, "instances have come to my knowledge in which the examiner has held an autopsy over the body of a person killed instantly by a railroad accident, in broad daylight, in the presence of several spectators, the body being literally torn into fragments. As an illustration of objectionable practice in such a case, I give a medical examiner's report of an autopsy conducted by him:—

"Autopsy:—Found head and left arm severed from body; right arm broken at wrist-joint, and right leg and foot badly broken and mangled."

"It ought not to be possible for an officer to practice such abuse of official power, and the district attorneys, mayors, and selectmen should be held to greater vigilance in the exercise of their authority, which alone enables the examiner to so proceed. As it is now, with the exception of the officers paid a fixed salary, the examiner needs only to hold an autopsy in every case to increase his fee from \$1 to \$30, and the county or state treasury must respond. It must not be understood that all, or even a major-

ity of medical examiners in commission, put so lax a construction upon the statute authority; but the opportunity for unprofessional conduct endangers the public interests, and tends to bring into disrepute all these officers, to whom are intrusted so great responsibilities. Large discretion must be given in the interests of public safety and justice, but an efficient restraint in this regard is demanded."

A perusal of this certainly leaves the impression upon the mind of the readers that, although a majority of the medical examiners are conscientious, a very considerable minority are addicted to the vicious practice of robbing the State of \$26 whenever a suitable opportunity presents itself—an opportunity which, in the experience of many of them, must be rare.

Now, there are certain comments upon this which we should be false to our duty to the public and the profession if we failed to make.

In June last the Governor reappointed nearly the entire corps of medical examiners after a public challenge for charges against them. In January his message contains charges against these same men. Had he stated the *number* of instances of such abuse as he charges, we have reason to believe the public would have been astonished at the slender thread upon which these sensational paragraphs of his message are strung. When found out, as in the case cited, the remedy for such abuse is to *cancel the commission*, as the statute already provides. Instead of this radical, simple, and curative measure, the Governor proposes to bring all under the yoke in order that the few may be kept in subjection. The proposal to make district attorneys censors to whom a sworn affidavit should be sent as to the necessity for each individual autopsy would be a needless bother to good men, who already spend disproportionate time and labor upon the careful, conscientious study of doubtful cases, and would be useless as a restraint for bad men. The oath of office covers the whole subject, and a man who violates one oath will not be checked by two. Care in appointing as medical examiners men of good personal and professional reputation, and prompt revocation of commissions when found unworthy, are amply sufficient to control abuses, "instances" of which, on the part of the minority (*sic*) of the examiners, have come to the Governor's knowledge.

The suggestion that medical examiners should be required to report their work to some central authority has much more to commend it as a useful measure. It is, we know, desired by the medical examiners themselves. It, too, would tend to check any abuse of which the Governor complains, as we feel sure overmuch, by letting daylight in upon official work, for malfeasance is impossible when open to exposure. Such a compulsory report would have the additional advantage of affording an opportunity for collecting a great number of facts each year concerning deaths by violence—facts which are now

but partially secured through the agency of the Medico-Legal Society, and which must be of the highest value in legal medicine if properly arranged and presented.

That the present Board of Health, Lunacy, and Charity would be a proper body to receive and consider such reports, any one having knowledge of the composition of that board, and of the details of the work of the medical examiners, would be somewhat loath to admit.

It is gratifying to see vigilance exhibited by the State Executive in regard to any of the State's business, but it is impossible to repress the reflection that had even a little of the stringency meted out to the unfortunate medical examiners been exercised in recent years toward other servants of the State, in other departments not far removed from the executive chamber, our present Governor would in all probability never have been called upon to distinguish himself in the still memorable political struggle against his predecessor.

#### THE EFFECT OF OUR SUDDEN AND REPEATED CLIMATIC CHANGES UPON CHILDREN.

THE winter of 1884-85 has thus far presented such an unusual variety of climatic changes, and the sudden rise and fall of the mercury in thermometer and barometer, with an accompanying preponderance of damp, searching weather, has been so marked, that it would be extraordinary if the younger portion of our population, with all its sensitive organization ready to be affected by unusual changes, should escape manifesting in some way phases of disease peculiar to its age and stage of development.

The various catarrhal conditions of the throat, nose, and middle ear, are taking a peculiarly prominent position, not only from their great increase in frequency, running almost like an epidemic through large families of children, but also from the uncommon symptoms which they are producing in other parts of the economy. This has, during the last two months, become so noticeable, where numbers of children have been carefully observed, that it seems as though a note of warning would not be out of place. The general practitioner should be fully alive to the difficulties which may arise regarding the diagnosis of cases where, although the general symptoms may decidedly point toward cerebral, laryngeal, thoracic, or even gastric trouble, yet they are in reality only of reflex origin, and even when symptoms of aural disease are entirely absent, yet the seat of reflex irritation may be a catarrhal condition of the middle ear, usually produced by extension from the pharynx and posterior nares.

Thus, at a season when, besides these catarrhal affections, we are witnessing an increase in acute pulmonary attacks represented by bronchitis, lobar

and broncho-pneumonia,—the latter disease often for days absolutely giving nothing distinctive of its presence by means of physical signs, but only presenting a quickened respiration, with increased action of the *ala nasi* and a heightened temperature,—it is of the greatest importance to recognize the fact, that exactly the same symptoms may be caused by inflammation of the middle ear developing slowly, without any special pain, and, in fact, no manifestation of its presence appearing until the *membrana tympani* has been perforated and the escaping discharge has carried with it the evidence by which the various symptoms can now be explained and relegated to their proper domain of reflex irritation.

The connection between the brain and middle ear, with reference to its blood-supply, is in children much more intimate, from the presence of the still pervious petro-squamosal fissure, than that which is found in later life; so that, while changes in the former can at times be indexed in the ear, congestions of the *tympanum*, by increasing the tendency to overfilling of the cerebral vessels, may thus lead to cerebral symptoms, often of a serious nature, but, again, only serious so far as the *symptoms* go, provided that these symptoms are recognized as reflex, and that the source of the reflex irritation is detected in the ear.

Thus, children have been known to lie in an unconscious condition for days, with all the appearances of cerebral disease, and yet consciousness has been entirely restored on the occurrence of perforation of the *membrana tympani* with a purulent discharge. And it is not only by early puncture of this membrane that the continuation of these reflex cerebral symptoms can often be cut short. It is in this class of cases especially that the importance is evident of the general practitioner having a sufficient knowledge of aural disease to examine the ear thoroughly, early in the course of the attack, before deeper-seated mischief has occurred, and, if need be, by the aid of the specialist to relieve at once a condition where every day's delay may produce irreparable injury.

In young children especially, subjected to the influence of a winter like the present one, it is very noticeable that catarrhal tonsillitis may occur with absolutely no local symptoms, the infant or child, perhaps, showing merely a mild constitutional disturbance, characterized by a slight rise in temperature and loss of appetite. These slight variations from health to disease are seldom thought by the parents to be of sufficient importance to require a physician at the outset of the trouble, and it is only when attending other members of the family, or when more marked symptoms arise, such as drowsiness, quickened respiration, or cough, that the medical attendant has an opportunity of examining the child.

He now finds probably very little in the throat to

account for the varied symptoms which come under his notice; the catarrhal tonsillitis has perhaps so far run its course as to afford no clue to the diagnosis, and yet the same catarrhal condition may have insidiously extended to the posterior nares and thence by the Eustachian tubes into the middle ear, resulting sooner or later in perforation. If a mucopurulent discharge has not taken place, and an examination of the ear has not been made, still further obscurity is thrown on the case; even though this catarrhal condition of the ear be manifest, yet we are now often met with an array of symptoms which are exceedingly puzzling until the possibility of their reflex origin is determined and their probable harmlessness recognized.

The nervous system of the child is so much more highly developed than that of the adult and is so exceedingly sensitive to all kinds of impressions, whether from changes without or from changes within, that it is no wonder that, with the close connection between the ear and other parts of the economy through the otic ganglion acting as a central station from which impressions can be switched off, so to speak, and carried to other organs, symptoms are produced which are not the result of disease of those organs but of their reflex irritation.

A marked instance of this phenomenon is the so-called ear cough, where children develop a laryngeal cough with nothing found to account for it in the pharynx, larynx, lung, or stomach; the cough apparently being excited by foreign bodies, causing irritation of the sensitive fibres of the auriculo-pneumogastricus distributed in the meatus and reflected along the motor fibres of the superior laryngeal nerve. In like manner there are instances where young children with inflammation of the middle ear have developed cough and dyspnea, relief from which could only be obtained by inflating the tympanum by means of the Politzer air-douche.

As a summary then of observations which have recently been made on large numbers of infants and children subjected to changes from an intensely cold dry atmosphere to a moist warm one, within a period often of a very few hours, particular attention should be given to an examination of both throat and ear—whether special symptoms point to these parts or not—on the ground that catarrhal tonsillitis may occur and run its course in young children without local symptoms, but with the liability of the catarrhal condition extending and producing serious reflex symptoms elsewhere. Also, the great importance becomes apparent of a more exact knowledge of the methods of detecting aural disease than is usually possessed by the general practitioner, to the end that not only many serious results from overlooking the aural disease may be obviated, but also that, when inflammation is evidently present, the mistake may not be made of failing to interpret certain cerebral, laryngeal, and thoracic symptoms as undoubtedly reflex and hence not in themselves

of serious import, provided that the disease of the ear can be controlled. Parents and friends of our little patients may thus too be spared untold anxiety during the period of legitimate doubt as to the prognosis.

#### A NEW MODE OF USING AN OLD REMEDY —CHLOROFORM WATER.

CHLOROFORM, an old remedy in the practice of the majority of practitioners, though doubtless a new remedy in the experience of the octogenarian, may be utilized for other purposes than anaesthesia, and the saturated chloroform water, first formularized by Guillot in 1841, and which was afterward made the subject of a series of trials by Lasègue and Regnaud,<sup>1</sup> and still more recently by Beumann,<sup>2</sup> is not only an excellent and handy excipient for many medicines, but possesses valuable analgesic properties. It is a stable preparation, and the savor is especially agreeable, sweetish, and when diluted one half, devoid of all piquancy and acidity; it makes a good combination with nearly all medicines which it is desirable to administer in a liquid menstruum, disguising the insipid or unpleasant taste of many of them; it markedly enhances the sedative and anodyne properties of analgesic and narcotic remedies. Lasègue especially recommends chloroform water as a suitable vehicle for the administration of morphia, in union with which it forms one of the best palliative cough medicines, as is generally acknowledged, in advanced phthisis.

Probably no better excipient for the salts of iron can be found. The mode of preparation is very simple. Into a flask two thirds full of pure water, pour an excess of chloroform, agitate well the mixture several times for the space of an hour, and allow the chloroform to deposit itself on the bottom of the flask. Decant or syphon off the clear supernatant liquid. The solution should be perfectly transparent, containing a little less than one per cent. of chloroform. For internal administration it is generally desirable to dilute this saturated solution with an equal quantity of water; the dose of the dilute aqua chloroformi being about a dessert-spoonful.

Lasègue has shown the unreliability of alcohol as a solvent for chloroform, and the difficulty of making a good preparation of chloroform water from the official spirit solutions. Nor are the emulsions free from a certain irritant effect and even causticity, felt for some time in the stomach after the ingestion; sometimes manifesting itself as acute pain.<sup>3</sup>

Among the therapeutic advantages of chloroform

<sup>1</sup> Archives gén. de Médecine, 1879 and 1882.

<sup>2</sup> Bulletin gén. de Thérapeutique, t. xv, p. 97.

<sup>3</sup> Lasègue, loc. cit., and Etudes Médicales, t. ii, p. 1147. Alcohol at 50 per cent. dissolves nearly twice its weight of chloroform. At 80 per cent. 1 gramme of chloroform is soluble in 1 gr. 5 of alcohol. At 60 per cent. 1 gramme requires 6 gr. 10 for its solution. At 20 per cent. 1 gramme requires 62 grammes for its solution, etc.

water is one on which Lasègue and Beurmann much insist, namely, its use as an analgesic in painful stomach affections, whether these proceed from indigestion or from organic disease. In the pains of indigestion it is almost without a rival, speedily mitigating the functional distress by its marvelous topical sedative action. In the painful intestinal disorder often accompanying the completion of digestion, it is of no utility. Beurmann has had favorable experience with its employ in allaying the acute suffering and nausea which attend dilatation of the stomach, especially during the digestion of food. He also strongly recommends it in cases of gastralgia, and here he is seconded by Dujardin-Beaumetz, who introduces the diluted chloroform water by the stomach-tube, performing "lavage" with the solution, his formula being two teaspoonfuls of saturated *aqua chloroformi* to the quart of liquid.<sup>1</sup> This preparation he regards as both caln-ative and antiseptic, and the washing process is, above all, indicated in gastric dilatation. Lasègue also finds advantage from chloroform water in the pains and nausea which accompany cancer of the stomach.

From the list of formulæ given by Beurmann we select the following:—

- |    |  |              |
|----|--|--------------|
| R  | Sat. chloroform water . . . . .  | 13 parts.    |
|    | Peppermint water . . . . .   | 3 parts.     |
|    | Water . . . . .  | 12 parts.    |
| M. | Dose, a tablespoonful for a caln-ative stomach potion. Good in nervous vomiting and the vomiting of pregnancy. |              |
| R  | Saturated chloroform water . . . . .   | 3 parts.     |
|    | Syrup of orange . . . . .  | 3 parts.     |
|    | Liquid morph. sulph. . . . .   | 1 part.      |
| M. | Dose, one or two teaspoonfuls. The above is a useful form for the administration of morphia.                   |              |
| R  | Hydrate of chloral . . . . .   | 1 part.      |
|    | Syrup aurantii cort. . . . .   | 25 parts.    |
|    | Sat. chloroform water . . . . .  | 50 parts.    |
| M. | Dose, a tablespoonful. The erid taste of chloral is much modified when administered as above.                  |              |
| R  | Sat. chloroform water, peppermint water . . . . .  | 55.50 parts. |
|    | Syrup of popples . . . . .   | 30 parts.    |
|    | Bronide of potassium . . . . .   | 1 part.      |
| M. | This preparation in teaspoonful doses is exceedingly valuable in the therapeutics of infancy.                  |              |

The following is called by Dr. Beurmann the "salicylic potion":—

- |   |                                   |            |
|---|-----------------------------------|------------|
| R | Salicylate of soda . . . . .      | 8 parts.   |
|   | Syrup . . . . .                   | 30 parts.  |
|   | Peppermint water . . . . .        | 20 parts.  |
|   | Dilute chloroform water . . . . . | 100 parts. |

The disagreeable taste of salicylate of soda is almost completely disguised in this mixture.

The following, called "hemostatic potion," contains iron:—

- |    |   |              |
|----|---|--------------|
| R  | Dilute chloroform water . . . . .   | 130 grammes. |
|    | Syrup aurantii cort. . . . .  | 20 grammes.  |
|    | Liquor ferri perchloridi . . . . .  | gii. xx.     |
| M. | Dose, a tablespoonful. The styptic taste of the ferrie chloride is almost completely removed in this combination. |              |

<sup>1</sup> Dujardin-Beaumetz, in *Therapeutic Gazette*, December, 1884, p. 531.

Lasègue recommended a now somewhat famous hydragogue cathartic potion, which is made by rubbing up one gramme of gamboge with fifty of syrup of orange and one hundred of saturated chloroform water. The dose is a tablespoonful every morning or every second morning.

The above formulæ are examples of the therapeutic range of this medicament. They can be varied at pleasure by the practitioner to meet special indications.

## MEDICAL NOTES.

—What is a patient's right in a prescription? In paying his physician's fee, has he bought and paid for his prescription? If so, he owns it. The obligation of a druggist not to refill a prescription if expressly forbidden to do so by the prescriber is probably generally recognized. But if the patient owns the prescription he has a right to make or to obtain a copy of it, and this copy presented to another druggist will procure the medicine at any time, and for any number of times. Hence, in order to prevent the refilling of a prescription which may lead to the injury of both patient and practitioner, it is necessary to resort to the somewhat arbitrary proceeding, as it certainly seems, of forbidding the druggist to give a copy of any recipe. Whether such a prohibition is likely to prevail against the druggist's interest in obliging a good customer, to say nothing of a patient's possible legal rights, is a question. The patient's endeavor to make a copy himself before taking the prescription to a druggist can only be thwarted by the physician's sending his recipe direct to the pharmacy, and instructing his patient to call there for the medicine.

—The eleventh annual meeting of the American Neurological Association will be held in New York on Wednesday, June 17, 1885, and will continue three days.

—Twenty-two appointments of assistant surgeons to the U. S. Army have been made during the past year, and there are now no vacancies in the medical corps of the army.

## PHILADELPHIA.

—The Annual Meeting of the College of Physicians was held on the 7th instant. The following officers were elected to serve the ensuing year: President, J. M. Da Costa; Vice-President, S. Weir Mitchell; Secretary, Richard A. Cleemann; Treasurer, Chas. Stewart Wurts; Honorary Librarian, J. N. Hutchinson; Recorder, J. Ewing Mears; Censors, Lewis Rodman, Edward Hartshorne, William Goodell, Alfred Scillé; Councillors, I. Minis Hays, A. V. Meigs, R. P. Harris, and the usual standing committees. A resolution was adopted appointing September, 1887, as the time

for holding the Centennial Celebration of the founding of the College; and measures were authorized having in view the enlargement of the Hall by the erection of a third floor for the purpose of providing better accommodations for the Mütter Museum, which is constantly increasing in importance and size. At this meeting Professor William Pepper read the clinical history of a case of Addison's disease with the report of the autopsy by Professor Osler. The supra-renals were enlarged, and were adherent to surrounding structures; on section they were distinctly tuberculous with points of caseation. No bacilli were discovered. The specimens were shown, and microscopic sections were also exhibited.

Dr. J. H. Musser presented an immense gallstone with a brief history of the case.

—At the annual meeting of the Philadelphia County Medical Society, Dr. R. J. Levis was elected President, and Drs. Oscar H. Allis and DeForest Willard, Vice-Presidents. The other officers were reelected.

#### NEW YORK.

—Dr. George M. Sternberg, major and surgeon, United States Army, now connected with the Johns Hopkins University, Baltimore, gave a lecture on infectious diseases in their relations to armies, at the College of the City of New York, January 8th, before the Military Service Institution, which usually holds its meetings on Governor's Island. In the course of it he remarked that unless a general consideration of the topography of a country in which he was to conduct his operations, from a sanitary, as well as a military, point of view, the best planned campaign might result in disastrous failure. In the light of modern science, the commander was held responsible for the occurrence of epidemic filth diseases in his troops, and the lecturer suggested the following general rules for their prevention: *First*, prevent the introduction of exotic germs, such as those of cholera and yellow fever. — *Quarantine.* *Second*, endeavor to destroy the germs of infectious diseases in all material which is known to contain them, such as the discharges of typhoid or cholera patients, and the sputa of those suffering from diphtheria or tuberculosis. — *Disinfection.* *Third*, dispose of all material which might serve as pabulum for the external development of these germs in such a way as to make it unavailable for their use. — *General sanitation.* On the day following Dr. Sternberg made some experiments in the disinfection of rags at Bartlett's storerooms in Brooklyn, in the presence of assistant secretary of the treasury, H. B. French, the collector and health officer of the port, and representatives of the boards of health of New York, Brooklyn, Boston, New Haven, and other cities. The apparatus used was invented by Dr. Pollock, and consisted of a box large enough to hold a good-sized bale of rags, from the back of which projected five long, revolving, augur-shaped

screws, worked by steam, by means of which the bale to be disinfected is pierced and drawn into the box; the lid being afterward tightly closed. In the first experiment a bale of rags infected with microbes furnished by Dr. Sternberg, was subjected for three minutes to the fumes of sulphurous-acid gas in the box. In the second, a similarly infected bale was subjected for fifteen minutes to a temperature of 280° F., produced by charging the box with steam; the rags being thoroughly saturated with moisture by the time the bale was withdrawn. After thoroughly testing the destruction of the vitality of the germs employed, Dr. Sternberg will make a report to the Secretary of the Treasury on the results of these experiments.

A nest of typhus fever has been discovered in a filthy tenement-house in West Twenty-third Street, near the Hudson River. The first case was that of a woman who died of the disease on the fourteenth of December, but as her death was assigned to pneumonia, the attention of the health authorities was not directed to the premises. A dozen cases were found in the house on the sixth of January, and altogether fourteen or fifteen cases have resulted from this first one, the origin of which is as yet unknown. Of these, the brother of the woman died in Brooklyn, January 5th, and there is also some ground for supposing that the priest who administered the last rites of the church to her, and who died January 4th, was also a victim of the disease, although the physician who attended him is convinced that his was a case of remittent fever. Several other cases of typhus have also been reported of late in different parts of the city.

### Correspondence.

#### ARMY ITCH.

BOSTON, January 19, 1885.

MR. EDITOR.—In reply to Dr. Wilder's comments, published in the *JOURNAL* January 15th, upon my brief remarks in relation to the unusual recurrence of scabies at the present time, and the opinion prevalent with regard to it during the War of the Rebellion, permit me to call his attention to a communication upon army itch in this journal, March 22, 1866.

Respectfully yours,  
JAMES C. WHITE, M.D.

#### THE USE OF THE ASPIRATOR.

1 Union Place, Troy, N. Y., January 9, 1885.

MR. EDITOR.—I have just received a *review* by Dr. Henry I. Bowditch, of Boston (reprinted from the *Boston Medical and Surgical Journal* of December 11, 1884), of a paper on "The use of the Aspirator in Hydrothorax," read by me at the recent meeting of the New York State Medical Association.

The *review* is based upon certain propositions ascribed to me and referred to as having appeared

in your journal of November 27, 1884, in a report of my paper, but as my paper did not contain the "propositions," and as it has not been published, the criticism is premature.

I shall allow the paper itself to stand as my answer, and it will soon be published, simply stating here that I did not seek to condemn the Aspirator, but to record a warning as to the serious and even fatal results which might be fairly ascribed to its careless use.

Your obedient servant,

E. D. FERGUSON, M.D.

In regard to our report of Dr. Ferguson's paper, we need only say that it came from a particularly reliable source, and agreed substantially with other reports. Whether it should bear the interpretation put on it, we will not undertake to say. — [Ed.]

### INCREASE IN WATER-RATES IN BOSTON.

Boston, January 12, 1885.

MR. EDITOR, — The recent excessive increase in the water-rates of Boston is a question which has a decided sanitary as well as economical bearing.

An abundant supply of pure water is *par excellence* a matter of necessity for the preservation of public health, and while the wasteful use of water

may be a proper subject of censure, on the other hand any measure which shall tend to diminish or restrict its abundant use, especially among the dwellings of the poor, should be heartily condemned.

While the excuse is urged that great manufacturing corporations should be favored, as an inducement to public prosperity, it is also true that the restriction that is sure to follow a decided rise in rates, either in its use for the ablution of houses, persons, clothing, utensils, or the flushing of streets and sewers, water-closets, baths, both public and private, of stables, etc., encourages the retention of filth and the consequent propagation of disease.

Especially at the present time is the measure ill-timed. With the more than probable advent of cholera in the United States during the coming summer in view, and also the history of its prevalence in Boston in 1832, 1849, and other years, in one of which alone, in a few weeks, six hundred died of the disease, it is desirable that every possible means of prevention should be employed. Cleanliness above all things is recognized as the most efficient weapon against cholera, and what better means can be adopted for promoting cleanliness than the liberal and abundant supply of water. The medical profession should heartily unite in opposing a measure so inimical both to public and private sanitation.

SANITAS.

### REPORTED MORTALITY FOR THE WEEK ENDING JANUARY 10, 1885.

Deaths reported, 2,478: under five years of age 872; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrheal diseases) 112; lung diseases 452; consumption 336; diphtheria and croup 181; scarlet fever 56; measles 40; typhoid fever 40; diarrheal diseases 27; whooping-cough 23; malarial fevers 18; purpural fever 10; erysipelas nine; typhus fever one. From *measles*, New York 28, Philadelphia and Boston one each. Brooklyn and Chicago two each. Fall River and Gloucester one each. From *diphtheria* diseases, New York 10, Charleston five, Boston and Baltimore four each, Chicago, District of Columbia, Holyoke, Taunton, and Fitchburg one each. From *whooping-cough*, New York six, Philadelphia, Brooklyn, and Boston three each, Chicago two, District of Columbia, Lowell, Lynn, Springfield, and Salem one each. From *malarial fever*, Brooklyn seven, New York six, Philadelphia, Baltimore, District of Columbia, New Haven, and Springfield one each. From *erysipelas*, Boston four, Brooklyn two, New York, Chicago, and Baltimore one each. From *puerperal fever*, Chicago three, Brooklyn two, New York, Boston, District of Columbia, Worcester, and Chelsea one each. From *typhus fever*, New York one. Cases reported in Boston, scarlet fever 62, diphtheria 31, measles 31, and typhoid fever nine.

In 104 cities and towns of Massachusetts with an estimated

population of 1,261,500 (estimated population of the State, 1,355,104), the total death-rate for the week was 1,362 against 1,380 and 1,743 for the two preceding weeks.

In the twenty-eight greater towns of England and Wales, with an estimated population of 8,762,354, for the week ending December 27th, the death-rate was 20.2. Deaths reported, 3,386: infants under one year of age 735; acute diseases of the respiratory organs (London) 370, whooping-cough 69, measles 67, scarlet fever 54, fever 34, diphtheria 28, diarrhoea 23, small-pox (London) 32, Liverpool three, Brighton one) 36. The death-rates ranged from 3.2 in Birkenhead to 32.2 in Leicester; Birmingham 20.8; Blackburn 19.4; Bradford 19.4; Leeds 20.2; Liverpool 25.0; London 18.6; Manchester 20.5; Nottingham 18.3; Sheffield 18.2; Sunderland 28.4. In Edinburgh 20.5; Glasgow 34.9; Dublin 26.6.

For the week ending December 27th, in the Swiss towns, there were 27 deaths from consumption, lung diseases 25, diarrheal diseases nine, measles nine, diphtheria and croup five, small-pox four. The death-rates were: at Geneva 20.4; Zurich 29.5; Basle 20.1; Berne 20.0.

The meteorological record for the week ending January 10th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps:—

Date.	Barom-eter.	Thermometer.				Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JANUARY 10, 1885, TO JANUARY 16, 1885.

HEAD, JNO. F., colonel and surgeon. Retired from active service, by operation of law, on January 9, 1885, under provisions of act of Congress approved June 30, 1882. S. O. 7, A. G. O., January 9, 1885.

McKEE, J. C., major and surgeon. Ordinary leave of absence still further extended four months, on surgeon's certificate of disability. S. O. 6, A. G. O., January 8, 1885.

BENTLEY, EDWIN, major and surgeon. Leave of absence extended two months. S. O. 8, A. G. O., January 10, 1885.

TIERMAN, W. S., major and surgeon. Relieved from duty at Fort Porter, N. Y.

GRUBB, A. C., captain and assistant surgeon. Ordered for duty at Fort Porter, N. Y.

APPEL, D. M., captain and assistant surgeon. Ordered for duty at Plattsburg Barracks, N. Y.

GRUBB, J. B., captain and assistant surgeon. Ordered for duty as post surgeon, Fort Schuyler, N. Y. H.

HAYVED, VALERY, captain and assistant surgeon. On being relieved at Fort Schuyler, authorized to avail himself of leave of absence (four months). S. O. 8, Department of East, January 12, 1885.

LEBRY, F. W., captain and assistant surgeon. Sick leave still further extended six months, on surgeon's certificate of disability. S. O. 9, A. G. O., January 12, 1885.

#### PROMOTIONS.

CAMPBELL, JOHN, lieutenant-colonel and surgeon, to be surgeon, with rank of colonel, December 7, 1884.

ALANSON, R. H., major and surgeon, to be surgeon, with rank of lieutenant-colonel, December 7, 1884.

McLEOD, HENRY, captain and assistant surgeon, to be surgeon, with rank of major, December 7, 1884.

APPOINTMENT. Jefferson R. Kean, to be assistant surgeon, with rank of first lieutenant, December 8, 1884.

#### SOCIETY NOTICE.

NORFOLK DISTRICT MEDICAL SOCIETY.—A meeting for scientific improvement will be held in "Social Hall" (Tremont Temple Building, Boston), entrance at 76 Tremont Street, on Tuesday, January 27, 1885, at 7.45 p.m. Fellows of the Massachusetts Medical Society are invited to be present and to join in the discussion. Subject for discussion: "The Management of the Living-in Mother After the Birth of the Child." Introduction by U. O. B. Wingate, M.D., of Wellesley, Mass.

Geo. D. Townsend, M.D., Secretary.

#### APPOINTMENTS.

BOSTON CITY HOSPITAL.—Dr. E. H. Bradford and Dr. Abner Post have been appointed visiting surgeons, at the Boston City Hospital, in place of Dr. W. C. B. Field, resigned, and Dr. W. H. Thorneick, deceased. The following gentlemen have been appointed in the Out-Patient Department: Dr. F. H. Brown, Diseases of the Ear; Dr. F. H. Hooper, Diseases of the Throat; Dr. G. H. Tilden, Diseases of the Skin; Dr. Morton Prince, Diseases of the Nervous System.

#### BOOKS AND PAMPHLETS RECEIVED.

Official Register of Physicians and Midwives now in Practice to whom Certificates have been issued by the State Board of Health of Illinois. 1877-1884.

A Contribution to the Relations of Ovulation and Menstruation. By A. Reeves Jackson, A.M., M.D. Chicago. (Reprint from the Journal of the American Medical Association, October 1, 1884.)

A CONSIDERATION OF THE MANAGEMENT OF PATIENTS DURING ETHERIZATION.<sup>1</sup>

BY H. L. BURRELL, M.D.

THE patient who for the first time subjects himself to anesthetization is usually filled with apprehension. He has heard that deaths have occurred under ether; of the horrors of suffocation inflicted during etherization, by surgeons crowding the ether; and that occasionally patients cannot be brought under the influence of the anæsthetic. He is to have an operation performed, a matter of great moment to most people. His life is in danger. He feels that he is passing through a crisis in his existence and all of his faculties are strained to their highest tension. Patients meet this situation with varying degrees of fortitude. They are in a helpless state, in which they place themselves in the keeping of another. This person is selected for his skill, experience, and good judgment. The surgeon for the time being holds an exalted position in the patient's mind. His every act, look, and word are noted and largely influence the patient's feeling of security.

The surgeon has the feeling, the result of experience and teaching, that there *is no danger*. Hence he is apt to pay but little attention to allaying the fears of his patient, who frequently believes that there *is danger*. The effect of this inattention is disquieting to the patient; for he feels that he is not being guarded against danger.

A composed, self-reliant man, who is to be etherized, is recognized as one that will give little trouble during anesthetization. The patient who is weak, vacillating, or whose nervous balance is easily jarred, may by injudicious preliminary treatment be unstrung and rendered a most uncomfortable subject for etherization. This may be largely prevented by a few words of assurance and encouragement and further by first administering the ether slowly and largely mixed with air.

We occasionally see the following plan of etherization pursued: The surgeon enters the room in a brusque manner; tells his patient to lie down on the bed; two or more strong assistants seize the already thoroughly alarmed patient; a junior surgeon is told "to etherize as rapidly as possible," while the surgeon turns away to some of his confrères and regales them with some professional tale or gossip. The patient meanwhile has a sponge, thoroughly saturated with ether, clapped on; attempts to draw a free breath, is choked; struggles, but is held fast; his face becomes turgid from the struggling and asphyxiation; he struggles again and again, until relief comes in the form of unconsciousness, by a union of etherization and asphyxiation. The two conditions of asphyxiation and etherization are not confounded by surgeons. The writer thoroughly believes that it is a lack of consideration, and not brutality, that occasionally allows this scene to be enacted. To take a child before it has reached the age of reason and "to crowd ether" upon it is humane; as it reduces to

a minimum the suffering, the struggle being quickly over.

It is a pleasure to see a man of tact and skill in etherizing change what may be made a very disagreeable experience into at least a bearable one. I have seen well-bred, trusting children of five years taken by a surgeon, told that they were going to be etherized and that they were to fear no danger, that they were to lie down quietly and breathe some ether and that they would soon go to sleep; that even if the ether did choke a little that they must keep right on breathing good long breaths, and that soon they would pass off into a beautiful sleep.

We rarely hear of any violent struggles occurring in etherizing private patients. The surgeon takes time. To be sure, he has a more intelligent person to deal with; he administers the ether slowly and in small amounts, recognizing that the cough and irritation of the fauces are signals to allow the patient to have fresh air.

When the patient arrives at the stage of excitement all recognize the need of pressing ether; but even in this stage he is not unruly and by a few sharp commands may be guided successfully over this height into the vale of unconsciousness beyond.

This paper is written for the purpose of drawing forth the practical points of individual practitioners, which, with them, are largely the result of experience. I will, therefore, make a series of propositions, which I trust will be freely discussed.

Before etherization, the surgeon should satisfy himself regarding the presence or absence of heart disease. The presence of serious regurgitation in a heart may not contra-indicate the use of ether in an "operation of necessity." In deciding the advisability of an "operation of expediency" it should enter as a factor. In any case the presence of serious heart trouble is a source of danger; and to the careful surgeon a matter of consideration. It is not necessary that each patient should be carefully auscultated; in most cases a glance at the patient, a few questions addressed, or the knowledge of the patient's previous life and habits, are all that is necessary.

The safety of the patient and the comfort of the etherizer largely depend on the use of pure anhydrous sulphuric ether. There are two principal manufacturers of ether. I prefer Squibb's. The kind of ether the surgeon is in the habit of using will be the most successful in his hands.

The best medium for administering ether is the one which can give the anæsthetic ether in a condensed form or largely mixed with air. We desire to use the ether largely mixed with air until the patient has become accustomed to its strangling effects; we wish to use it in a condensed form at the approach of the period of excitement.

In general, all inhaling apparatuses having automatic valves for the entrance of air should be condemned.

A sponge is open to the following objections: The difficulty of finding one of fine enough texture to exclude sufficient air and its wastefulness of ether. These difficulties may be partially overcome by moistening the sponge with water, and covering it with a towel. It is especially objectionable inas-

<sup>1</sup>Read before the Boston Society for Medical Observation, December 1, 1884.

much as it may have been used on persons having all sorts of disease, diphtheria as an example. My preference is a towel, stiffened by a newspaper folded within, in the form of a cone. This has the disadvantages of collapsing at times during etherization, and the cone may be made almost impervious to air. Its advantages are its readiness on all occasions and its cleanliness.

As a rule the patient should have a brief, clear description of the sensations he is about to experience.

This description would be contra-indicated in a class of hysterical patients and malingerers. It will, I feel sure, be of great assistance in warding off a struggle, especially in full-blooded, active men, for the last impression on their minds clings even into stupor.

A room free from bustle and confusion, before and after an operative procedure, is an essential for quiet etherization.

This is, perhaps, a matter of small moment, but in many patients it is the extra pressure that unbalances their nervous force.

The mental condition of a patient recovering from ether is one in which there is occasionally much suffering. This condition is best met by the admission of fresh, cool air, bathing the patient's head in cold water, and especially a freedom from obnoxious sights and sounds.

Ether should be administered on an empty stomach. This should not exclude a cup of coffee or of beef-tea, for we might weaken our patient by prolonged fasting: it is intended to apply to nourishment that may leave a solid detritus for vomiting. In certain debilitated cases a glass of liquor is particularly appropriate.

The knowledge of the effect of a glass of wine upon a patient is frequently an indication of the exciting or stupefying effects that ether may have. Dr. Thorndike tells me that he frequently asks the patient: "What is the effect of a glass of wine upon you?" If they answer that it excites them greatly, he anticipates trouble; if, on the other hand, they say that the wine stupefies them, he expects little trouble.

No mechanical impediment should exist to respiration. This means loose clothing about the neck, chest, and abdomen, the removal of artificial teeth or obturators.

Ether should be administered in a semi-recumbent position; the head should be thrown slightly forward and a little to one side, by a doubled pillow. At least the head should not hang backward.

The etherizer should do nothing else. He should hear every respiration and know of the heart's action. The sponge or towel may be steadied by the left hand, one finger of which may rest within the cheek. The right should rest on the temporal artery and may be used to supply fresh ether, to ascertain the conjunctival reflex, or the amount of lividity.

The pulse and respiration are the safeguards of etherization. One of the first signs of impending danger is the diminution of the force and frequency of the pulse-beat. It is surprising to observe with what certainty the force and frequency return on allowing a few inspirations of fresh air. The

sudden changing of arterial blood, in a wound, to a dark color, or the cessation of arterial spouting indicates approaching asphyxiation. This I have often seen illustrated by an operator stopping the administration of ether, without glancing at the patient's countenance.

One of the first symptoms of returning consciousness in protracted etherization is a long, deep sigh on the part of the patient: this is a signal for the administration of more ether, and has been observed by the writer to occasionally precede the return of the conjunctival reflex.

In the early part of etherization "a lull precedes a storm." In the first stage of etherization we may have a patient that is remarkably quiet, drawing short, superficial breaths which increase in frequency until they reach a climax; when apparently an explosion of nervous force takes place and violent struggling ensues.

The less ether used in an operative procedure the better the recovery of the patient.

The first effects of ether are stimulating. The secondary effects are decidedly depressing and I doubt not have occasionally turned the scale against the patient after a severe prolonged operative procedure. This subject was thoughtfully considered by Dr. G. W. Gay, in a paper on "The management of patients during capital operations,"<sup>2</sup> in which he says: "Use the least possible quantity of the anæsthetic, and allow the patient to rally early, depending upon opiates to control subsequent pain and inquietude."

A full dose of morphia administered an hour before etherization is largely used in certain localities, and it is said that "it quiets the nervous excitement of the patient, reduces the amount of ether otherwise necessary, and prolongs its effects, lessens the tendency to nausea and vomiting, and diminishes shock." I have had but slight experience in the use of morphia under these conditions.

A little ether in children goes a long way. It is remarkable to see how long children will remain etherized, and it is well to use a small amount and to frequently remove the anæsthetic entirely. The effects on young children of a given quantity of ether are usually out of all proportion to their age and size. We therefore must regard children as especially susceptible to ether.

Tongue forceps or the wooden gag are rarely necessary. The skilful management of the anæsthetic by the etherizer may largely prevent their use.

In complete anæsthesia the glottis may become stopped by the falling backward of the tongue. This manifests itself by a peculiar ineffectual pumping of the diaphragm and cyanosis. This closure of the glottis should be at once relieved by pushing the jaw forward, by the two forefingers or thumbs applied behind the angle of the jaw; this brings forward the tongue and thus opens the glottis and allows the entrance of air to the almost collapsed lung. A marked degree of swelling of the glands in the neighborhood of the angle of the jaw and persistent pain may result from the overzealous application of this useful procedure.

It certainly must be a very rare event, when a patient cannot be etherized.

<sup>2</sup> Boston Med. and Surg. Jour., October 11, 1883.

Lack of skill or timidity in the use of ether on the part of the administrator will probably explain all of the cases reported by the laity.

Under difficult etherization we may consider a class of patients who have been steady drinkers, who pass slowly under the influence of ether. As the patient approaches the period of excitement, he becomes livid, is seized with a succession of tremors, froths at the mouth, his jaws are set rigidly, and altogether he presents anything but a pleasant picture. Possibly we attempt to crowd the ether, or perhaps we wisely allow the patient to have more fresh air, the symptoms subside and we again press the ether; the same tetanic state ensues and we again allow the entrance of more air. This state of affairs frequently continues until the operative procedure is finished, the patient never being fairly etherized. It has been my experience that when one meets such a patient, the best course to pursue is to first crowd the ether: failing in this, to allow the patient to come almost entirely out from under the influence of the anæsthetic, so that he sits up, looks about, vomits, or thoroughly clears the whole of his respiratory tract; then make a new start with fresh ether and frequently the patient will quickly become profoundly etherized.

As a result of this consideration we have certain propositions which I take it all will accept. They are:—

First, Before etherization, the surgeon should satisfy himself regarding the presence or absence of heart disease.

Second, The safety of the patient and the comfort of the etherizer largely depend on the use of pure anhydrous sulphuric ether.

Third, The best medium for the administration is one in which the ether can be given in a condensed form or largely mixed with air.

Fourth, As a rule the patient should have a brief, clear description of the sensations he is about to experience.

Fifth, A room free from bustle and confusion before and after an operative procedure is an essential for quiet etherization.

Sixth, Ether should be administered on an empty stomach.

Seventh, The knowledge of the effect of a glass of wine upon a patient is frequently an indication of the exciting or stupefying that ether may have.

Eighth, No mechanical impediment should exist to respiration.

Ninth, The pulse and respiration are the safeguards of etherization.

Tenth, The less ether used in an operative procedure, the better the recovery of the patient from the immediate effects of the operation.

Eleventh, A little ether in children goes a long way.

Remaining we have a number of questions on which possibly there is difference of opinion. The following suggest themselves to my mind:—

The comparative value of the different brands of ether?

Whether it is better to pull the tongue forward or to push the jaw forward?

Whether any patient exists that cannot be etherized?

The comparative values of a sponge, towels, and inhalers?

The use of opiates and stimulants as adjuncts to etherization.

## FIVE CASES OF OVARIOTOMY.<sup>1</sup>

BY J. W. ELLIOT, M.D.,

*Assistant Surgeon in the Free Hospital for Women.*

CASE I. was referred to me by Dr. J. J. Minot. Mrs. S., widow, aged thirty-two; had one child five years old. She complained of an enlarged abdomen, irregular catamenia, and constipation. She had first noticed a slight abdominal enlargement one year before. It had grown rapidly of late and was unfitting her for work. Her general health was poor. The tumor was quite large, filling nearly the whole abdomen. It was fluctuating and could easily be felt in Douglas's fossa pushing the uterus up behind the pubes. The right broad ligament was very resistant.

At the operation a large part of the tumor was easily removed, but one cyst-chamber and a mass of solid matter were deeply and firmly imbedded between the folds of the right broad ligament. This part of the tumor was with difficulty enucleated, the peritoneum being extensively lacerated. The whole broad ligament formed the pedicle and was ligatured close to the uterus in two separate parts. The left ovary being enlarged was also removed. Drs. Cabot, Watson, Strong, and Kennedy kindly assisted me. Dr. Baker was present. The patient made a good recovery. The stitiches were removed on the tenth day, when the wound was found united by first intention without a drop of pus. The highest temperature was 101° F. The patient did not walk for several weeks on account of a slough on the feet caused by the careless use of a hot-water bottle.

CASE II. — Mrs. C., aged forty-nine, had had two children and a miscarriage. I first saw her with Dr. F. W. Johnson. She was in miserable health, complaining of a swollen abdomen, profuse flowing, frequent micturition, and pain in her left side. Six months previous she had consulted a physician on account of flowing and had been told that she had a fibroid tumor of the uterus. Three months later Dr. Johnson found her still flowing. At that time he could easily feel a very hard, small tumor, which he then supposed to be a fibroid. One month later the abdomen had increased enormously in size and the tumor fluctuated. Early in March she entered the Free Hospital for Women. The tumor then distended the whole abdomen as high as the sternum. The uterus was retroverted and fixed. A sound could not be passed. In view of this exceptional history, the whole tumor having grown within nine months and most of it in one month, we drew off three quarts of fluid with the aspirator for diagnosis. This fluid was characteristic of ovarian tumor.

At the operation a large dermoid cyst was found containing hair, bone, fat, skin, and teeth. There were few adhesions and the tumor was easily re-

<sup>1</sup>Read at the Surgical Section of the Suffolk District Medical Society, January 7, 1885.

moved. Drs. Cabot, Johnson, and Strong assisted; Drs. Homans and Watson were present. The patient made a rapid recovery. The highest temperature being 99.8° F. The wound healed by first intention without a drop of pus. Nine months after the operation she writes to Mrs. Wilson, her nurse, that she is in excellent health and has had no more flowing.

CASE III. occurred in my own private practice. Miss M., aged twenty-two, complained of pains in the back, loin, and lower abdomen, also of intense dysmenorrhea. Four years ago was confined to the bed for six months with an attack of inflammation of the bowels. Since that time she has been an invalid and has been treated by various physicians for "chronic inflammation," without the least improvement. When I first saw her she was fat and anemic, and was utterly unable to do anything on account of a pain through the lower abdomen, which always came on after she had been standing a few minutes.

On bimanual examination a fluctuating tumor—size of a large cocoanut—was distinctly felt filling the anterior part of the pelvis and crowding the uterus back against the sacrum.

The operation proved exceedingly difficult and tedious. The abdominal walls were very thick and the muscles rigid. The cyst had a thin wall and was firmly adherent in every direction. In tearing away the adhesions the cyst was ruptured and its dark chocolate-colored contents escaped into the abdominal cavity. The ovarian artery was then ligatured and the cyst-wall came out in shreds after a tedious dissection. There was no pedicle, so the whole broad ligament was tied with three ligatures close to the uterus. The pelvic cavity was full of bands of adhesions so that Douglas's fossa appeared to be closed and the other ovary could not with certainty be made out. The uterus was firmly bound to the left side. It was impossible to thoroughly clean the abdominal cavity. The operation lasted one and one-half hours. Dr. Johnson was my only assistant. Dr. Clark etherized. The patient recovered somewhat slowly. On the fifth day the temperature rose to 101° F. The dressings being removed an abscess was found in the abdominal wound which was opened by removing the stitches. The wound then healed by granulation. The patient was well in six weeks.

CASE IV. was referred to me by Dr. John Homans, at first for diagnosis and afterward for operation. Miss L., aged twenty-four, had been sick for three years. She complained of pain in the back and general languor, had had sudden and severe pains in the lower part of the abdomen, also sudden attacks of flowing, followed by amenorrhea for several months. She had been told by five different doctors that she had a tumor which could not safely be removed. She was so much depressed by this, and by her sufferings, that she had lost flesh and strength and thought that she should die. She was determined to have it removed if it was possible.

Examination revealed a hard tumor larger than a hen's egg in the hollow of the sacrum somewhat to the right side. The uterus was three and a half inches deep and in left lateral retroversion. The

tumor and uterus seemed to be one mass. The tumor was very hard and perfectly immovable. It was exceedingly difficult to decide what the tumor was and to what organs it was attached. To help solve this problem I gave my patient ergotin pills until the uterus became much contracted and very hard. The result was astonishing. I was then able to feel that the uterus was harder than the tumor and of a distinctly different consistency. This enabled me to decide that the tumor was not growing from the uterus, but was only crowded against it. After watching the case for three months I decided that the tumor was either ovarian or an enlarged Fallopian tube, but probably ovarian.

The operation was done at St. Margaret's Home. I found a dermoid tumor of the right ovary as large as two fists, a part of which was nearly solid, being filled with hair and fat. There was some difficulty in removing it on account of its being tightly wedged in the pelvic cavity.

She made a quick recovery, having no unpleasant symptoms. The temperature was normal on the fifth day. The stitches were removed on the ninth day, when the wound was found to have healed by first intention without a drop of pus. She sat up on the fourteenth and went home on the twentieth day.

CASE V. occurred in my own private practice. Mrs. M., aged twenty-eight, complained of chronic inflammation, sterility, etc.

Bimanual examination revealed a cyst—size of a cocoanut—in front of the uterus.

The operation was very simple. The cyst contained clear fluid and proved to be of the left broad ligament. It was removed through an opening in the peritoneum less than two inches long. There were adhesions to the intestines and omentum. The ovary and Fallopian tube being both enlarged were removed with the cyst. The pedicle included the whole broad ligament and was ligatured close to the uterus.

The patient made a rapid recovery, the highest temperature being 100° F.

The wound healed by first intention and the patient went home on the twenty-first day.

These cases and one exploratory incision elsewhere reported, together with about one hundred other cases where I have acted as assistant, complete my experience in laparotomy up to January 1, 1885.

CASE II. is interesting because uterine hemorrhage was a prominent symptom.

In cases III. and V. chronic inflammation was the prominent symptom, and was supposed to be the only trouble until a small tumor was discovered. This suggests that tedious cases of chronic inflammation should be carefully investigated.

I am not aware that ergotin has ever before been used in exactly the way it was in case IV. for diagnosis. Since then I have used it several times with satisfaction. It makes the uterus much harder and thereby exaggerates any difference in consistency between the tumor and uterus; also, the contractions of the uterus seem sometimes to draw it away from the tumor so that the examining finger can be pushed further in between the two. If the tumor is a part of the uterus, it hardens with the uterus.

I have carried out the known antiseptic precautions with the greatest possible care. Corrosive sublimate 1 to 1,000 has been used for cleaning hands, sponges, ligatures, etc. So far I have always used the carbolic spray, although I do not consider it essential.

It is needless to say that I am strongly in favor of early operations, three of these operations having been done for small tumors. Although the reasons for early operations are well known, I will allude to them here in order to sustain my position on this point. There is a gradual decline in the general health as the tumor grows larger. The benign tumor is liable at any time to take on a malignant character. This really occurs much more commonly than was formerly

supposed. Other things being equal there are more extensive adhesions with large tumors. Long-continued pressure from a tumor often causes enlargement and malposition of the uterus, partial occlusion of the ureters and the consequent kidney complications, misplacement and derangement of the bladder with consequent cystitis and remote nephritis. Then there are the accidental complications of twisting the pedicle, suppurative of the cyst, rupture of the cyst, acute peritonitis, thrombosis and embolism, pregnancy, concurrent diseases, etc., which may occur at any moment. There are difficulties in removing small tumors which do not occur with large ones, but on the whole the operations may fairly be said to be less severe.

TABLE.

No.	Age.	Date of Operation. 1884.	Place of Operation.	Length of Incision. Inches.	Adhesions, etc.	Size of Tumor.	Result.	Remarks.
1	32	January 26th.	Free Hospital for Women.	5	Deep enucleation from right broad ligament.	15 lbs.	Recovered.	Both ovaries removed.
2	49	March 31st.	Free Hospital for Women.	3½	Few small adhesions.	20 lbs.	Recovered.	Dermoid cyst.
3	22	October 14th.	Free Hospital for Women.	4½	Very firm and extensive in every direction.	Size of cocoonut.	Recovered.	Thin-walled cyst.
4	24	October 28th.	St. Margaret's Home.	4	Tumor tightly wedged in pelvic cavity.	Size of two fists.	Recovered.	Nearly solid. Dermoid.
5	28	November 22d.	Free Hospital for Women.	2	Adhesions to intestines and omentum.	Size of cocoonut.	Recovered.	Cyst of broad ligament.

## REPORT ON OBSTETRICS.

BY CHARLES M. GREEN, M.D.

## MEMBRANOUS INSERTION OF THE CORD: HYDRAMNIOS AND FETAL ASCITES.

Truzzi reports<sup>1</sup> an instructive case from the clinic of Professor Porro, in which the appearances were membranous insertion of the umbilical cord, hydramnios, congestive hypermegalia of the liver and spleen, ascites and oedema of the great epiploön, cerebral oedema and serous infiltration of the subcutaneous cellular tissue of the head and thorax. Venous stasis in the feto-placental circulation was clearly the cause of these alterations, and the stasis was due to membranous insertion of the cord and the consequently long course, partly membranous, partly placental, of the ramifications of the umbilical vessels. The author does not, of course, assert that membranous insertion of the cord necessarily results in serous effusions; but he thinks that the coincidence of hydramnios and fetal ascites with membranous funic insertion is not merely fortuitous. The feto-placental circulation is, of course, carried on less easily when the vessels of the cord are spread over the membranes, and the increased resistance to the blood current may exaggerate the serous exosmosis which is supposed to produce, in part at least, amniotic fluid; when, therefore, this resistance is sufficiently great, the natural result of the membranous insertion would be hydramnios and the other serous effusions which the author found in the case reported.

## THE TREATMENT OF ABORTION.

Schwarz, of Halle, has written a very comprehensive treatise<sup>2</sup> on this subject, in which he first speaks briefly of the prophylaxis and then considers in detail the treatment of abortion already in progress.

When there exists a preëxisting tendency to abortion Schwarz believes that only in the rarest instances can premature expulsion of the ovum be averted by continuous lying in bed, by giving up the usual occupation, and by the careful avoidance of all external circumstances and conditions usually considered prejudicial to the pregnant state; the reason being that only exceptionally are the effective causes of abortion external, but in the great majority of cases are to be found in abnormalities of the internal reproductive organs, or in general affections, especially syphilis. The most favorable time, therefore, for the successful exhibition of prophylactic treatment is before impregnation has taken place, attention being directed to the correction of structural anomalies, malpositions of the uterus, especially backward displacements, and inflammation of the endo- and peri-metrium. Schwarz calls especial attention to another factor which he has found to be a frequent cause of abortion, namely, deep lacerations of the cervix, and he points out the importance of repairing such lacerations as a prophylactic measure. After conception has taken place Schwarz believes there is but little opportunity for active prophylaxis, except in correcting uterine displacements and in the treatment of syphilis.

Coming then to the treatment of already im-

<sup>1</sup> Gazz. Med. Ital. Lombardia, April 5, 1884, and the London Medical Record, July 15, 1884.

<sup>2</sup> Volkmann's Sammlung Klinischer Vorträge, No. 211.

pending abortion, Schwarz endeavors to lay down certain rules by which it may be determined whether or not the abortion can probably be prevented. He thinks the condition of the cervix affords one of the surest signs: if the cervix permits the passage of the finger through the internal os, if also the lower pole of the ovivac is within reach and is forced down into the upper part of the cervical canal, or if, in the case of primipare, although the external os is still impassable, the cervix is already taken up and forms with the uterine body a common cavity, then the expulsion of the ovum is beyond question. A foul vaginal discharge, indicating the probable death of the ovum; or a considerable hemorrhage lasting several days, especially if accompanied by dull or cutting pains in the sacral region, are almost infallible signs. If a reasonable hope of preventing the expulsion of the ovum exists, the end is to be sought by enforcing the greatest possible bodily and mental rest, and by the free use of opium. If, however, abortion is inevitable, expulsion of the ovum should be hastened as much as possible, with the view of keeping the attendant dangers within bounds.

The dangers against which in abortions one has to contend are hemorrhage and septic degeneration of the ovum. If the ovivac has not ruptured, Schwarz recommends the cervico-vaginal tampon as an absolutely sure means of arresting the severe hemorrhage which almost without exception accompanies the expulsion of the ovum in the first half of pregnancy. As soon as the hemorrhage shall have been controlled, the tampon should be removed, and the vagina cleansed and disinfected. A cotton wad sprinkled with iodoform should then be placed against the cervix and held in position with a vaginal tampon. Thus protected against hemorrhage and septic infection the patient can be left for from eighteen to twenty-four hours: the tampon usually increases the pains and thus promotes the dilatation of the cervix and the expulsion of the ovum. If, however, by this treatment inconsiderable progress is made, Schwarz is accustomed to administer an intra-cervical douche to the amount of two or three liters of a cold antiseptic fluid, using for the purpose a catheter suitably bent and provided with lateral openings. The object of the douche is not so much to dislodge the ovum as to awaken uterine contractions, and the author has found cold irrigations more effective than hot, which latter have sometimes apparently produced paralysis of the uterine muscle. If alternate use of the tampon and the cold irrigation does not effect the desired result, Schwarz then resorts to laminaria tents carefully disinfected and sprinkled with iodoform. Should, however, this method appear too tedious on account of the invasion of fever or beginning degeneration of the ovum, or if for any reason the uterine contractions are not sufficiently powerful to expel the ovum, Schwarz recommends the dilatation of the cervix with Fritsch's dilators, the separation of the ovum with the finger, and removal with finger or forceps as appears most convenient.

If at the time that treatment is to be instituted the ovivac has ruptured, an entirely different method is to be pursued. Rupture of the sac, if not positively recognized by escape of the liquor amnii

and expulsion of the fetus, can be diagnosed with great probability from the diminished size and elasticity of the uterus. In cases of ruptured ovivac, then, the tampon is not to be used, unless provisionally, on account of the danger of concealed hemorrhage, especially in abortions after the fourth month, and of septic infection from degeneration of retained blood clot or decidua; but if the cervix is not already passable for the finger, it should be immediately dilated manually or instrumentally and the uterus speedily emptied of its contents. When there exists pelvic effusion or recent inflammatory action this should be done with the greatest gentleness and all instrumental interference avoided if possible. The curette is often of the greatest service, especially in cases in which persistent hemorrhage points to the probable retention of a bit of decidua or placental tissue: the value of subsequent styptic injections of iron or iodine is pointed out by Schwarz, together with many valuable suggestions as to detail in the treatment of this anxious class of cases.

#### PROPHYLAXIS AND TREATMENT OF PUERPERAL FEVER IN THE DUBLIN ROTUNDA.

In his report<sup>3</sup> of the Rotunda Hospital for the year 1883, the master, Mr. Arthur V. Macan, very clearly gives his views on the etiology of puerperal fever and tersely explains the methods adopted by the hospital for the prevention and treatment of this dreaded malady. He accepts the theory first enunciated by Semmelweis in 1847, "that puerperal fever is caused by the absorption of animal matter in a state of decomposition," and divides cases into two great classes—those caused by auto-infection, in which the poison is generated within the woman, and those due to hetero-infection, or the introduction of poison from without. The hetero-genetic cases occur most frequently in primipare, after, in most instances, a quite normal labor: "the symptoms come on suddenly, within about thirty-six hours of delivery, and at the outset the discharge is not fetid." In this case the poison has been inoculated much like that of snake-bite or like vaccine virus in vaccination, and like the latter has a very constant period of incubation. In such cases little benefit can be expected from the local application of antiseptics, as the poison has infected the whole system, and the result depends largely upon the amount and virulence of the inoculated poison.

The auto-genetic cases, on the other hand, occur most frequently in multipare after a long labor or one complicated with a putrid fetus, a fibroid or cancerous tumor, or with post-partum hemorrhage, retention of clots, bits of membranes or placenta. In these cases a badly contracted uterus and lax abdominal walls favor the entrance of air and the consequent decomposition of the contents of the womb. A fetid discharge is thus produced, which may not infect the patient if it has a free escape, but which, if absorbed into the system from imperfect drainage, causes the condition designated by Matthews Duncan as sapremia or putrid absorption. In this class of cases, in marked distinction from those caused by septic inoculation, great benefit

<sup>3</sup> Dublin Journal of Medical Science, June, 1884.

follows the use of local disinfectants and the establishment of free drainage.

The prophylactic precautions against hetero-infection adopted in the Rotunda embrace strict antiseptic of everything that comes in contact with the patient, — the examining finger, the instruments, the bed-linen and napkins. The rubber catheter has given place to one of silver, which after use is kept for some time in a hot evaporating carbolie solution: vaginal and uterine tubes are of glass, and each patient is provided with tubes for her exclusive use. To guard against the injection of air into the uterus or vagina, which, besides being dangerous in itself, is liable to cause fetid lochia and subsequent auto-infection, syringes have been replaced with irrigators which act by gravity. Before every operation the vagina is irrigated and the external genitals carefully washed with a solution of corrosive sublimate, 1 in 2,000: the uterus is syringed out afterward and a pessary containing 5jss of iodoform is placed within its cavity. Vaginal examinations are made as infrequently as possible, diagnosis of position and presentation being made largely by careful abdominal palpation. If these precautions have been carefully carried out, the patient must be supposed to have thus far escaped hetero-infection, and there can be no necessity for prophylactic antiseptic injections, either vaginal or uterine, during the puerperium; but the genitals should be washed twice daily with plain warm water and a piece of oakum. Regarding the treatment of hetero-genetic infection Macan has very little to suggest, as he knows nothing that will quicken the elimination of the poison from the system. When a continuously high temperature begins to show its effect on the nervous system he would employ antipyretics, preferably quinine in large single doses of from ten to twenty grains, or the bath at 90°F. cooled gradually to 60°, together with alcohol in large quantities.

The two conditions essential to auto-infection are first a fetid discharge and second its retention within the genital tract. In order that the natural discharge should become fetid, air must have entered the uterus: hence the prophylaxis of auto-infection should consist primarily in preventing the entrance of air and secondly in removing any fetid accumulation within the uterus, disinfecting its cavity and providing for free drainage. Macan points out the great danger of the entrance of air in multiparae with lax abdominal walls, especially if they are allowed to lie upon the side during the third stage, and the uterus is not properly supported and good contraction subsequently maintained. A rational prophylaxis, therefore, dictates that after the birth of the child the patient should lie on her back, as in this position the intra-abdominal pressure upon the uterus is greatest and there is less liability of air being drawn into the genital canal by negative pressure. The fundus should be properly supported and firm contraction obtained with the aid of ergot and, if necessary, hot antiseptic injections. A binder should be firmly applied and the patient should maintain a dorsal position for several days, as in this position natural drainage is better attained. But if, in spite of these precautions, the lochia become fetid and the tempera-

ture becomes high and remains so for twenty-four or thirty-six hours, antiseptic intra-uterine treatment should be immediately instituted: the uterus should be washed with a 1 in 2,000 solution of corrosive sublimate and an iodoform suppository should be placed within the cavity. The great value of this use of iodoform is strenuously asserted by Macan, who has obtained with it the most gratifying results, not only from its antiseptic properties, but from its powerful effect as an antipyretic.

As a result of the careful prophylaxis thus briefly described, the master is able to show a mortality rate of only 0.55 per cent., and this rate comprises the total mortality from all causes, not alone of the period of labor, but of the puerperal state.

#### THE TREATMENT OF THE NAVEL IN THE NEWBORN.

Credé and Weber, in the first <sup>4</sup> of a series of communications from the obstetric clinic in Leipzig, consider this subject with reference to two dangers which threaten the child:—

(1) Secondary hæmorrhage from the umbilical cord.

(2) Inflammation of the navel itself.

With the establishment of pulmonary respiration and the concomitant changes in the circulation of the newborn child, pulsation in the cord becomes weaker and weaker and, in from five to ten minutes, ceases: under normal circumstances no hæmorrhage follows the cutting of the cord after pulsation has ceased, as experience among animals shows, and it has been proposed at various times that ligation of the cord be dispensed with. The proposition has not met with favor, however, because of the danger of secondary hæmorrhage, which may ensue hours or even days after birth, under circumstances which cause increased activity of the heart or disturbances in the venous circulation.

Regarding the exact time when the ligation should be applied to the cord authorities are not agreed, because it is not exactly known how much of the total quantity of blood contained in the fetus and placenta belongs physiologically to the child. It is certain, however, that immediate ligation is not advisable, because thereby a considerable quantity of blood would be lost to the child. It is unnecessary to wait for complete cessation of pulsation, but until the pulsation is weak and the umbilical vein has collapsed: this would be under ordinary circumstances in from three to five minutes, when the child has cried lustily several times.

But of greater importance than the time when the cord should be ligated is the material with which it is tied. The linen string ordinarily used has not given satisfaction in the Leipzig clinic, where secondary hæmorrhages of various degrees have occurred almost every week. The authors have repeated the experiments of Budin and tested the efficiency of linen ligatures on fresh cords by injecting the latter with water under various degrees of pressure. It was found that with a single ligature on a cord rich in Wharton's jelly a moderate pressure sufficed to inject water through the point of ligation. Strong pressure was followed by a like result when the ligation was wound two, three,

<sup>4</sup>Archiv für Gynäkologie, Band cxiii. Heft 1.

and four times around the funis and tied as firmly as possible. The longer the time that elapsed between the application of the ligature and the injection of the cord, the less the pressure required to force water through the point of ligation. In other words it was found in the authors' experiments that with the shrinking of the struma of a richly gelatinous cord the ligatures were so loosened that they could easily be slid from the point of application or turned around in a circle. Tarnier reports a case in which he observed hæmorrhage from a richly gelatinous cord a very short time after applying three firm string ligatures. Various expedients and materials have been from time to time suggested by which it has been sought to tie the cord securely; but the material which to the authors seems best to stand the test of experience is caoutchouc, originally proposed for this purpose by Budin. The authors have used small bands of this material, or slender rubber drainage tube, in their Leipzig clinic since July, 1883, and not a single case of secondary funic hæmorrhage has occurred. A band about eight inches long and one twelfth of an inch thick (or a piece of rubber drainage tube of corresponding strength) is applied to the cord in the manner shown in the figures, firmly tied and the ends cut short.

The authors have demonstrated to their satisfaction that with this ligature well applied secondary hæmorrhage is impossible, since owing to its elasticity the ligature fits itself to the shrinking cord and exerts a continuous pressure. As a single ligature is sufficient, it can be applied quite near to the umbilicus; this is an advantage not to be undervalued, for the shorter the residual cord, the less the danger of traumatic inflammation of the navel.

The subsequent treatment, which the authors

believe best calculated to prevent moist gangrene and septic inflammation of the navel, consists simply in enveloping the short residual cord in common absorbent cotton and applying the usual abdominal band. After the morning bath the cord is to be carefully dried, and fresh cotton applied: the process of mummification is thus promoted and the cotton acts as an excellent barrier to septic germs. The results from this treatment in the Leipzig clinic have been extremely favorable, and since its adoption inflammation of the navel has not been observed.

#### EMPHYSEMA OF THE NECK OCCURRING DURING LABOR.

Mr. F. H. Champneys (London) has made an experimental inquiry into this subject and reported his results to the Royal Medical and Chirurgical Society at a recent meeting.<sup>5</sup> It appears that the accident occurs about once in two thousand labors and is caused by the violent and prolonged expiratory efforts of the second stage. The emphysematous swelling appears first at or about the suprasternal notch, whence it may extend in all directions: the air is absorbed within a week or so, and the cases always end favorably.

In making his experiments Mr. Champneys used healthy fetuses (with two exceptions): tracheotomy was performed and the trachea connected by a T tube with a mercury manometer, leaving an open tube for inflation. Some of the experiments were performed with the lungs in situ, others with the thorax open, others with the lungs removed from the chest. The conclusions from the experiments were the following:—

"(1) The cause of emphysema of the neck during labor is rupture of the lung tissue, the air escaping near the root of the lung, passing beneath the pulmonary pleura into the anterior mediastinum, and so beneath the deep cervical fascia into the neck."

"(2) The weakest parts of the lung are opposite the pleural reflections, that is, the spaces between the lobules and the fissures between the lobes, and especially the anterior surface of the root of the lung."

"(3) Pneumothorax, when it occurred during experiment, had nothing to do with the production of emphysema of the neck. The healthy bronchi and trachea are able to resist the greatest possible expiratory efforts."

"(4) The lungs and pleura, when quite air-tight, are freely permeable to liquids."

"(5) The usual rules of practice, to restrain bearing down and accelerate labor after the production of emphysema, are sound."

"(6) The accident would seem to be noted in about one case in two thousand; but it is not improbable that slight cases are overlooked."

"(7) The air emerges from the thorax along the great vessels, but may not become superficial till it has traveled higher up."

"(8) The emphysema of the lower part of the trunk, usually connected with rupture of the uterus, belongs to quite a different category, and is generally associated with a fatal result."

## Therapeutic Memoranda.

### COCAINE DISCS.

#### A CONVENIENT FORM FOR ADMINISTRATION.

BY JOSEPH W. WARREN, M.D.

A FEW weeks since I suggested to MESSRS. Metcalf & Co. that gelatine discs, impregnated with *cocaini hydrochloras* would probably prove a great convenience in local applications. After several experiments as to details of manufacture they finally sent me a delicate sheet of little squares, each containing one twenty-fifth of a grain (0.0026 gm.), or about half a drop of an 8 per cent. solution. A trial of these convinces me that this form of administration will be exceedingly satisfactory, not only especially for all work on the eye, but also in many other portions of the body where local anesthesia is required. The advantages of the method are in the economy and convenience of dosage (since there seems to be no danger of poisoning from any of the usual dilutions), in exactness of application, and in the ease with which the drug may be carried.

## Reports of Societies.

### BOSTON SOCIETY FOR MEDICAL OBSERVATION.

CHARLES H. WILLIAMS, M.D., SECRETARY.

DECEMBER 1, 1881. DR. H. L. BURRELL read a paper on

#### THE MANAGEMENT OF PATIENTS DURING ETHERIZATION.<sup>1</sup>

DR. H. DERBY said: The state of mind in which the average patient approaches etherization is, in my opinion, too often not considered. Artificial insensibility to pain seems to the surgeon so eminently desirable, its production so much a matter of course, and too often of routine, that he is very apt to forget that his patient may entertain very different feelings on the subject. And this is true not only of the lower classes and the uneducated, but it is a factor to be taken into account even with the most intelligent.

The repugnance of the ordinary hospital patient to ether is easily understood. Even when he has never yet taken it himself, he has come in contact with plenty who have. He knows the operator's time is limited, and that one has to be made insensible as quickly as possible. He has heard all about the restraint that has been put upon him, the attendants who will control his struggles, the sponge jammed close to his face, the short spasm of suffocation. He naturally dreads the process, and is apt to object even more strenuously to its repetition.

Then there are many, belonging to a class superior to the foregoing, who are convinced either that some organic defect prevents them from taking ether, or whose experience with some dentist has been unsuccessful. They are convinced that they

cannot be brought under the influence of the agent, or that the consequence of its administration will be fatal. That this is more than a mere notion the following anecdote will illustrate. Some years ago I had to remove an eye from a young man of twenty or thereabouts, of foreign birth. He dreaded the operation not at all, the ether vastly. His friends assured him it was his duty to submit himself to me unreservedly and he did so, I assuring him there was not the least danger. As he was coming out of the ether some peculiarity about what I had thought to be his nightdress arrested my attention. It turned out that, so firmly had the poor fellow believed his last hour had come, he had prepared himself for death according to all the rites of his faith and gone to bed with his grave-clothes on, in order to save the family the trouble of putting them on afterward.

Finally, analogous to the vague dread of physical death, so firmly implanted in our nature, is the repugnance to the voluntary surrender of consciousness. This is the feeling most thoroughly developed in the highly educated; and frequently requires great strength of will to overcome. From all this it results that, no matter who the patient, etherization will be more easily effected if pains be taken to mitigate the fear felt by almost every one toward it, and that a greater effort should be made than generally is to render its administration as easy as possible. The patient should be assured, in the outset, that ether may be given and sleep produced with as much ease, or nearly so, as a nurse puts a tired child to sleep. And his confidence, thus acquired, will be strengthened if he takes the ether from the hand of the surgeon with whom he is already acquainted, instead of having it administered by a strange assistant.

My own custom is to have nobody in the room except the nurse, in rare cases a single friend if the patient insists upon it. After telling him to dismiss from his mind any apprehension of danger as utterly idle, I tell him that the first contact of the vapor with the lungs is apt to be a little irritating, and that he will be strongly tempted to put up his hand and push away the napkin, a movement I particularly desire he will avoid; promising him, at the same time, that if he formally requests it, I will remove the ether from his face at any moment. Often after this there is no attempt to rid himself of the ether, no disposition to struggle. I use a napkin folded as a cone, both to economize the ether and to avoid the necessity of turning as the fluid gravitates, a most annoying thing about the sponge. This napkin is never crowded down on the face the first thing, a proceeding as inhuman as it is unnecessary and sure to involve a struggle. On the contrary it is held at first a short distance from the face, and then gradually approached as the patient gets used to the fumes of the ether. After a short time has elapsed a very general remark on the part of the patient is something like the following: "Doctor, I'm not asleep yet." "Don't you think I'm hard to affect?" "Promise me you won't touch me till I am off." These apparently trivial sayings are mentioned as indications of a feeling very frequently met with at this stage, a suspicion on the part of the patient that the surgeon is

<sup>1</sup> See pages 97-99.

getting dissatisfied with the slow rate at which the process is going on, and is on the point of administering the ether at a more rapid rate, or cutting off the supply of air. It is, therefore, now that an assurance that everything is going on perfectly well, and that there is absolutely no hurry, is of the greatest value, and the patient, on its being given, often sinks off contentedly to sleep.

Early in the etherization I always watch the patient's hands. If he half consciously puts them up to brush away the napkin, I speak pleasantly but decidedly to him, and request him to take away his hand, and even to put it back under the bed covering. If nothing less will satisfy him, I even remove the napkin for an instant. It is often found that all he wishes is to clear his throat; which, once accomplished, perfectly contents him. I seldom use the slightest force in the way of restraint, and I regard this maxim as the secret of peaceable and pleasant etherization. Look out for the medical spectator, if one happens to be in the room. Before the patient has raised his hand half way up to his nose, he has him pinned by both wrists. Every evil passion in the patient's nature is at once roused, and a severe struggle is apt to ensue; a thing wholly unnecessary if a little tact had been employed.

I am far from saying that there are not exceptional cases, met with among hysterical women, fighting characters of the male sex, and the like, where some constraint may not have to be employed before perfect insensibility is produced. But such instances are few and far between, and can generally be anticipated. I then direct a ward-tender to wait outside the door, but never let the patient know he is in waiting, and in the majority of instances do not have to employ him.

In brief, a little patience with human ignorance and weakness, a little kindness, a good deal of firmness, and an entire absence of assistants, ward-tenders, and apparatus, and a willingness to spend a little extra time, are all that is needed to bring about an etherization that is not only reasonably pleasant in itself, but leaves the patient willing to go through the thing again; a result not always to be met with in these days. Let the patient be treated as a human, reasonable being, both before and after the process, and not like an irresponsible and dangerous lunatic.

Dr. O. F. WADSWORTH had found it of use to ask questions of the patient when the state of excitement begins, and insist on an answer, as a means of diverting his attention.

Dr. E. G. CUTLER said that the tongue can be kept out of the way by holding up the chin. It is also necessary to see that the patient is well covered, as perspiration is often abundant, and in weak patients the exposure to cold is an element of danger. The sponge or towel should be frequently wrung out to remove the old ether. He has found Powers and Wightman's ether less irritating than Squibb's.

Dr. E. D. SMITH recommended using some stimulant, such as ammonia, in every case. Dr. BERRY had found that bromides beforehand made the patients easier to etherize and quieter afterward. Dr. C. B. PORTER takes off the sponge during each

expiration, and so brings the patient to feel that he is getting a chance to breathe; when the mouth is forcibly opened, a spasm of the glottis is sometimes observed, perhaps from the ether getting into the mouth and throat. He does not like paper cones, and prefers Powers and Wightman's ether, as less irritating. He prefers to hold a finger in the side of the mouth to pull the chin forward and keep a free passage open for breathing; as, when the chin is pressed forward, an unconscious pressure is often made on the throat, which is bad. Frothy mucus is a great difficulty, but he has never seen a patient who could not be etherized.

Dr. E. H. BRADFORD spoke of the stage of primary anaesthesia as being very good for small operations, shown when patient could no longer hold up his hand. He had seen Mr. Clover administer laughing-gas, followed by ether, without a struggle. He considered Squibb's ether the best; that of other makers was not always reliable, as had been found at the City Hospital. If one hand of the patient is held behind his back, he cannot get up during etherization.

Dr. BECKINGHAM always had the patient eat something one or two hours before taking the ether. Dr. GAY spoke of the advantage of always having an air space inside the cone, so that the ether should not touch the face. Among inhalers he considered Underwood's the best. In one case he had seen alarming collapse in a hearty man without apparent reason; has also seen it in cases of old impaired kidneys. It is always important in operations about the face to guard against blood getting into the trachea; also, great care should be used in cases of fluid in the chest. He uses opiates before etherization, for their stimulant and subsequent soothing effect. The stage of primary anaesthesia is good for small operations; the patient kicks, but does not feel the pain.

Dr. H. I. BOWDWIN urged the importance of avoiding ether in effusions in the chest.

Dr. A. T. CANOR said that in connection with Dr. Bowditch's remarks he would mention a case which occurred in his practice. A girl of about twenty, who had an empyema of three years' standing, was etherized for the purpose of establishing an opening with drainage. Her respiration was perfectly easy, at twenty to the minute, and her pulse, though rapid (120), was of fair character. Ether was administered by a skilful assistant, and when anaesthesia was sufficient the operation was begun by introducing an aspirator needle through the point selected for the opening. The patient winced somewhat at the entry of the needle. No pus was obtained.

While percussing the chest with the object of selecting a new point for operation the assistant said that the patient was in a poor state. She was pale and breathing badly. She was at once laid down and the pulse at the wrist was found to be imperceptible; in spite of ammonia applied to the nostrils and prolonged effort at artificial respiration, she did not rally. The difficulty seemed to be primarily in the heart. The autopsy made by Dr. Gannett showed the other lung in a fairly healthy condition; on the affected side (the left) there was no lung tissue proper, only a fibrous cake

at the top of the chest. The much-contracted pleural cavity contained about ten to twelve ounces of pus. The opinion that death was from heart failure seemed to be justified by the appearances on autopsy as well as by the symptoms. An examination of the ether bottle showed that only about two ounces had been used. Dr. Cabot said that his feeling at the time and since had been that syncope was induced by sitting the patient up to operate, aided somewhat by the nausea of a not very complete etherization and by the shock of the introduction of the needle, from which as was said the patient winced. Quite possibly a more complete etherization with its absence of nausea and shock and with its well-known stimulant effect would have prevented the disastrous consequences. The pulse and respiration of this patient were certainly no worse than in many cases successfully etherized.

Dr. FITZ said that post-mortem examination in one or two of these cases had led him to believe that the death was from heart failure, as it seemed to have been in Dr. Cabot's case.

Dr. BURRELL said he had noticed in a case of empyema that when complete anesthesia was established the pulse stopped, but began again when the ether was removed and the chest had been opened, allowing the pus to escape.

## SUFFOLK DISTRICT MEDICAL SOCIETY.

### SURGICAL SECTION.

S. J. MIXTER, SECRETARY.

JANUARY 7, 1885. Dr. J. W. ELLIOT reported FIVE SUCCESSFUL CASES OF OVARIOTOMY.<sup>1</sup>

Dr. LOMBARD inquired as to the relative value of short and long incisions.

Dr. ELLIOT said that the statistics of the most successful operations show that the short incision gives the best results. At the same time the incision should be long enough to allow sufficient room to work in.

In reply to questions by Dr. PORTER as to hemorrhage and the methods of controlling it, the reader stated that in one of the reported cases the ovarian artery was tied early in the operation; in the others the bleeding points were tied as they appeared. In many cases a temporary ligature may be placed about the pedicle. The case where the contents of the cyst escaped into the abdominal cavity did not do as well as the others. There were some spots of active peritonitis at the time of operation, and an abscess formed in the wound, as stated, which did not communicate with the abdominal cavity.

The reader objects to the use of drainage tubes. Great care is taken that the operation should be as aseptic as possible, and the abdomen is closed. Should trouble develop later the wound may be opened and a tube introduced. Ulzhausen recommends sewing up of the abdominal cavity without drainage, even when part of the cyst is left. This is, however, contrary to the general practice.

In reply to Dr. BURRELL, Dr. ELLIOT said that the principal point in the after-treatment is to let

the patient as much alone as possible. For the first twenty-four hours no food is allowed, then equal parts of boiled milk and lime-water are given in teaspoonful doses every hour. If this is borne, the quantity is gradually increased. Brandy is given by the rectum if the pulse is weak, and opium is given in the same manner if necessary.

Dr. E. W. CUSHING called the attention of the society to the use of purified naphthaline for cystitis with ammoniacal urine, as recommended by Rossbach, of Jena (*Berl. Klin. Woch. ft. No. 42, October 20, 1884*), also (*Berl. Klin. Woch. ft. No. 46, November 17, 1884*).

Dr. CUSHING reported a case of an elderly patient, who suffered from cystitis with intensely ammoniacal and foul urine, who had been treated with daily washing out of the bladder with carbolic solutions, etc. The naphthaline was tried as Rossbach recommends:—

R Naphthalini puriss.	55.	5.00
Sacch. alb.		
Ol. Bergamotte		.63
M. ft. pulv. No. XX.		

One powder every two hours to commence, each containing about four grains in wafers or capsules and simply mixed with water or flaxseed tea. On the second day the foul smell of the urine and of the room had disappeared, and it was thought to be due to the medicine, as during this time the washing out of the bladder was suspended. Afterward, however, local treatment of the bladder with boracic acid injections was combined with the naphthaline internally with the happiest results. Dr. CUSHING does not wish to draw conclusions from one case, but merely to suggest further trial of this drug.

In response to questions, he stated that naphthaline is one of the solid products of petroleum, and is insoluble in water, but soluble in naphtha, etc., and has already a high reputation as a destroyer of low organisms, being used in the museums at Cambridge, and elsewhere, to preserve specimens when painted over them.

Rossbach claims that, while not poisonous to man, it will act on bacteria, etc., in the intestinal cavity, and claims great results from its use in chronic intestinal catarrh, acute intestinal catarrh, cholera infantum, cholera nostras, typhoid fever, etc. Accidentally he noticed that the urine of patients under treatment was prevented from fermentation by some products formed in the body, which led him to try it in the cases of cystitis where the urine contained cocci and fermented in the bladder. Babo has some of the pure drug.

Dr. CUSHING inquired if any mechanical treatment had been attempted before the use of naphthaline.

Dr. CUSHING said that the regular treatment of cystitis in such cases had been tried without marked success, before the naphthaline was begun, and was then given up.

Dr. WALLACE PEEBLE reported a case of

### FOREIGN BODY IN ESOPHAGUS SUCCESSFULLY TREATED BY ANOMORPHIA.

A strong Irishwoman presented herself for treatment one hour after a hearty meal of mutton stew. Soon after the meal she vomited a little blood and felt a sharp pain in her throat especially

<sup>1</sup> See pages 99, 101.

with inspiration or swallowing. The examining finger in the fauces and the laryngoscope revealed nothing; but externally just behind the cricoid cartilage something could be felt to move and grate a little. The subcutaneous injection of apomorphia (grain one twentieth) caused vomiting in eight minutes, with the relief of all the symptoms and the removal with the vomitus of a piece of sheep's rib one and one-half inches long and half an inch wide, with very sharp ragged edges.

Dr. PORTER spoke of a case recently under his care in the hospital of a man who had swallowed five false teeth attached to a plate. They lodged in the œsophagus and could be felt, and were finally caught by winged probang such as is used for taking coins from the œsophagus, and drawn to the lower part of the pharynx, but before they could be seized with forceps they were again swallowed and could not again be felt. The patient was seen several times afterward, but he has at last accounts suffered no ill effects from the foreign body in the stomach or intestine.

Dr. A. T. CABOT spoke of a symptom that he had never seen mentioned in cases of foreign bodies in the œsophagus, observed by him in the case of a boy with a piece of tough beef impacted behind the cricoid cartilage. This symptom was flexion of the neck, any attempt to straighten it causing excruciating pain. After the fragment had been pushed on into the stomach by a probang, the symptom disappeared at once.

The Chairman, Dr. C. B. PORTER, reported a case of

#### COMPOUND FRACTURE OF THE LEG.

The patient, a man forty-five years of age, was run over by a milk-cart, September 21, 1881, sustaining a compound comminuted fracture of the right leg just above the ankle-joint, there being a short lacerated wound on the outside of the leg, at the seat of fracture. The patient was etherized and fifteen or twenty small fragments of bone were removed from the wound, and about an inch of the tibia was found to have been entirely destroyed. The tibia was cut down upon, the sharp ends of the fragments were sawn off and the fragments wired together with large silver wire. A drainage tube was passed through the leg behind the bones. After sewing up the wounds, they were dusted with iodoform and dressed with dry cotton-battings, and the leg put up in ham and side splints. The operation was performed under carbolic spray. On the following day the dressing was changed and a full Lister dressing was applied. This was changed at varying intervals, the wound doing uninterruptedly well, and the discharge being very small in amount. On November 8th, six weeks and five days after the operation, the wire was removed. The leg was in Lister dressing from September 21st to December 17th, twelve weeks and a half, the dressing being changed ten times. Between October 8th and 25th it remained without renewal. On January 2d the wounds had entirely healed, and the union being firm, all splints and dressings were omitted. Dr. Porter showed the patient and called attention to the very favorable result in a case where there was such extensive comminution.

### THE NEW YORK ACADEMY OF MEDICINE.

STATED meeting, January 15, 1885.

#### ANNUAL ELECTION OF OFFICERS.

The annual election of officers resulted as follows: President, Dr. A. Jacobi; Vice-President, Dr. C. C. Lee; Corresponding Secretary, Dr. L. Elsborg; Member of the Board of Trustees, Dr. A. L. Loomis; Member of the Committee on Admissions, Dr. A. S. Hunter; Member of the Committee on Medical Education, Dr. F. R. Sturgis; Member of the Committee on Ethics, Dr. Andrew H. Smith; Member of the Committee on Library, Dr. E. D. Hudson. The

#### ANNUAL REPORTS OF OFFICERS.

were read; and that of the treasurer of the Board of Trustees showed that during the past year \$1,880 had been contributed toward the liquidation of the mortgage on the building of the Academy. The report of the Library Committee showed the library now contains about 35,000 bound volumes and 9,000 pamphlets, and that during the past year there has been added to it 1,278 bound volumes and 1,875 pamphlets, in addition to 7,814 medical journals.

#### DEMONSTRATION OF KOCH'S CHOLERA BACILLI.

Dr. E. C. WENDT gave an exhibition under the microscope of cholera bacilli which he said had been sent to him by Dr. Robert Koch, of Berlin, and constituted the only authentic specimen now in this country, with the exception of one in the possession of Dr. Billings, of the United States Army. Under another microscope were exhibited specimens of the bacteria of the month, some of which Mr. Timothy Lewis, of the British Army, had claimed were apparently identical with the cholera bacilli of Koch. Although the latter microscope was of 800 smaller power than the former, Dr. Wendt thought there was no difficulty whatever in observing the marked differences between the two microbes.

Dr. W. D. SCHUYLER exhibited a

#### NEW OBSTETRIC FORCEPS AND VAGINAL SPECULUM.

The forceps are characterized by a well-marked pelvic curve, a somewhat short cephalic curve, and shanks that are shortened, closely approximated, and having a decided curve upward. It was claimed that they could be used with special advantage in cases of small ostium vaginae and of marked elevation of the perineum, such as are frequently met with in primiparae, and also in cases where it was not advisable to bring the patient to the edge of the bed. The speculum was a self-retaining one and consisted of a combination of Sims's, Thomas's, and Nott's specula. Both these instruments had been previously described in the *New York Medical Journal*.

Dr. FREDERICK A. CARTER said that the speculum now offered for sale as the Nott speculum was an entirely different instrument from that originally devised by the late Dr. Nott. It was his design that it should be used in the Sims position; but in order to adapt it for use while the patient was lying upon the back the instrument-makers had changed its character altogether.

DR. W. GILL WYLIE read a paper on

DISEASES OF THE FALLOPIAN TUBES: THEIR RELATIONS TO UTERINE DISPLACEMENTS AND THE USE OF PESSARIES.

Having alluded to the brilliant achievements of Lawson Tait in operations for the removal of diseased Fallopian tubes, he said that since May, 1883, he had himself operated in fourteen cases, nine of which were at Bellevue Hospital and five in private practice. Out of the fourteen patients two died: both of them being hospital cases and both dying of septicæmia on the fifth day. Eight of the cases were of pyosalpinx, two of hydrosalpinx, and four of catarrhal diseases of the tubes with peritoneal adhesions. With four exceptions, the ovaries were also diseased and attached to the tubes by adhesions.

An increased knowledge of disease of the tubes would, he thought, do much toward clearing up the subject of local peritonitis, which was often erroneously attributed in this country to cellulitis. Retroflexion and lateral versions of the uterus, with adhesions, were also frequently due to salpingitis. When such was the case, it could readily be understood how much injury might result from the use of pessaries under these circumstances. With the light thus thrown on the subject, the mechanical theory of uterine displacements, he believed, would sink into insignificance, and the space which had heretofore been given to it in the textbooks would in the future be devoted to a consideration of diseases of the Fallopian tubes, with their consequences and treatment. As to the ætiology of these affections, they are, as a rule, due to the extension of some pathological process from the lining membrane of the uterus to that of the tubes. In injuries salpingitis was comparatively rare.

Gonorrhœa was a frequent cause of such disease, and in stating his convictions on this point, a number of years ago, Dr. Noeggerath had been well in advance of the scientific thought of the profession. Whether Dr. Noeggerath had as yet succeeded in establishing the invariable presence of the gonococcus, he was not able to state. The sterility that was so common among prostitutes was accounted for by the frequent existence of salpingitis in this class of women. Other causes of salpingitis are syphilis and septic poisoning after abortion and labor at full term. It had been found that local peritonitis was much more common over the posterior surface of the broad ligaments than over the anterior, and this was because the Fallopian tubes opened upon the posterior surface. His experience, he said, led him to attach much more importance to localized peritonitis than to cellulitis, and while phlegmons are undoubtedly sometimes met with in the cellular tissue, he no longer believed in the existence of the so-called chronic cellulitis. Hysterocpilepsy and allied affections, Dr. Wylie thought, are always associated with degeneration of the ovaries accompanied with a catarrhal condition of the Fallopian tubes.

The subjective symptoms of salpingitis could not be distinguished, as a rule, from those of other diseased conditions of the pelvic organs. As to the objective symptoms, while they might not be under-

stood by an inexperienced observer, he thought the expert ought to have no difficulty in making them out if proper care were observed. It was his own practice to subject his patients to a prolonged course of preparatory treatment, consisting principally of applications of glycerine and alum; and when this had been done he believed that a positive diagnosis could almost always be made with ease. For our knowledge of the pathology of salpingitis, he continued, we had to depend entirely on the German writers, who had given a full and accurate account of it. As had been before remarked, the affection was almost always due to an extension of an inflammatory process from the endometrium to the tubes. The manifestations of this diseased action, however, differed in accordance with the difference of the parts in size, shape, and the character of the mucous membrane in each. Moreover, as the tubes could not be reached by local treatment, salpingitis almost always caused a greater or less amount of peritonitis, and almost always became chronic.

If it were supposed that the uterus were enlarged and bent backward, and that the tubes were involved in an inflammation extending from the endometrium, it could be seen how lymph pouring out from them into the peritoneum would be likely to produce attacks of peritonitis. As the process went on, the broad ligaments would become rolled up with the tubes, and the ovaries be firmly fixed in them. Under such circumstances the pain produced by pessaries warned us against their use; but if this was persisted in, there was great danger of causing thereby a rupture of the inflamed tubes, which were usually swollen and filled with infectious matter. Having spoken at further length of the surgical pathology, and the manner in which the displaced uterus became fixed as a consequence of the salpingitis, Dr. Wylie referred to the treatment in cases with adhesions, where operative interference was not permitted. Instead of attempting to keep the uterus in position by means of pessaries, he said he was satisfied if he could get it in a movable condition, as far as possible.

He had succeeded in tapping three cases. One of them was cured by this procedure; but he believed it was in reality a case of abscess which had formed in the site of an old hamatocœle. The other was benefited, but not cured, by the tapping; and the only cure for these cases he believed to be the complete removal of the ovary and tube on both sides. The concluding portion of the paper was devoted to the best methods of performing this operation. In opening the abdomen he believed it was important that a small incision should be made. It should not be larger than three fingers' breadth, which would allow the free use of two fingers in the wound; for if a larger opening was made, ventral hernia was liable to result, because the abdominal walls had not been previously distended, as was the case when there were larger tumors present. It was also important after the removal of the ovaries and tubes to secure perfect apposition of the deep fascia lata. It was his practice to feed his patients solely upon pancreatized milk for a few days before operating, as this had the effect of greatly diminishing the quantity of gas in the intestines and ren-

dering them so flaccid that they would not interfere with the operation. When the omentum was found to be in the way and held fast by adhesions, he advised that the operator should get two fingers underneath it in one of the fossae, when the adhesions could easily be separated. In order to get at the ovary with facility, it was advisable to elevate the uterus and unroll the convoluted broad ligament.

Dr. NOEGGERATH said that at the recent International Medical Congress in Copenhagen it had been clearly shown that the name "Tait's Operation" was a misnomer, since long before Tait had published his first cases, Hegar had reported (in September, 1879) no less than forty-two cases. Personally he was of the opinion that most cases of salpingitis are caused by gonorrhoea. He had for a long time been engaged in special studies to demonstrate the presence of gonococci, but had not, as yet, succeeded. The difficulty was that no gelatine had yet been found in which the gonococci could be raised. As to the relations between salpingitis and the inflammatory processes resulting therefrom and dislocations of the uterus, he believed that lateral versions combined with anteversion were the distinct form of displacement dependent on this disorder. Retroversion was met with in exceptional cases, in connection with pyosalpinx and hydrosalpinx; but in the great majority of cases of salpingitis, when the amount of exudation was not extreme, but the uterus was immovable, or only slightly movable, there would be found anteversion with slight lateral version. Retroversion with adhesions was rare in his experience.

It was not necessary to feel the tubes themselves in order to make a diagnosis; since peritonitis without salpingitis was extremely rare. The shape of the tumor, in cases where this could be made out was, however, of great importance. It was, as a rule, divided into three sections, conical in outline, and extending in the direction of the lateral diameter of the pelvis. As to the treatment, in the extreme cases nothing could be done except to resort to operation; but the large majority of cases were not ready for so radical a procedure, and something else had to be done for them. There was one kind of treatment which was much more successful than any other of which he was aware, and that was a sojourn at Franzensbad, in Bohemia; and he had seen a number of cases which had been practically cured by this, which for years had resisted all sorts of treatment both in this country and in Europe.

Dr. SKELNE, of Brooklyn, agreed with Dr. Noeggerath that it was a rare thing to see salpingitis unless it had been produced by gonorrhoea. On the other hand, he differed from Dr. Noeggerath in believing that perimetritis without any implication of the tubes was not at all rare. In the matter of diagnosis, he thought it was very difficult to distinguish between an enlarged tube, especially in the condition of hydrosalpinx, and a cystic ovary in Douglas's cul-de-sac. There was one point which had been overlooked, but which he thought might be of service in making a diagnosis, and that was aspiration. If ciliated epithelium was so common in pyosalpinx and hydrosalpinx as was represented, it was only necessary to draw off some fluid and examine it. Out of twenty-one specimens which

he had investigated, the epithelium was found in eighteen. This raised the question of treatment, and he believed that it was a fact that many cases had been operated on before other measures had been given a fair trial. This he believed to be due to a large extent to Tait's example and success; and he thought that operation should never be resorted to until more conservative means had been thoroughly tried. In pyo- and hydro-salpinx aspiration might perhaps result in a cure; the tube not refilling after the fluid had been withdrawn. Aspiration, therefore, he thought, might prove useful as a means of diagnosis and of treatment.

Dr. MUNDE said that he had paid special attention to the matter of diagnosis in salpingitis. He was, however, not yet satisfied on this point, and he thought that Dr. Wylie had failed to throw additional light upon it in his paper this evening. In the cases where it was most needed it was at present impossible to arrive at a positive diagnosis. In well-marked instances of pyo- and hydro-salpinx there was not this difficulty, and in such cases he had twice performed aspiration without the subsequent refilling of the tubal sac. The cases in which Dr. Wylie had operated seemed for the most part to be those of the kind in which there was diffuse thickening and infiltration in each broad ligament, with the occurrence of pain and a discharge of harmless matter at irregular intervals. In such cases he did not see how it was possible to make a positive diagnosis without resorting to laparotomy, and until we could perform this operation with the same success as Tait in England, he thought it was advisable not to attempt it. Under any circumstances, he did not think that gynecologists would perform laparotomy very often in this condition; and it was his firm conviction that we were only justified in resorting to it in those cases of salpingitis in which a sausage-shaped tumor was present and there was no room for doubt about the diagnosis. As to displacements in connection with salpingitis, he believed that retroversion was as common as anteversion; although he agreed with Dr. Noeggerath that in the majority of cases of retroversion the uterus was not bound down by adhesions. In speaking of the treatment, Dr. Mundé recommended the systematic use of the galvanic current, from which he said he had seen considerable benefit derived in quite a number of instances. It seemed to have the effect of reducing the diffuse swelling and relieving pain; but he did not think that cases of hydrosalpinx could be cured by this means.

Dr. WYLIE said that on account of the length of his paper he had omitted a considerable portion of it in the reading, and in the part omitted he had dwelt particularly on the assistance of preparatory treatment in enabling us to make a diagnosis. It was his practice to make applications of glycerine and alum on a thin pledget of cotton two or three times a week for at least six weeks, and sometimes for three months. Then, at the end of this course of preparatory treatment, he was in the habit of putting the patient under ether; when, the thickening of the tissues having been relieved by the glycerine and alum applications, there was usually no difficulty whatever in determining the exact size and shape of the Fallopian tubes. If Dr. Mundé would

adopt this plan, he felt convinced that he would not have the trouble in making the diagnosis, of which he had spoken.

But even if we did not feel positive that the tubes were diseased, there could be little doubt that the ovaries were in an abnormal condition; and he had rarely met with disease of these organs without accompanying disease of the tubes. In all the fourteen cases in which he had operated there was hardly one in which there was not more or less perimetritis. He therefore did not feel in doubt in regard to the diagnosis in these cases; and in all the more recent ones in which he had performed laparotomy he had been enabled to announce to his class the exact condition which would be found on opening the abdomen. As to aspiration, he had himself employed this, but not in the way that Dr. Skeene had suggested. The simple drawing off of the fluid would not, he believed, cure the patient, because in these cases of salpingitis a pyogenic membrane was formed, which would continue to cause accumulations. Diagnosis by aspiration had been proposed by Dr. Ferguson; but he thought it was safer to follow Tait's admonition: not to be tapping tumors upon which you were going to operate. The cases in which he had resorted to aspiration were those in which drainage was required. In the matter of displacements of the uterus in connection with salpingitis, his experience went to show that in women who had not borne children anteversion and lateral version were usually met with; while in others the salpingitis was nearly always associated with retroversion.

#### REPORT OF THE COMMITTEE ON MEDICAL EDUCATION ON A STATE BOARD OF EXAMINERS.

DR. C. C. LEE, chairman of the Committee on Medical Education, reported, in regard to a series of resolutions which had been referred to it at the last meeting, recommending that the Academy should urge the passage of a bill by the Legislature providing for the formation of a State Board of Examiners with power to grant licenses to practise medicine, that, in the opinion of the committee, it was inexpedient that the Academy should take such action at the present time.

#### MEETING OF THE AMERICAN SOCIETY OF PUBLIC ANALYSTS, JANUARY 12th, 1N BROOKLYN, N. Y.

A MEETING of the American Society of Public Analysts was held January 12th, with Dr. E. H. Bartley, of the Brooklyn Board of Health, in the chair.

DR. CYRUS EDSON, of the New York Health Board, spoke of the decomposition of gelatine used to adulterate currant jelly, and of the use of chemicals in the curing of meats and the preparation of head cheese and sausages. In the latter borax, boracic acid, saltpetre, and phosphate were employed to such an extent to prevent decomposition that there was often a full medicinal dose in each meal made on them.

The rest of the session was spent in discussing brewers' grains as a food for milch cows, and they were condemned as injurious on account of their

tendency to shorten the lives of the animals and their effect of making the milk thin, reducing the quantity of fat and sugar below the normal standard, and increasing the amount of casein.

DR. JOHN L. FINNEY, health officer of Port Richmond, stated that on account of the lupuline contained in these grains cows habitually fed upon them after a time get into the condition of persons addicted to the opium habit, and that the close confinement to which they are subjected added to the depression of their narcotism. In Orange County contracts for milk it was stipulated that grains should not be fed to the cows.

### Recent Literature.

*The Principles and Practice of Gynecology.* By THOMAS ADDIS EMMET, M.D. Third edition. Thoroughly revised. Philadelphia: Henry C. Lea's Son & Co. 1884.

We give a very hearty welcome to this book, for with so original a thinker and practical a worker as Dr. Emmet, four years in his life represents much that is new and of value to the profession. The work may now be said to fairly represent the present position of gynecology in America, and is one of the best, if not the best, that we have in the English language.

It has in this edition been "thoroughly revised, a great deal left out, and much new matter added." The author says in the preface: "The chapters on prolapse of the vaginal walls; on lacerations at the vaginal outlet, and through the sphincter ani and perineum; on the methods of partial and complete removal of the uterus for malignant disease; on the surgical treatment of fibrous tumors; on diseases of the Fallopian tubes, and on diseases of the urethra, are essentially new, containing the views and experience of the author in a form which has not been presented to the profession before."

Of these the chapter on prolapse of the posterior vaginal wall, in which the author describes the inside operation, by which the woman is saved much pain, and the after treatment is simplified, and that on diseases of the urethra, with the button-hole operations for affections of this canal, seem to us the most original and the most useful to the profession. While we have no doubt that the *rationale* of the first operation is perfectly clear to Dr. Emmet, yet we must confess to an inability to thoroughly understand the explanation of his views as to the function of the perineal body and its importance. The description of his operation, too, is not so clear and simple as we could wish; in fact, if there is any one criticism which we would apply to the whole book it is that of diffuseness and lack of simplicity. Many of the tables are complicated and unnecessary, showing a vast amount of work, we admit, but adding little that is valuable to our knowledge.

In spite of these minor defects it still remains a worthy exponent of a life devoted to the study and practice of gynecology; a book that will be of immense value to the profession at large, and one which will be a stimulus to better work wherever it is read.

F. H. D.

*A Textbook of Hygiene: A Comprehensive Treatise on the Principles and Practice of Preventive Medicine from an American Standpoint.* By GEORGE H. ROSE, M.D., Professor of Hygiene, etc. etc. Baltimore: Thomas & Evans. 1885. Pp. 324.

Dr. Rose has grouped together in this volume the various subjects comprised under the title of Hygiene. The arrangement of topics is convenient, and the general plan comprehensive. The subjects embraced in the chapters on Air, Water, Food, Soil, Removal of Sewage, Industrial Hygiene, and History of Epidemic Diseases, are fairly treated, while the important topics of Ventilation, Exercise and Training, Disinfectants, and Vital Statistics, would appear to have deserved a larger share of attention. The subject of ventilation especially is of sufficient importance to demand a separate chapter by itself.

While the author disarms criticism by saying in his preface that the volume contains but little new material, we cannot refrain from noticing certain obscure passages.

"The drainage of diluted sewage through a stratum of porous soil, not already saturated with putrefying matter, has no especially bad significance, even if the liquid should reach a well used as a source of drinking-water. It is probable that by the time the liquid portion of the sewage reached the well it would have arrived at that point when it could truthfully be termed pure water. At the same time it must be remembered that the purifying power of the soil cannot be relied upon if the supply of sewage or other animal or vegetable impurity is too abundant."

The adoption of any form of sewerage, either combined or separate, must depend largely on local conditions, hence the disposal of this question on pages 113 and 114 is too sweeping and arbitrary.

In alluding to the mode of propagation of vaccine virus, on page 261 the writer says:—

"Animal virus is obtained by vaccinating a calf or a heifer with vaccine virus, either derived from a case of small-pox or by reinoculating humanized virus into the animal." Query: Can that be called vaccine virus which is derived from a case of small-pox previous to its transmission through the heifer?

The entire absence of illustration is a notable feature of the work.

*The Brain and the Nerves: Their Ailments and Their Exhaustion.* By THOMAS STRETCH DOWSE, M.D., F.R.C.P.E. New York: G. P. Putnam's Sons. 1884. Pp. 150.

It is difficult to characterize this book. It is a combination of much that is excellent and of some weak statements with some extravagance in expression. The first chapter is headed "Of a few things which we do know, and of facts which have been established, in connection with the physiology and pathology of the nervous system, up to the present time." Very few "facts" are given; reflex action is explained rather obscurely; the function of "masses of gray and nervous matter, called central ganglia" is stated; a few words are said about "cerebrum or big brain, the cerebellum or little brain, and the spinal cord;" and a number of propositions given which the author says he will substantiate and which are not mentioned again.

The clinical descriptions are fairly good; several interesting cases are given. The author goes beyond most of us in saying "that every form of nervous disease and, as I would contend, every form of disease which is not nervous begins and takes its origin in nervous exhaustion." Making allowance for much irrelevant matter and some platitudes, which are probably not intended for professional readers, the chapter on treatment is not bad. It is scarcely necessary to tell a medical man, or others, that "Health means the bliss of man's mortal existence: disease entails discomfort, distress, wretchedness, premature decay, and death. Vice is the product of disease, and disease follows as the outcome of vice. A pure mind in a healthy body knows not vice. Man's responsibility and morality must be based upon the healthy state of both mind and body." Part of this is trite and part is not true.

The remarks about drugs are, on the whole, good. He values quinine, arsenic, and zinc highly; iron, cannabis indicæ, chloral, and phosphorus do not find favor with Dr. Dowse. Of the bromides, he says:

"They substantiate the *ego*, and give moral courage by establishing a balance of power between the volitional and automatic nerve centres." He says, he has "arrested cases of advanced consumption" with opium, "which appeared, and which were in fact progressing by rapid strides to death, when other remedies were absolutely useless."

Dr. Dowse is a firm believer in the moderate use of alcohol, as a common necessary of life, but condemns its excessive use. His picture of the total abstinence is gloomy: he "is frequently a grumpy, growling, cadaverous, ill-tempered, shriveled specimen of humanity, who is always dyspeptic, despondent, flatulent, and careworn, not like a man who was sent into this world to enjoy in due season the fruits of the earth." Perhaps the author had received a temperance lecture just before writing and his irritation had scarcely subsided.

The remarks about diet are rather unsatisfactory: about three fourths could have been omitted with advantage, and more attention have been given to the best methods of feeding patients. Under electricity, Ohm's law is stated, and the reader thinks useful information is about to be given, but on turning the page disappointment awaits the seeker for knowledge—Ohm's law is dropped. The author's statements as to travel, massage, mental recreation, and persistence of treatment are good.

We have only briefly mentioned some of the excellencies of the volume, not because there is not much to be commended; but the absurdities and unsatisfactory observations are so many they have absorbed all our time. There is a decided lack of uniformity, some parts are good, others are trash.

S. G. W.

*Handbook of the Diagnosis and Treatment of Skin Diseases.* By ARTHUR VAN HARKLING, M.D. Philadelphia: P. Blakiston, Son & Co. 1884.

This is an excellent little book of 282 pages in which for ease of reference the more common diseases of the skin are arranged in alphabetical order, while many good prescriptions are given, together with clear and sensible directions as to their proper application.

**Medical and Surgical Journal.**

THURSDAY, JANUARY 29, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by CUPPLES, UPHAM & CO., Boston. Price, 15 cents a number; \$5.00 a year, including postage.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUPPLES, UPHAM AND COMPANY,  
283 WASHINGTON STREET, BOSTON, MASS.

**INSANE CRIMINALS.**

A SHORT TIME ago one of our daily newspapers stated there was under consideration the establishment of a hospital for insane convicts, in connection with the new reformatory prison for men at Concord, Massachusetts. The article in question went on to say that prisoners became insane in our penal institutions and were then necessarily removed to the State Insane hospitals. Of persons so removed there were now about one hundred, a number sufficiently large to demand some separate plan of treatment, especially in view of the fact that the ordinary insane are brought into close daily contact with them.

The yard connected with the reformatory is large enough, it is said, to allow of the erection of a brick building for the insane criminals in its south-west corner. A small yard could be set off and even if they should stray into the larger and adjoining yard, they could be watched by the guard on the wall, in the same manner the other prisoners now are."

For several years, as those of our readers who are interested in the matter will remember, we have called attention to the necessity of separate provision for insane criminals. We have urged this plan as being the best adapted to the care of this class of the insane. Mixed treatment with either the ordinary insane or sane criminals brings them at once under conditions unfavorable to recovery. In this view we are unanimously upheld by insane hospital superintendents, who have practically felt the disadvantages of associated treatment, and speak with authority.

We do not believe that a hospital for insane criminals would be well situated within the walls of the reformatory. Against such an arrangement is the history of the Asylum for Insane Criminals at Auburn, New York. This building is outside of the prison walls proper, but in its early days was reached through a gate in the wall. Such close proximity was found to be seriously demoralizing to the asylum, and the gateway was eventually closed, but even then the prison methods of discipline and moral treatment of prisoners prevailed at the asy-

lum, and made it more of a department of the prison than a hospital. Thorough reorganization of the asylum, under difficulties, has brought it up to the proper standard of a medical institution for the insane, but under inefficient management it would easily retrograde and become again a prison department.

For several years the superintendent of the Auburn asylum, in his annual reports, has urged the removal of the institution into the country, both for the purpose of escaping the demoralizing atmosphere, almost unconsciously emanating from the prison, and also to obtain a large farm on which the patients could labor unrestrictedly.

It would be practically impossible to have the insane criminals straying out of their own enclosure into the main yard of the prison and there watched by guards, as suggested in the above newspaper paragraph. Such a plan would bring them into contact with the convicts, and subject them to prison rules, and, as a member of the Board of Prison Commissioners said to the writer a day or two ago, interfere with the proper arrangement of the yard, which should be kept clear, that the guards might be able to watch, and, if necessary, shoot at, escaping prisoners.

The only plan at all feasible in connection with the reformatory would be a separate hospital some distance away on the land owned by the State. This hospital should be absolutely controlled by a medical superintendent, who could easily attend to the medical work at the reformatory. Some kinds of special work at the hospital could be performed by the convicts, such as helping painters, carpenters, plumbers, etc. And it is probable that the first cost of building could be lessened by employing convict labor. In addition, the cost of the land would be saved to the State.

It would seem at first sight that economy might be further practised by such nearness to the reformatory, as, for instance, in the use of one laundry, bakery, barn, etc., and the buying of stores and provisions. We would not deny that such might be the case, but the history of the Auburn asylum has clearly demonstrated that the less it has had to do with the prison the better hospital it has become, and we very much doubt if, in the long run, the conjoint plan of management would result in any appreciable saving of money.

**A MILITIA AMBULANCE CORPS FOR MASSACHUSETTS.**

ANY ONE who reads the annual report of the Surgeon-General of Massachusetts for the past year cannot fail to be struck by its progressive character. It is the desire of the medical commandant to render the part of the militia service under his charge ready for all emergencies. For he reports that the

medical department of the several commands is now fairly well equipped with the instruments and appliances, in a good and serviceable condition. necessary for active service should the troops be called upon for such duty. But the presence of medical officers with proper appliances does not, by any means, supply all that is needed for the care of sick and disabled, and the Surgeon-General calls attention to the necessity of men who shall be especially instructed in the proper handling and transportation of the sick and wounded. No more humane and important change in the organization of armies has been made in late years than that relating to the care and transportation of the sick and wounded, and during the late war no more important or better work was done in any department than that known as the ambulance corps.

A militia force should be a miniature army, perfect in all its appointments and departments. No addition or change that could be made in our military force would add so much to its efficiency, or serve so well to elevate it to a still higher standard than it now enjoys, as the enlistment and organization of such a body of men. The Surgeon-General, therefore, recommends that such a corps be organized for each brigade, these men and their officers to be known as the Ambulance Corps of the Militia of Massachusetts. In case of riot or other active service, such a corps would be of the greatest value, both by reason of doing the work for which they are to be organized much better than men untrained in this specialty, and in saving for other service men who would of necessity be taken for this duty.

If our militia are to be worth anything, they need to be ready for active service at a moment's notice. Active service means the possibility of wounds, and no militiaman will be less willing to do his duty for knowing that every provision is made beforehand for his cure if he is so unfortunate as to suffer in the performance of that duty. Our own opinion of the desirability of such a corps was expressed in these columns not very long ago, and we hope that the Surgeon-General's recommendation will be favorably received.

#### A PAID SERVICE IN THE NEW YORK DISPENSARY.

THE New York Dispensary, the oldest dispensary in that city, is about to change entirely its system of medical administration. In place of the thirty-two attending physicians and surgeons, who serve an hour or more three times a week, five medical officers are to be appointed after a severe competitive examination, to serve four hours daily, except on Sundays and holidays, when but one hour's service is to be required. The new appointees are to

receive eight hundred dollars per annum, and one of them, the Physician-in-chief, or House Physician, twelve hundred.

The examination was to have taken place yesterday. According to the stipulations announced, candidates must have served a term in some general or special hospital. Nearly forty applications had been received. The medical committee having charge of the new order of things, consists of Drs. T. A. McBride, S. Oakley Van Der Poel, G. G. Wheelock, G. L. Peabody, and W. T. Bull.

When this change is effected, all branches of this Dispensary service will be administered by salaried officers. The District Physician, an Italian practitioner, and four trained nurses have been in receipt of salaries for a year past.

Hitherto the medical services of the free dispensaries in our cities have been unremunerated, except by the experience gained by devotion to the work. The effects of this change of system at the New York Dispensary will be watched with interest. There is certainly much to be said in favor of the step which its managers have thought it best to take. There is absolutely no danger at present of over lucrative offices, or sinecures of any kind, being created for medical men; and least of all for the younger toilers in our hard-worked profession.

#### THE GERM THEORY OF DISEASE.

EVERY ONE who has intelligently noted the labors of the past twenty years, in all lands, by indefatigable workers, in the domain of mycology and microscopy, labors conducted with elaborate culture, apparatus and chemical appliances, and costly experimentation, and performed with one great end in view—to ascertain the causes of certain communicable diseases,—must have passed through a stage of scepticism to a firm persuasion that progress has been made, and that a clew has been found to many of nature's profoundest mysteries. The number of those who are in sympathy with investigations of this sort is, we venture to say, becoming greater every day, and yet there are some who still talk slightly and sneeringly of these undertakings—as did an honorable and influential member at a district medical meeting last week—as though the germ theory of disease were “an unfounded hypothesis,” a “visionary and fanciful theory,” devoid of any useful therapeutical outcome, and sure to continue to be unproductive of any valuable practical results.

Prenising that a “theory” may be well founded or ill founded, and that hypotheses are sometimes of great use, we would here remark that only so far as the practice of medicine is based on correct views of causation can it be anything but empiricism, and if any one thing is clear it is that the drift of scientific therapeutical endeavor must be far away from

empiricism to treatment founded on known laws — the goal may be distant and difficult of attainment but the struggle toward it will ever go on.

In regard to the origin of the specific infectious diseases — and by infectious maladies we understand all diseases communicable from individual to individual — there can be but two theories entertained at the present day: either the morbid process is of the nature of a chemical fermentation, or we have ætiologically to do with a *contagium vivum*. The arguments which compel acceptance of this alternative position are so well stated by Liebermeister, in Ziemssen, that we need not reproduce them here. But the labors, the past thirty years, of Cagniard de la Tour, of Hchuholtz, of Schroeder, and Dusch, finally, of Pasteur, have shown that fermentation and putrefaction are dependent on the presence of certain microorganisms, so that, as Liebermeister observes, the theory of fermentation becomes virtually identical with the theory of a *contagium vivum*.<sup>1</sup> The study then of the phenomena of organic decomposition irresistibly suggests conclusions which are in harmony with the fundamental biological ideas of the age: the struggle for existence which characterizes all animate nature; the strict dependence of all organisms on their environment; the lower life everywhere pervading the higher, competing with it for the means of subsistence — where it can overcome the higher life — doing so, and multiplying prodigiously and destroying without stint where the conditions are favorable for development and pollution.

The analogical argument from which the conclusion is drawn that all the human infectious diseases are due to a living ferment is very strong. The epidemic and contagious diseases of plants and the lower animals, as far as studied, countenance no other view; in fact, in numberless instances the specific morbid fungus has been found, isolated, cultivated in a proper medium — an infinitesimal product of one culture has been used to start another culture in a sterilized medium, and so on for many successive generations, and with a minute portion of the final culture healthy organisms of the same or of different species have been inoculated, and the original disease has been reproduced. By proof of this kind, Pasteur showed that the epizootic known as Pebrine, so prevalent among silkworms, is the result of the ravages of a microbe discovered by Filippi, and called by Lebert, *panhistophyton*. Another infectious disease, chicken cholera, has been shown to originate in the depredations of a little micrococcus, which is easily cultivated, with entire preservation of its virulent properties, in chicken broth, made alkaline by potassa, but which dies when sown in yeast, although the anthrax bacillus lives well in the latter medium, an illustration of the fact that microbes do

not thrive in all nutrient media, and that a favorable environment is necessary according to the great law appertaining to all living beings and formulated by Lamarck and Charles Darwin. It is hardly necessary to refer to the fact that the grape-vine disease (phylloxera), the ergot of grain, the potato disease, have been proved to be caused by microscopic fungi.

The investigations in this country of Salmon and Detmers have conclusively shown that swine plague and the Texas cattle fever are of bacterial origin.<sup>2</sup>

Salmon has made many interesting experiments confirmatory of Pasteur's discovery of the microphytic origin of fowl cholera, and justly observes, with reference to the power of propagation of infinitesimal portions of contagium: "Formless ferments are unable to reproduce themselves. Reproduction and multiplication is a function of living matter, and of this alone, and when we have proved that virus can be cultivated indefinitely it is equivalent to demonstrating that its essential constituent is a living thing."<sup>3</sup>

Among the communicable diseases which prevail among the lower animals is one which is also common to man, though always derived from the diseased animal: we refer to anthrax, also known as splenic fever, charbon, wool-sorter's disease, malignant pustule. This disease, endemic in some parts of Europe, has been observed in this country. Its ravages among cattle and sheep have been very great; in one Russian district alone there perished in the course of three years 56,000 domestic animals — horses, cows, and sheep — and 528 human beings.<sup>4</sup> Severe constitutional symptoms of a typhoid character attend the development of this malady, which may almost be looked upon as the type of acute contagious diseases.

Writers (as Belfield<sup>5</sup>) have insisted on the fact that this so-called "wool-sorter's disease" occurs both sporadically and epidemically; that it is limited to certain conditions of soil and of climate; that it is especially prevalent during certain seasons of the year; they have referred to the predisposing influence of heat and moisture, the stage of incubation, the self-limitation of the affection, and its non-recurrence.

The attempts which have been made these late years by careful, conscientious, and indefatigable workers, such as Pasteur, Toussaint, Greenfield, and Robert Koch, to ascertain the hidden cause of this disease have been followed by results as gratifying as they are surprising. Not only has the bacterial origin of anthrax been proved beyond the possibility of cavil, so that all authorities worthy of any respect admit it, but the specific microbe, the *bacillus anthracis*, has been found and cultivated, and with

<sup>1</sup> See Reports, Dep. Agriculture, 1880-82.

<sup>2</sup> Report of the Commissioner of Agriculture, 1881-82.

<sup>3</sup> Belfield, Cortwright Lectures, 1883.

<sup>4</sup> Loc. cit., Lecture III.

<sup>5</sup> Ziemssen's Cyclopædia, vol. I, page 10.

the fungous product of long series of cultures the disease has been reproduced at will. Nay, more, a "protective attenuated virus" has been obtained by suitable cultures, and with this Pasteur believes he has saved the flocks of Europe by the hundreds of thousands.

The inference is almost irresistible that if anthrax be of bacillary origin, the other malignant infectious diseases are equally so, but we are warned that it will not do to press the analogical argument too far, or to make too large inductions from the facts already in our possession. We have a right to conclude from the data already acquired respecting anthrax that all cases of this disease, wherever occurring, are bacillary, but we are not justified from these data in affirming that the bacterial nature of the *materies morbi* of typhoid fever, diphtheria, scarlatina, etc., is proved. We can only say that such conclusion is very probable, in fact more probable in the present state of science than any other. But for each specific disease the problem of causation must be worked out independently, as has been done for anthrax.

It is needless to say that the work is being pushed with vigor, and that what has been done for anthrax has been—with great apparent success, confirmation by other experimenters being waited for—accomplished the past year for diphtheria by Loeffler, and for ordinary pneumonia by Talamon and Friedlander. It has, in fact, been rendered almost certain by these latter experimenters that pneumonia is an infectious disease, occasioned by the presence in the blood and tissues of the lungs of an oval wheat-shaped micrococcus; cultures have been made of this bacterium, and inoculations practised on animals with the remote product of the culture, and the original disease with all its characteristic symptoms and lesions has been reproduced.

We have thus far said nothing respecting Obermeier's spirillum of relapsing fever, or Koch's discoveries as to the aetiology of tuberculosis. They both have been sufficiently referred to in former numbers of this Journal, and if *admitted* (as they certainly are by the great body of pathologists all over the world), they must be considered as giving increased probability to the germ theory of all other communicable diseases.

Nor have we touched upon the inevitable bearing of these new views of causation on therapeutics. This we propose to do in a future number.

#### MEDICAL NOTES.

—The theory and practice of politics, and the necessity imposed by that science of delicacy in shading between matters of right and wrong, develops in the minds of those who habitually devote themselves to such pursuits a facility in the drawing of subtle distinctions which causes admiration

in the uninitiated. We read, for instance, in an esteemed contemporary of the daily press of an accident which befel a prominent citizen of Boston, whereby "both bones in the lower portion of his leg were broken clear off, but, fortunately, without any fracture of either of the bones, so that the process of healing will probably be rapid." The curiosity of plain professional minds is excited to know what would have been the effect upon this gentleman if the bones had both been fractured but not broken, or in case one had been fractured and the other broken. The application of the transcendental methods of newspaper political writing to medical matters has before now caused confusion in the public apprehension, and we affectionately implore our brethren of the political press to guard against a careless handling of their sharp weapons.

#### PORTLAND.

—Abner Coburn, ex-governor of Maine, recently died in his eighty-second year, leaving property which is estimated by some to be worth eight millions. He bequeathed to the Maine General Hospital one hundred thousand dollars, the largest gift by far which it has ever received.

#### NEW YORK.

—That the small boy of the streets is willing to run his chances of death by poison from condemned candy was clearly shown by an incident which occurred the other day on the east side of the town. Between 7,000 and 8,000 pounds of candy toys colored with vermilion, chrome yellow, chrome green, and even Paris green (those with leaves), had been seized and were being dumped into a trench by the sanitary officers, when it became noised about the neighborhood what was going on; and soon there was gathered an enormous crowd of urchins, who made such a desperate attack upon the load of candies that it became necessary to call in the assistance of a section of policemen from a neighboring station-house before they could be driven back.

—Dr. Ludwig Senff, resident physician of the Montefiore Home, died at Mount Sinai Hospital, December 14th, of chronic Bright's disease. He was born at Schievelbrin, Germany, in 1832, and studied medicine in Berlin. He afterward became a surgeon in the army and served with distinction during the last three Prussian wars, for which he was decorated by the emperor with the Iron Cross. In 1879 he left the army and went to London, where he remained until about six months ago, when he came to New York. When the Montefiore Home for chronic invalids was opened in October, he was appointed resident physician. Dr. Senff was a widower, and leaves two daughters in London and two sons in Berlin.

## Correspondence.

## THE LATE DR. W. H. THORNDIKE'S SURGICAL SKILL.

BOSTON, January 17, 1885.

MR. EDITOR, — In the interesting obituary notice of the late Dr. Thorndike, published in the *JOURNAL* of January 15th, a few of the triumphs of this remarkable surgeon were mentioned. One, however, was omitted which deserves to be added to the record. It was the removal of a fibroid tumor from the walls of the stomach. The stomach was laid bare by laparotomy, and the tumor being found adherent was dissected off from the peritoneal layer of the stomach. Recovery from the immediate effects of the operation was good; death, however, took place three weeks later from some accidental cause. The operation was performed many years ago, before gastrotomy and gastrostomy had become firmly established as surgical procedures.

Very truly yours,

E. H. B.

## ACTINOMYCOSIS IN CHICAGO.

125 State Street, CHICAGO.

MR. EDITOR, — I am quite sure that the *Boston Medical and Surgical Journal* never intentionally allows any individual to be misrepresented, nor does it knowingly admit the misrepresentation of facts pertaining to medicine. The difficulties pertaining to medicine are great enough even when the student is an eye-witness of the facts obtainable from nature; the difficulty becomes immeasurably greater when they are reported second and third hand. To render this difficulty as small as possible, the indispensable requisition of any reporter is simple *veracity*. It makes no difference whether the lack of veracity arises from ignorance, negligence, or wilfulness. The result, as far as the difficulty associated with the appreciation of the facts is concerned, is the same. Allow me to inform your readers that your Chicago correspondent, in the issue of January 1st, has, from some cause, ignored in a remarkable manner this sterling virtue. I will illustrate this by referring to the closing sentence of his correspondence: "Next Dr. Murphy reads a careful report of his cases before the Medical Society, and exhibits his specimens."

Dr. Murphy not only did not exhibit "*specimens*," but he did not exhibit a single specimen. He or some one else brought one specimen; but Dr. Murphy was obliged to apologize for not exhibiting it, giving as a reason that the glycerine had leaked out, and nothing was visible. Dr. Bellfield exhibited a specimen, but that was from a bovine case, as he himself stated.

As to whether the editor of the *Medical Review*, your humble servant, quoted "*ad nauseam*" paragraphs from the public press, which he distinctly stated were quoted as more likely to be efficient than any exhortation to show the profession what should be avoided, is a matter of taste, and depends somewhat on which side of the fence the individual happens to be.

As to the implied supposition that it is imperi-

ment to dissent from the opinion of a good pathologist, the subscriber claims the birthright, and even essential quality, of every physician, namely, the right to form his own opinion. The most charitable view that can be taken of the question is that your correspondent was not present at the Medical Society when the cases were presented.

A fair discussion of the presentation, if the editor is capable of discussing a question fairly, was given in the issue of the twenty-seventh of December, 1884, of the *Chicago Medical Review*.

R. TILLEY, M.D.

## LETTER FROM THE ADIRONDACKS.

JANUARY, 1885.

MR. EDITOR, — A recent hasty trip to the Adirondacks has interested me in the colony of consumptives located at Lake Saranac, and I trust the information I obtained will be welcome to your readers. A few words from one who has obtained recent experience of a little-known health resort may sometimes furnish just the information needed by some invalid or his medical adviser.

Saranac Lake is a township of some five hundred inhabitants, situated in the Northern Adirondacks, about half way between Lake Placid and Paul Smith's. It lies at an elevation of about twelve hundred feet above the sea-level, in the valley of the Saranac River, an insignificant little stream emptying into Lake Champlain, and is noted for a uniform winter climate, very cold to be sure, but clear and dry and bracing. The township extends far into the country, but the village itself is quite small. The houses and stores are nearly all upon one narrow street that runs parallel to the river, and the public buildings consist of a church and a library. It is simply a quiet mountain town. In this little village collects each fall a colony of invalids and their families, numbering some fifty or sixty in all, who pass the winter in this very retired place.

It is well known what the friends of the Adirondack region claim for its influence upon pulmonary troubles. In many cases of phthisis a winter in the mountains, as well as one or more summers, forms the plan of treatment. It is this fact that accounts for the presence of the little winter colony. These invalids lead very largely an out-of-door life. They drive morning and afternoon without regard to the weather, except to wrap themselves up very thoroughly. They all wear buffalo coats, fur caps and hoods, and felt boots; well wrapped up in furs they will take a sleigh-ride of ten or fifteen miles when the thermometer is twenty or thirty below zero. Even people in the later stages of phthisis experience no discomfort or bad after effects from this, and taking cold seems to be unknown. They walk out when possible, go to bed very early, and lead in every way a very healthful sort of life, except for the depressing effects of association with so many invalids. The results of such a winter regimen are said to be excellent.

But the place is very inaccessible; it lies thirty-five miles from the railroad at Ausable, and fifty miles from the main line at Port Kent. The stage-ride from either place to Saranac is over a rough plank road; it is long and tiresome, and for the

most part uninteresting. It takes a whole day to accomplish it, and in winter the stage accommodations are very poor, although there is one stage each way daily. All this, of course, makes the price of provisions very high. Board is from fifteen to thirty dollars a week, and there are only one or two good boarding-places in the village. Some people are able to hire houses of the natives for the winter, but such a plan is very costly, and out of the reach of the majority of people. In any way the place is a very expensive one to live in, and therefore not available to other than well-to-do people.

About a mile outside of Saranac village there stands on a hillside, some two or three hundred feet above the road, a group of new buildings known as the Sanitarium. The object of this little charity is to furnish a place where people of the middle classes, clerks, shop-girls, mechanics, and the like, can have the benefit of the Adirondack air and life at a moderate rate of board which shall be far below the very high rates charged in the boarding-houses and hotels. The situation of the place is superb. It stands on a spur that runs out to the east; protected upon all sides but the south by mountains, it lies open to the sun all day long. A magnificent view stretches off to the south, and the mountains that lie around are quite respectably covered with timber, as Adirondack mountains go. A wooden house of some ten or twelve rooms forms the centre of this group of buildings. It is intended for the matron's quarters, the dining-room, and the bed-rooms of the sicker patients. Near this are two or three little cottages, standing apart, containing only one room each, in each of which two patients are to sleep, who will take their meals at the central building. It is hard to imagine what an attractive little group of buildings the Sanitarium forms. The central house is painted dark red, and has a gable roof, with piazzas here and there, and sunny little rooms with open fireplaces. The cottages stand around only a rod or two away, cheap little affairs to be sure, but neat and comfortable. The whole atmosphere of the place is bright and cheerful.

The institution is not intended to be self-supporting. It is proposed to charge each patient three dollars a week for board and medicine, which, of course, falls far below the real cost. The remaining expense must be made up for by the contributions of charitably disposed people. A small farm is to be managed in connection with the place, which will furnish out-of-door work to the men in summer, and the women are expected to help in the necessary work of the house. For it is not intended for cases of advanced phthisis, nor will such be received, but for the cases of beginning pulmonary trouble which are so likely to be benefited by a change to this sort of life. Dr. Loomis, of New York, is to be the consulting physician, and applicants for admission must obtain a certificate of fitness from him or from Dr. Trudeau, of Saranac, the attending physician.

The accommodations at first are to be limited to ten or twelve patients; later it is hoped to extend the accommodations of the place by building more cottages as the funds are at hand. It is to be opened in February.

This charity, like everything else in Saranac, is unique. The whole life of the place is unconventional and peculiar; to an outsider it seems particularly delightful and unlike American life elsewhere, and even to the invalids exiled there the quiet out-of-door life, although to a degree monotonous, is particularly acceptable and congenial.

Very truly yours,

ROBERT W. LOVETT.

## Miscellany.

### THE INDEX MEDICUS DISCONTINUED.

THE following notice, we are sorry to say, addressed to the subscribers to the *Index Medicus*, accompanies the Annual Index which completes the sixth volume of that publication:—

#### NOTICE.

With this issue, containing the title-page and annual index of Volume VI, the *Index Medicus* will cease to be published.

During its six years' career it has been supported by its special friends with a generosity perhaps unparalleled in the history of medical journalism. The publisher, the late Mr. Leypoldt, notwithstanding a heavy loss at the outset, and a but slowly diminishing annual deficit, maintained the undertaking with characteristic spirit and zeal. His successors, who are managing his estate and business enterprises, have made strenuous efforts to place the *Index Medicus* on a self-supporting basis, remembering with what particular favor Mr. Leypoldt regarded it.

Their latest effort has been unsuccessful, and the few additional subscriptions which were required have not been obtained.

The time has come, therefore, when neither zealous friends nor generous publishers can be allowed to make further efforts or sacrifices, and the publication is discontinued.

Whether it will in some other shape, or under some other auspices, again appear, is for the future to decide.

JOHN S. BILLINGS,

ROBERT FLETCHER, Editors.

### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE. OCTOBER 1, 1884, TO DECEMBER 31, 1884.

BAILLACHE, P. H., surgeon. Granted leave of absence for thirty days. October 9, 1884.

To proceed to Wilmington, N. C., as inspector. November 10, 1884.

Relieved from duty as chief of purveying division; to proceed to Philadelphia, Pa., and assume charge of the service, December 10, 1884.

WYMAN, WALTER, surgeon. Granted leave of absence for fifteen days. October 15, 1884.

Leave of absence for fifteen days in December, 1884, and thirty days in January, 1885, also for a further period from January 31, 1885, without pay, and with permission to visit Europe. December 8, 1884.

PURVIANCE, GEORGE, surgeon. When relieved to proceed to Cincinnati, Ohio, and assume charge. November 12, 1884.

To Louisville, Ky., as inspector. November 21, 1884.

AUSTIN, H. W., surgeon. To proceed to Boston, Mass., and assume charge. November 12, 1884.

SMITH, HENRY, surgeon. When relieved to proceed to Cairo, Ill., and assume charge. November 9, 1884.

Granted leave of absence until January 15, 1885. December 17, 1884.

STOXER, G. W., passed assistant surgeon. Relieved from duty at Delaware Breakwater Quarantine, to proceed to Cairo, Ill., in accordance with former orders. October 14, 1884.

To Norfolk, Va. November 19, 1884.

IRWIN, FREDERICK, passed assistant surgeon. To close Cape Charles Quarantine October 31, 1884, to proceed to Washington, and to report to Surgeon-General. October 14, 1884.

To take charge of the service, port of Georgetown, D. C., and detailed as acting chief clerk, Surgeon-General's office. October 30, 1884.

To Philadelphia, Pa., and Baltimore, Md., as inspector. December 20, 1884.

MEAD, F. W., passed assistant surgeon. When relieved to proceed to Baltimore, Md., and assume temporary charge. December 10, 1884.

HEATH, W. H., passed assistant surgeon. Granted leave of absence for thirty days on account of sickness. October 24, 1884. When relieved to proceed to Pittsburgh, Pa., and assume charge. December 26, 1884.

GUIERAS, JOHN, passed assistant surgeon. To report to Surgeon-General. November 8, 1884. Leave of absence extended fifteen days, without pay. November 14, 1884.

WHEELER, W. A., passed assistant surgeon. Relieved at Chicago, Illinois, to proceed to Buffalo, N. Y., and assume charge. December 26, 1884.

BANKS, C. E., passed assistant surgeon. When relieved, detailed for special duty; upon completion of same, to Boston, Mass., for duty. October 28, 1884.

PECKHAM, C. T., passed assistant surgeon. Granted leave of absence for twenty days. December 26, 1884.

BENNETT, P. H., assistant surgeon. When relieved to rejoin his station (Detroit). November 20, 1884.

AMES, R. P. M., assistant surgeon. To report to Surgeon Hutton, at Louisville, Ky., for examination for promotion. November 13, 1884.

DEVAN, S. C., assistant surgeon. To proceed to Tacoma, W. T., as inspector. October 14, 1884.

KALLOCH, P. C., assistant surgeon. Granted leave of absence for thirty days. November 19, 1884.

GLENNAN, A. H., assistant surgeon. To proceed to Key West, Fla., for temporary duty. October 8, 1884.

BATTLE, K. F., assistant surgeon. Granted leave of absence for thirty days on account of physical disability. December 6, 1884.

BROOKS, S. D., assistant surgeon. To proceed to New York, N. Y., for temporary duty. October 20 and November 26, 1884.

WHITE, J. H., assistant surgeon. To proceed to New Orleans, La., for temporary duty. October 3, 1884.

To escort insane seaman to Government Hospital for the Insane. December 17, 1884.

Granted leave of absence for fifteen days. December 23, 1884.

## RESIGNATION.

SMITH, HENRY, surgeon. Resignation accepted by the Secretary of the Treasury, to take effect January 15, 1885. December 17, 1884.

## APPOINTMENT.

WHITE, JOSEPH H., M.D., of Georgia, having passed the examination required by the Regulations, was appointed an assistant surgeon by the Secretary of the Treasury, October 2, 1884.

## PROMOTIONS.

PECKHAM, C. T., passed assistant surgeon. Promoted and appointed passed assistant surgeon by the Secretary of the Treasury from December 1, 1884. November 28, 1884.

AMES, R. P. M., passed assistant surgeon. Promoted and appointed passed assistant surgeon by the Secretary of the Treasury from December 1, 1884. November 28, 1884.

DEVAN, S. C., passed assistant surgeon. Promoted and appointed passed assistant surgeon by the Secretary of the Treasury from December 1, 1884. December 5, 1884.

URQUHART, F. M., passed assistant surgeon. Promoted and appointed passed assistant surgeon by the Secretary of the Treasury from December 1, 1884. December 5, 1884.

## OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JANUARY 17, 1885, TO JANUARY 23, 1885.

TREMAINE, W. S., major and surgeon. Granted leave of absence for one year on surgeon's certificate of disability. S. O. 14, A. G. O., January 17, 1885.

MAXS, LOUIS M., captain and assistant surgeon. Granted leave of absence for two months on surgeon's certificate of disability, with permission to leave the Division of the Missouri. S. O. 16, A. G. O., January 20, 1885.

STEPHENSON, W.M., first lieutenant and assistant surgeon. Relieved from duty at Fort Omaha, Neb., and ordered to Fort Niobrara, Neb., for duty. S. O. 6, Department of the Platte, January 19, 1885.

## REPORTED MORTALITY FOR THE WEEK ENDING JANUARY 17, 1885.

Deaths reported 2,558; under five years of age, 915; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhoeal diseases) 219, consumption 308, lung diseases 351, diphtheria and croup 151, scarlet fever 63, measles 41, diarrhoeal diseases 44, typhoid fever 38, erysipelas 18, cerebro-spinal meningitis 16, malarial fever 15, whooping-cough 10, puerperal fever 7, small-pox one. From *diarrhoeal diseases*, New York 25, Chicago 6, Boston 4, Brooklyn and District of Columbia three each, Baltimore, Fall River, and New Bedford one each. From *typhoid fever*, Philadelphia 14, Chicago 10, New York, Baltimore, and District of Columbia three each, Boston, Springfield, and Newton one each. From *erysipelas*, New York 8, Philadelphia and Brooklyn three each, Boston two, Baltimore and Nashville one each. From *cerebro-spinal meningitis*, New York 5, Chicago 4, Worcester 3, Philadelphia two, Boston and Nashville one each. From *malarial fever*, New York five, Baltimore four, Brooklyn three, Philadelphia, District of Columbia, and Lowell one each. From *pneumonia*, New York three, Chicago and District of Columbia two each, Brooklyn, Baltimore, and Holyoke one each, from *puerperal fever*, New York and Brooklyn two each,

Chicago, District of Columbia, and Taunton one each. From *small-pox*, Philadelphia one.

In 105 cities and towns of Massachusetts with an estimated population of 1,385,051 (estimated population of the State 1,955,104), the total death-rate for the week was 18.37 against 19.62 and 18.80 for the two preceding weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,762,354, for the week ending January 3d the death-rate was 25.0. Deaths reported 4,195; infants under one year of age 949; acute diseases of the respiratory organs (London) 537, whooping-cough 45, measles 8, scarlet fever 65, diphtheria 36, fever 35, diarrhoea 35, small-pox (London) 33. The death-rates ranged from 20.0 in Plymouth to 34.6 in Cardiff; Birkenhead 26.4; Birmingham 22.8; Blackburn 26.4; Leeds 23.9; Leicester 24.8; Liverpool 28.1; London 24.9; Manchester 26.4; Nottingham 25.2; Sheffield 22.4; Sunderland 22.0. In Edinburgh 18.0; Glasgow 39.1; Dublin 38.5.

The meteorological record for the week ending January 17th in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps:—

Date.	Barometer.	Thermometer.		Relative Humidity.			Direction of Wind.		Velocity of Wind.		State of Weather. <sup>1</sup>			Rainfall.
		Daily Mean.	Daily Maximum.	Daily Minimum.	7.25 A. M.	3.25 P. M.	7.25 A. M.	3.25 P. M.	7.25 A. M.	3.25 P. M.	7.25 A. M.	3.25 P. M.	11.23 P. M.

### TREATMENT OF FRACTURES OF THE FEMUR WITHOUT SPLINTS.<sup>1</sup>

BY D. B. VAN SLYCK, M.D.

FOR more than twenty years I have treated all cases of fracture of the femur coming under my care without splints of any sort, and with results more satisfactory to myself than by the old method with a Liston splint or any of its modifications. Nor have I seen any mode of treatment, with any sort of contrivance or combination of splints, that can at all compare in simplicity, ease of application, efficiency, and uniform good results, with the mode I am about to describe.

As far as I know this originated with, or at least was first given to the profession in print by, Dr. John Swinburn, of Albany, N. Y., who read a paper on the subject before the New York State Medical Society, which published it in its Transactions, I think, but I am not sure. 1861. Dr. Swinburn reported about forty cases treated in this way with remarkable success.

In the same volume, and in connection with Dr. Swinburn's paper, was another by Dr. Thorne, of Troy, N. Y., detailing a number of cases treated in the same way, and also describing a mode of treating fractures of all the long bones on the same principle, giving cases, cuts of apparatus, etc.

I have had no practical experience in treating by this method any fractures but those of the thigh and certain forms of fracture of the leg, and I shall, therefore, confine my remarks to this branch of the subject, though I am decidedly of the opinion that the same principle might be successfully applied to the treatment of other fractures, and my recollection of Dr. Thorne's apparatus and mode of treatment is that they were very ingenious and philosophical, and his cases very successful.

I have never seen a word in print on the subject since 1861, and as I have abundant reason to be satisfied with my own experience in the treatment of fractures of the femur without splints, I concluded to give the result of that experience to the Society, in the belief that it would prove of interest, and in the hope that useful discussion may result.

The mode of treatment in detail, as I employ it, is as follows:—

The bed should be at least two feet longer than the patient. For children, and many people below medium height, any ordinary bed with hair mattress is sufficient. For adults of ordinary stature I have a sort of bunk, or bedstead of plain boards, which a carpenter or, in an emergency, I myself could make in an hour. It should be about eight feet long, and of a width to fit whatever mattress may be most convenient, though the width of a single bed is better. The side pieces may be about a foot wide, and the foot- and head-boards as much wider as desired or your lumber will permit. Thin strips of board in the corners for legs, coming up to the top of the side pieces; cleats on the side pieces to support the cross slats, and all put together with screws or wrought nails, will make a very simple

and easily constructed bedstead, and with a firm, smooth mattress on this you are ready for business.

Now, for an adult, take a strip of adhesive plaster—preferably Martin's—three inches wide and long enough to reach from the knee down the outside of the leg and back on the inside, leaving an ample loop below the foot. On each side of the plaster tear a narrow strip about three-fourths inch wide down to the malleoli. Apply the middle strips on each side of the leg, and the side strips spirally around the leg over them, so that the traction may be distributed as much as possible around the leg, and draw evenly. This is a matter of some importance, as a single strap at the sides is apt to pull off the skin before the treatment is ended. For the perineal band I like a piece of one and one-quarter or one and one-half inch rubber tubing, though the usual band made wide answers well enough. The tubing is easily kept clean, and soft cotton may be kept under it to prevent chafing, and changed when soiled. Tie to each end of about a yard of this tubing strong cords, which are to be passed through a hole in the head-board and tied around a bit of wood. At the bottom of the foot between the strips of plaster place a short piece of lath, or a bit from a cigar-box, of proper length to prevent pressure on the malleoli; tie a strong cord around the middle of the loop of plaster, and pass the two ends through a hole in the foot-board. Now place the patient so that the extension, counter-extension, and shaft of the femur are in line, reduce the fracture, and secure the cord at the foot as you have already done at the head of the bed. A couple of sand-bags on each side will keep the foot in place with the proper eversion of the toes, and two half-hoops from a small butter-tub, wound and fastened in the middle, and placed over the foot, will protect it from the pressure of the bed-clothes. If the sand-bags do not secure sufficient eversion of the toes, a bandage around the foot fastened to one of the hoops will accomplish this purpose. In the first stage of the treatment but little more extension is needed than is necessary to overcome the spasmodic contraction of the muscles. After the process of repair has fairly begun, say after ten or even fifteen days, the provisional callus is still soft and plastic enough to afford ample time to secure the proper length of the limb by gradually increased extension, while, in the meantime, the patient has become accustomed to confinement, and the perineum toughened and prepared for the increased pressure. If necessary to prevent excoriations the foot of the bed may be raised, and a weight and pulley arranged at the foot, and the counter-extension taken off during the daytime. But this should be only a temporary expedient. As a mode of treatment I consider the weight and pulley, or any elastic extension objectionable, for the reason that they do not prevent the spasmodic contraction of the muscles, and it is impossible by this means to graduate the extending and counter-extending force so as to correspond to the actual resistance. In the treatment described you can measure the limb as often as you please, and have only to tighten the foot-cord to keep the injured limb of absolutely the same length as the other, and it is a very easy matter to keep it so.

<sup>1</sup> Read before the Norfolk County Medical Society.

A simple experiment illustrates the principle on which this treatment is based. Take a wooden rod—say a piece of a broomstick, saw it in two anywhere in its length, either transversely or obliquely, surround it with a number of elastic cords fastened at each extremity, so as to allow the middle ends, representing the fracture, to overlap each other. Now make extension and counter-extension, and these ends of necessity fall into opposition and the stick becomes straight. The same experiment may be tried on the cadaver, by dissecting up and separating the muscles of the thigh in their continuity, and breaking the bone, when extension will surely reduce the fracture and all deformity disappear. With the bone surrounded by live muscle in a state of tension, can a better splint be imagined to retain the fragments in position?

If then we have such a splint of nature's provision next the bone where its effectiveness is absolutely perfect, how irrational it is to apply splints and bandages on the outside of the limb with the inevitably evil result of producing, by pressure on the contused and infiltrated tissues, adhesions that prove a serious hindrance to the usefulness of a leg long after the bone itself is substantially sound.

I am aware that the theoretical objection can be raised that some of the muscles—as the adductors—act upon the bone at an angle, and not in the line of the shaft, and that their tendency is to produce lateral deformity. According to my experience the objection does not hold in practice. I think the perineal band has some influence in restraining the lateral traction of these muscles, while the tenseness of the muscles which do directly envelope the bone prevents any displacement. At any rate, I know it as a clinical fact, that when there is no shortening there is no deformity, an argument which will stand against any amount of theory.

Suppose yourself just called to a case of this injury, what do you find? A patient in great suffering, with a crooked shortened thigh, and every fibre of its muscles you can feel under your hand quivering and straining with spasm, as they are gored and irritated by jagged ends of bone at the seat of fracture.

Now let some one grasp the patient under the arms to fix the body, while you seize the ankle of the injured limb, and slowly and firmly draw it down to its normal length, and so fix it till the spasm subsides. What surgeon has not seen in a like case the sudden transition from intense agony to perfect ease and contentment? Still holding the ankle, and maintaining full extension, rotate the leg. Is there any grating of the broken ends of bone together? Not at all, nor does the movement give the sufferer any appreciable pain. The head of the bone rotates in the socket, and the whole limb turns precisely as though no fracture existed, showing that as long as the muscles are held tense, you have a perfectly effective splint immediately around the bone. By reason of this, all through the treatment, the patient, unembarrassed by external splints, enjoys a good degree of comfort and freedom of movement. On one heel and

his elbows, he can raise himself up to use a bedpan, can turn toward the injured side, and assume almost a sitting posture, without pain, displacement of dressings, or injury of any sort to his case. Another important consideration is that the seat of the injury is always open to inspection, a matter of very great consequence in cases of compound fracture. When I have added that in simplicity and ease of execution this treatment surpasses any other, and that I believe it will give far better average results, I may claim to have summed up the case.

My first opportunity to put in practice the method above described was in the United States service, at Fredericksburg, Virginia, in 1863, after the battles of the Wilderness. The mortality after amputations on the field for gun-shot fractures of the thigh was so great that these cases were ordered to be sent to general hospital and primary amputation forbidden. The sufferings of these poor fellows in transportation was so great that, at my request, all such cases in the cavalry hospital were assigned to me, and I made rude bunks, similar to the one I have described, with projecting sides for handles, and of a size to fit an ambulance. After removing all loose pieces, as well as the sharp points of bone in the wound, the men were placed in these bunks, extension applied, and they were carried to their destination in the greatest comfort. Spasmodic action of the muscles was controlled, the sharp ends of bone no longer gored the tender flesh with every jolt of ambulance or car, and, as many a poor fellow expressed it, he felt as though in a new world. After this I managed to improvise some sort of extension and counter-extension for these cases even on the field, with only a stretcher to work with, and was amply repaid for my trouble, by seeing how much more comfortable these cases were.

Since then I have treated in private practice, without splints, twelve cases of fractured femur, two cases of fractured tibia, two cases of fractured tibia and fibula—one of the latter compound.

I had intended to give these cases in detail from my notes, but I should exhaust your patience and will only give results. Of the femur cases, nine were fractures at different points in the shaft of the bone, and in eight the results were perfect, no deformity in any, absolutely no shortening in five, and not more than half an inch in three.

The ninth was an exceedingly unmanageable case—a very nervous and excitable woman, sixty-six years of age—fracture at the upper third. She could not bear a perineal band at all, and I depended on the weight and pulley, and elevating the foot of the bed, and I found out afterward that whenever she thought the extension uncomfortable, she made her daughter put a cricket under the weight. There was two and a half inches shortening, and considerable deformity.

In the other three cases the fracture was intra-capsular, and they were treated with weight and pulley extension, without perineal band. All were women. In the first, aged sixty-five, there was good union, and a useful limb, with one and a half inches shortening; walked without crutches in thirteen weeks.

The other two cases, aged respectively sixty-eight

and seventy-four, recovered with as good results as could have been expected. At the end of eight weeks, when extension was discontinued, the limbs were of equal length, but shortening began at once, and at the end of a month amounted to three inches. Both wore crutches the rest of their lives, being cases of non-bony union.

In the eight typical cases, extension was discontinued in from four to seven weeks; they were on crutches in from five to eight weeks, and cured in from six to eleven weeks.

The last case, treated in October, 1883, illustrates the special advantage of this treatment in a marked manner. B. W., a boy of nine, suffered an oblique fracture of the femur at the lower third, by being run over and kicked while witnessing a football fight. He was sufficiently quiet by day, but perfectly unmanageable at night. He would toss about in his sleep, have night terrors, scream, and kick with his well leg and try to do so with his broken one, and would often be found with his head and part of his body hanging over the side of the bed. This was almost a nightly experience with his parents for three weeks, yet extension was discontinued in four weeks. He was on crutches at five, and walked without in seven. To-day it would be impossible to tell which thigh was broken.

The fractures of the leg were all above the middle, and were treated previously as the thigh case, and with perfectly satisfactory results.

I apply in all cases a silicate of potash bandage before letting a patient out of bed.

#### CASE OF CHRONIC DIFFUSE NEPHRITIS AND AMYLOID DEGENERATION OF THE KIDNEYS, COMPLICATED TOWARD THE CLOSE OF LIFE, WITH GLYCOSURIA AND IXOSTURIA.<sup>1</sup>

BY EDWARD S. WOOD, M.D.

J. McC., thirty years of age, single, born in Glasgow, Scotland, and a stonemason by occupation, was admitted to the nervous and renal service of the Boston City Hospital October 22, 1881, when the following history was obtained, which I have copied substantially from the Hospital Records:—

Family history good; not addicted to drink; has never had venereal disease; when quite young, and at various times since, has had abscesses in the neighborhood of the right hip; has also had necrosis of the tibia, according to his own statement. Four weeks ago the patient was admitted on the surgical side with a hard mass below Poupert's ligament on the right side, which finally broke, and a large amount of pus was discharged. There is now (October 22d) slight oedema of the legs and feet, and some ascites, which were noticed four weeks ago; the patient said he had had the same trouble six years ago in London. There is also slight swelling of the scrotum, considerable headache, no cough, some pain in the chest, palpitation upon exertion, poor appetite, bowels constipated, great thirst, and frequent micturition day and night.

<sup>1</sup> Read before the Boston Society for Medical Observation, January 5, 1885.

October 23d. Was given tinct. digitalis.

October 24th. Analysis of urine: Amount of urine, 1,420 cub. cent. Color, pale. Specific gravity, 1,014. Reaction, acid. Amount of sediment, much. Urophæcin, diminished. Indican, much increased. Chlorides, slightly diminished. Sulphates, normal. Urea, diminished. E. phosphates, slightly diminished. Uric acid, normal. Alk. phosphates, diminished. Albumen, about one-half per cent. Sugar, not tested for. Bile pigments, absent. Sediment, numerous hyaline and granular casts, some of which have fatty renal epithelial cells adherent. An occasional waxy cast. Free fatty renal epithelial cells.

November 2d. Cardiac sounds very faint. No murmur. Liver dulness diminished. Obscure fluctuation of abdomen.

November 5th. Analysis of urine: Amount of urine, 1,450 cub. cent. Color, pale. Specific gravity, 1,012. Reaction, acid. Amount of sediment, much. Urophæcin, diminished. Indican, much increased. Chlorides, slightly diminished. Sulphates, normal. Urea, diminished. E. phosphates, slightly diminished. Uric acid, normal. Alk. phosphates, diminished. Albumen, between one-fourth and one-half per cent. Sugar, not tested for. Bile pigments, absent. Sediment, hyaline, granular, and fatty casts. Fatty renal epithelial cells. No waxy casts detected at this examination.

November 7th. Oedema diminished.

November 18th. Analysis of urine: Amount of urine, 2,395 cub. cent. Color, pale. Specific gravity, 1,012. Reaction, acid. Amount of sediment, slight. Urophæcin, diminished. Indican, much increased. Chlorides, diminished. Urea, diminished. E. phosphates, diminished. Alk. phosphates, diminished. Albumen, about one-half per cent. Sugar, not tested for. Bile pigments, absent. Sediment, hyaline and granular casts. Few fatty and waxy casts. Fatty renal epithelial cells. Total amount of urea, 21.50 gram. Total amount of chlorine, 6.46.

November 19th. Analysis of urine: Amount of urine, 2,118 cub. cent. Color, pale. Specific gravity, 1,012. Reaction, acid. Amount of sediment, considerable. Urophæcin, diminished. Indican, increased. Chlorides, diminished. Urea, diminished. E. phosphates, diminished. Alk. phosphates, diminished. Albumen, between one-fourth and one-half per cent. Sugar, present, 0.3 per cent. Bile pigments, absent. Sediment, hyaline and granular casts. An occasional fatty and waxy cast. Numerous fatty renal epithelial cells.

The peculiar behavior of this specimen of urine with Fehling's copper solution, when testing for sugar, led me to suspect the presence of inosite, or muscle-sugar, also. Therefore, the total amount of urine received the next day was analyzed for that substance. The urine was first freed from albumen by heating upon a water-bath until the albumen had coagulated, and filtering. The filtrate was then precipitated completely with a sugar-of-lead solution, filtered, and the warm filtrate treated with a solution of basic acetate of lead so long as any precipitate occurred. This precipitate, which contained any inosite which was present in the urine, was washed, suspended in water, and decomposed by a current

of sulphuretted hydrogen. The sulphide of lead formed was separated by filtration from the fluid, which was concentrated by evaporation, and, while hot, was treated with four or five times its volume of alcohol. From this mixture the inosite gradually separated in the form of crystals.

These crystals responded to both the Scherer and the Gallois tests for inosite.

Unfortunately, this analysis was not completed until it was too late to obtain more urine for further investigation.

December 1st. Has had headache for a number of days. Given a hot-air bath. December 3d. Some nausea and vomiting. December 4th. Omit medicine. December 9th and 10th. Pilocarpine given. December 11th. Nothing has been successful in making patient sweat. Has had hicough, which was controlled by atropine. Given solution of pilocarpine. Has passed no urine for twenty-four hours; catheterized, but none obtained. Died at 11.35.

*Autopsy*, by Dr. W. W. Gannett, twenty-three hours after death.

Body small, much emaciated, poorly developed. Slight lividity. Rigor mortis present.

Right thigh flexed on the pelvis, and moves only with the pelvis.

Neither the pericardium nor the heart showed any appearances worthy of note. The pleural surface on the left side adherent over the apex; on the right side adherent over the whole lung by old firm adhesions. Left lung contracted and dark. On section of the lung the surface is dark red, at the apex a dried-apple appearance; the vessels contain considerable dark fluid blood. The right lung only partially retracted, much denser than the left, only slightly crepitant, and pitting on pressure. On section the surface is moist, yielding considerable aerated fluid on pressure.

The spleen is about one half as large again as normal, of usual color; density considerably increased. On section trabeculae rather indistinct; follicles not to be seen at all, and the whole surface presenting a uniform, homogenous, pale-red, translucent appearance.

The kidneys about one third larger than usual, pale in color, density considerably increased; capsule detached with some difficulty, removing with it, here and there, small particles of kidney substance. The external surface presents a mottled red and gray appearance, the gray portion being translucent. On section the cortex is diminished about one third in thickness. The tubular regions are indistinct, the cut surface showing a mottled appearance like that already described on the external surface, with the addition of here and there yellow opaque areas.

The bladder not remarkable.

The oesophagus and stomach not remarkable.

The mucous membrane of the small intestines is deeply injected, thickened, and velvety. The contents are thin, grayish, and very foul-smelling fluid. The large intestines presented similar appearances, though less in degree. The liver was of the usual size, color, and density, showing on section nothing worthy of special note.

Aorta not remarkable.

Examination of calvaria and dura not remarkable. Pia and brain itself remarkably pale, the vessels containing but little blood. Beyond this nothing remarkable.

The diagnosis made from the autopsy by Dr. Gannett was: Anæmia of the brain; chronic adhesive pleurisy; atœmia of the right lung; diffuse amyloid degeneration of the spleen; chronic diffuse nephritis, with amyloid degeneration of the kidneys, and acute diffuse catarrhal enteritis. There was also complete ankylosis of the hip-joint, of which the record was not completed at the time of copying.

The following record of the amount of urine passed daily while the patient was in the hospital presents some points of interest:—

	Cub. Cent.		Cub. Cent.
October 24th . . .	1,420	November 15th . . .	2,425
October 25th . . .	1,272	November 16th . . .	2,365
October 26th . . .	1,508	November 17th . . .	2,425
October 27th . . .	1,242	November 18th . . .	2,395
October 28th . . .	1,360	November 19th . . .	2,118
October 29th . . .	1,745	November 20th . . .	2,247
October 30th . . .	1,804	November 21st . . .	2,305
November 3d . . .	1,508	November 22d . . .	2,425
November 4th . . .	1,420	November 23d . . .	2,395
November 5th . . .	1,450	November 24th . . .	2,307
November 6th . . .	1,360	November 25th . . .	2,395
November 7th . . .	2,100	November 26th . . .	2,365
November 8th . . .	2,070	November 27th . . .	2,336
November 9th . . .	2,365	November 28th . . .	2,395
November 10th . . .	2,129	November 29th . . .	2,247
November 12th . . .	2,484	December 7th . . .	838
November 13th . . .	2,395	December 10th . . .	680
November 14th . . .	2,573		

The interesting features in regard to the quantity of urine passed are: the sudden increase to 2,100 cub. cent. on November 7th, while, previous to that date, it had averaged considerably less than this (1,462 cub. cent.). After this, until within less than two weeks before death, the amount did not fall below 2,000 cub. cent., whereas usually in either chronic interstitial nephritis or amyloid degeneration the amount of urine falls to or below the normal for a considerably longer period before death. Unfortunately, no test was made for sugar or inosite previous to November 7th, so that it is impossible to say whether glycosuria first appeared at that time, and was the cause of the sudden increase in the amount of urine, or not.

Inosite has been found several times associated with grape sugar in diabetes mellitus and in chronic Bright's disease. In the celebrated case of Vohl (*Journ. de Physiol.*, vi. 314) the proportion of grape sugar gradually diminished, while that of inosite increased, until the amount reached eighteen to twenty grammes in twenty-four hours. By puncturing the floor of the fourth ventricle in rabbits Gallois sometimes found inosituria to be produced, and sometimes glycosuria. It has been found in the urine of diabetes insipidus in two cases by Schultzen, in two cases by Strauss, in one case by Gscheidlen, and in two cases by Külz. Strauss has also found it in the urine of healthy men after drinking excessive amounts of water, as ten liters in twelve or twenty-four hours, and he concludes that the large amount of water flowing through the body removes the inosite from the tissues (muscles, kidneys, liver, and lungs) before it has time to become changed into carbonic acid and water.

## REPORT ON PROGRESS IN GYNECOLOGY.

BY F. H. DAVENPORT, M.D.

## GONORRHEA OF THE FEMALE GENITAL ORGANS.

Dr. BUMM<sup>1</sup> refers to the discovery of the Gonococcus, the germ peculiar to gonorrhoea, as of the greatest importance, but regrets that its value has not been more appreciated in cases of this disease occurring in women. With the exception of this we have no sure means of diagnosis. Venereal warts so called, "condylomata acuminata," undoubtedly occur without any gonorrhoeal infection, and inflammation of the vulvo-vaginal glands, though usually of gonorrhoeal origin, yet occurs too seldom to be of much diagnostic value. The urethritis, when not caused by tumors or violence, is always a result of infection, and were it not for its rapid course and tendency to heal, would be useful in a majority of cases.

Then follows a description of the "gonococcus," its distinguishing marks from other microbes, and the various methods of cultivating and staining it. There appear to be two other forms of micro-organisms which occur in the vaginal secretions so similar to the gonococcus that it is with difficulty they are distinguished, even by the practised observer.

The generally accepted opinion is that vaginal gonorrhoea is the most frequent form. The author takes exception to this view, however, claiming that the vaginal mucous membrane anatomically resembles the epidermis, and hence is not so likely to be infected by the morbid material; and that in those cases where we find redness, swelling, and increased secretion, these conditions are generally due to the irritating character of the pus which comes from the infected cervix or urethra. The rapid yielding of the symptoms to the simplest remedies also speaks for this view, as well as the fact that numerous cases of gonorrhoea of the cervix without the vagina being implicated have been observed.

The most frequent seat of the gonorrhoeal infection is, therefore, the cervix uteri, a location especially favorable on account of its anatomical peculiarities. The rôle the vagina plays is that of receptacle and sometimes breeding-place of the contagium.

The gonorrhoea of the uterus and its adnexa is the most stubborn to yield to treatment, and its results in endometritis, salpingitis, oöphoritis, and peritonitis the most serious.

## GONORRHEAL AFFECTIONS OF THE APPENDAGES OF THE UTERUS, AND THEIR TREATMENT.

Sanger, of Leipzig, in a paper read before the gynecological section of the fifty-seventh meeting of the German Naturalists and Physicians at Magdeburg,<sup>2</sup> expresses the opinion that these troubles have not received the attention they should. Gonorrhoea is the cause of a greater number of severe chronic affections of the pelvic organs than puerperal fever or syphilis, and of all gynecological cases about one ninth originate in this way.

The severity depends upon whether the tubes, ovaries, and pelvic peritoneum are affected or not, and of all forms of disease of these organs the gonorrhoeal are the most frequent and the most serious.

Noeggerath's division of these affections into three forms of perimetritis, an acute, a relapsing, and a chronic, and ovaritis, the author would reject for one based on the seat of the trouble. He makes four divisions: (1) of the urethra; (2) of the vulva and its glands; (3) of the vagina and uterus; (4) of the uterine appendages and the neighboring peritoneum. The author places less reliance on the presence of the gonococcus as a means of diagnosis, since the researches of Bumm have shown the difficulty of distinguishing these from other similar germs, and considers that in the majority of cases the history and examination are sufficient to establish the gonorrhoeal origin.

In the way of prophylactic treatment the author would particularly urge advising against marriage until every trace of gonorrhoea had disappeared. The treatment of acquired gonorrhoea in the woman should not be considered so hopeless as many authors, especially Noeggerath and Fritsch, have thought. For the affection of the urethra, vagina, and uterus, corrosive sublimate injections are most effectual. For the later stages applications of solutions of nitrate of silver, iodine, or dilute nitric acid may be tried.

When the uterine appendages are diseased their removal is recommended as holding out a definite prospect of cure. The writer finally gives the account of four cases operated on by him. One was completely successful. In the other three some cellulitis followed, which, however, in two cases promptly disappeared.

## MURIATE OF COCAINE IN GYNECOLOGY.

Dr. Polk<sup>3</sup> reports two cases where this drug was used to produce local anesthesia for the operation of trachelorrhaphy. In the first case, after thoroughly washing the cervix and its neighborhood, a four per cent. solution of the drug was painted on with a camel's-hair brush, and repeated twice at intervals of two or three minutes. Within three minutes of the last application the operation was begun. It lasted forty minutes, and the only complaint the patient made was of a feeling of soreness the last ten minutes. The second case was a more nervous, sensitive woman, and the anesthesia lasted only twenty minutes. A fourth application was then made directly to the cut surface, and the operation completed without further pain. Dr. Polk was of the opinion that the drug not only blunted sensibility but retarded the appearance of blood upon the cut surface.

In an article on "The anæsthetic use of the hydrochlorate of cocaine upon parts of the body other than the eye," Dr. H. A. Kelly<sup>4</sup> gives the notes of two cases. The first was one of bilateral laceration of the cervix, where after sensitiveness had been tested by the tenaculum, and found to be marked, a pledget of cotton saturated with an eight per cent. solution of muriate of cocaine was laid upon the parts. In seven minutes sensation was abolished, and the operation was begun. It lasted two hours, during which time the patient made no complaints, and only winced when the sutures were introduced. The second case was one of excessive sensitiveness of the uterus, where the passage of a sound was ex-

<sup>1</sup> Archiv für Gyn., Band 23, Heft III.<sup>2</sup> Centralblatt für Gynäkologie, No. 41, 1884.<sup>3</sup> Medical Record, November 1, 1881.<sup>4</sup> Medical News, December 27, 1881.

ceedingly painful, and always followed by a night of suffering. A pledget of cotton wet with a four per cent. solution of the drug was introduced into the canal. An Ellinger's dilator was then passed without pain, though the dilatation itself was painful. She had none of the usual after pain.

#### SO-CALLED OBSTRUCTIVE DYSMENORRHEA.

Dr. Burton<sup>5</sup> refers to the difference of opinion which exists among leading gynecologists as to the existence of a form of dysmenorrhœa due to obstruction from closure of the uterine canal; some holding that a spasmodic closure of the internal os in some cases, or a flexion by which the calibre of the canal is lessened in others, is a cause of dysmenorrhœa; while other good observers claim that no amount of flexion can so affect the size of the canal as to cause obstruction. With the view of throwing some light upon this vexed question, the author examined six women who suffered from paroxysmal pains during menstruation, when such pain was at its height. He found that so far from there being spasm or constriction at the external or internal os, there was actual dilatation, and the canal was really more patent from one end to the other, than at any other period of the month. In cases of limp antelexion he found that the menstrual congestion had so affected the uterine structures that the canal was almost straight.

The writer considers the pain to be due to pressure on the nerves from congestion.

#### RAPID DILATATION OF THE UTERINE CANAL.

Dr. Goodell<sup>6</sup> in this paper gives his experience with other methods of dilatation, and describes his present practice. He formerly enlarged or straightened the uterine canal either by tents or by Sims's operation, until the occurrence of two deaths, one from septicaemia following Sims's operation, and one from peritonitis after the dilatation with tents and curetting, induced him to try rapid dilatation. Since then he has had no such mishaps. He recommends two Ellinger's dilators of different sizes, the smaller one to pilot the way for the larger, which is a powerful instrument, and opens to an outside width of an inch and a half.

Dr. G. employs rapid dilatation in cases of dysmenorrhœa or sterility from flexion, or from stenosis, and uses the larger instrument under complete anesthesia. For slight dilatations in office practice the more delicate instrument is strong enough, and an anesthetic is not needed.

After complete dilatation the canal rarely returns to its previously angular or contracted condition; in a few cases, however, the operation has to be repeated. This method is also useful to open the canal to facilitate the use of the curette, or to make applications to the uterine mucous membrane, and especially in order to explore the womb with the finger.

Dr. G. thinks he has performed this operation under ether over three hundred times, and gives statistics of one hundred and sixty-eight cases. Of sixty-two unmarried from whom data could be obtained, thirty-three were cured, seventeen more or less improved, and seven not improved. Five of these seven had their ovaries removed subsequently,

and in all they were so altered by disease as to make the dysmenorrhœa otherwise incurable. Fifty-three of the married were heard from. Of these thirty-nine were cured, ten improved, and four unimproved. A very fair proportion of those who were in a condition to conceive, became pregnant afterward.

#### STATISTICS OF UTERINE CANCER AND ITS OPERATIVE TREATMENT.

Dr. Hofmeier<sup>7</sup> in this paper adds a good deal of valuable information on this subject from the records of the Berlin Gynecological Polyclinic, and from Schroeder's private practice of the last seven and three-quarters years.

Of 16,800 gynecological patients of the Polyclinic, 3.6 per cent. had cancer of the womb; of 9,400 private patients, 2.18 per cent., making of 26,200 patients altogether 3.1 per cent., or 812. (The statistics for fibroids were 1.9 per cent. of the clinical, and 5.7 per cent. of the private, patients.)

Of the 812 women who had cancer of the uterus there were only 39 who had never had children. 76 had had more than 10, and the average was five. (On the contrary, of the patients with fibroids who numbered 822 in 21,000, 32 per cent. had never had children.)

As regards the seat of the affection, in 236 it was confined to the vaginal cervix; in 181 it had affected the whole cervix; there were 28 of the body, and in 367 its point of origin could not be determined.

The average age of patients with carcinoma of the vaginal cervix was 42, only one being over 60. The average number of births was six, there being only seven nulliparae and 33 uniparae among the 236. The average age of those with cancer of the whole cervix was 17, 20 patients being over 60. The average number of births was 6.5, and of the 181 there were four nulliparae and 23 uniparae. Of patients with cancer of the body the average age was 54.5, with six of the 28 over 60 years of age; 21 per cent. were nulliparae, while only 2.5 per cent. of those where the cervix was primarily affected had never borne children.

Of the 812 cases, 160 were operated upon with a hope of radical cure. There were 105 vaginal amputations, 31 total extirpations by the vagina, eight by Freund's method, and 13 laparotomies with supra-vaginal amputation. Of these thirty-one died within the first few days, principally from hemorrhage and septic processes. There had been an interval of two years since 92 had been operated upon, of which number 77 were still alive. Of these 28 were well, 33 showed return of the disease, and with regard to 16 the condition was not known.

Of the 28 who were still healthy two years after the operation, 20 were amputations of the cervix, three vaginal total extirpations, four supra-vaginal amputations by means of laparotomy, and one Freund's operation.

These are results which compare favorably with those of the extirpation of malignant growths in other parts of the body, and are calculated to silence the objections of those who question the value of radical operations for cancer of the uterus.

<sup>6</sup> N. Y. Med. Journal, October 25, 1884.

<sup>7</sup> Zeitsch. für Geburtshilfe und Gynäkologie, Band, X.

The article contains besides interesting operative details, and there are added a number of drawings of extirpated uteri and uterine segments.

#### THE CURETTE: ITS PLACE AND ITS POWER IN UTERINE THERAPEUTICS.

Dr. Geo. T. Harrison<sup>8</sup> in this paper seeks to define the value of this instrument. He refers first to the various opinions which have been expressed about it by writers, from the warm praise of it by Sims and Martin, to the sweeping condemnation by Emmet and others. He then describes the modifications which the instrument has undergone from its introduction by Récamier in 1846 to the present time.

The use of the curette he would consider indicated in the following morbid states of the uterine mucous membrane: (1) in sarcomata and carcinomata of the inner surface of the body of the uterus, in cases where more radical measures cannot be employed, though the result is of course only palliative; (2) in cases of retention of the products of conception. This applies particularly to the early months when the cervix is apt to be too unyielding to admit the finger; (3) in the various forms of endometritis characterized by menorrhagia and metrorrhagia. In some of these cases the sharp curette is needed in order to remove the deeper layers of the diseased mucous membrane; (4) in small benign neoplasms such as mucous and fibrinous polypi, and adenoid growths; (5) to a limited extent in the secondary endometritis of acrolar hyperplasia, and the endometritis complicating myoma; (6) for diagnostic purposes.

The author concludes with a description of the methods of operating, and cautions to be observed in the after treatment.

### Therapeutic Memoranda.

#### MONSEL'S IRON IN DIARRHOEA.

BY EDWARD T. WILLIAMS, M.D.

I HAVE been urged by one or two friends to communicate to the JOURNAL something I said before the Norfolk District Medical Society, at a recent meeting, on the use of the powdered sub-sulphate of iron in diarrhoea.

Ever since I began practice in 1868 I have been looking for a really satisfactory astringent in chronic catarrh of the bowels. There is, as every one knows, a class of cases where the ordinary vegetable astringents fail to act, or at least act too feebly to do real good. The intestinal lining is in an ulcerous, or quasi-ulcerous, condition, and requires the potent action of a mineral astringent to treat it, as in cases of external ulcer. The acetate of lead is one of the best remedies in these cases, but cannot be safely given for any great length of time. Oxide of zinc in pill form is safe and efficient, but with children, who must take it in powder, often vomits and gripes. Sulphate of copper and nitrate of silver are still harsher, and for children quite out of the question. Subnitrate of bismuth is worse.

I began trying, in 1876, at the Seashore Home,

iron alum (the official sulphate of iron and ammonia). I found it better than anything I had previously tried and have used it freely ever since. It is not quite so well borne by the stomach as lead and bismuth, but far better than zinc or copper. The dose for a child is from one to three grains; for adults, from three to ten. At the Seashore Home we make up powders containing one grain of the salt to a twelfth of a grain of opium, giving one or more for a dose according to the age of the child. For adults the pill form is of course preferable. I have had the best results from its use.

Last summer I began using Monsel's salt in its place both in public and private practice. This I did from my experience of its great efficiency as a styptic, and a presumption that it might do equally well in diarrhoea, and have found it even better than iron alum. I have tried it only in the dry form, manufactured by Squibb under the name of Pulvis Ferri Subsulphatis. In this State it is not official, though it is precisely the same as the official liquid Ferri-Subsulphatis evaporated to dryness. It may be given in the same doses and in the same way as iron alum.

As I know nothing in print on this subject, you will perhaps excuse this note. It may be welcome to such of your readers as are interested in the homely subject of therapeutics.

#### COCAINE IN URETHROTOMY.

OPERATION BY DR. G. M. GARLAND.

REPORTED BY W. J. GLEESON,

House Physician, Carney Hospital.

PATIENT, aged fifty-eight, contracted gonorrhoea twelve years ago which resulted in gleet, the latter persisting ever since.

During last three or four years he has had scalding, increasing difficulty in micturition and some urethral hæmorrhage, though the latter had been very slight and not at all constant.

On examination, No. 12 French acorn bougie passed with difficulty through the anterior portion of the penile urethra, and on withdrawal was followed by a little blood. Seven distinct hitches of the instrument within three inches of the meatus could be readily counted.

At 9.56 a.m. forty minims of a four per cent. solution of chloride of cocaine were injected into the urethra and retained four minutes by pinching the meatus. At 10.07, the operation by the Otis method was begun and lasted twenty minutes.

The patient lay perfectly quiet and only winced once or twice during the repeated cuttings. He expressed himself as delighted with the effect of cocaine. After the division of the strictures up to 33 French, a No. 28 steel sound was passed into the bladder, the patient declaring that he scarcely felt it at all. Seven hours later he passed his water, and remarked that the pain attending this act was greater than that of the operation itself.

As showing the previous irritability of the urethra, I may say that the single introduction of a sound by Dr. Garland at his first examination of the case caused far greater immediate and subsequent suffering than did the operation itself.

## Reports of Societies.

### BOSTON SOCIETY FOR MEDICAL OBSERVATION.

JANUARY 5, 1885. DR. R. H. BLOOD reported a case of puerperal convulsions coming on some hours after delivery, in which pilocarpine and bleeding were resorted to.

DR. J. STEEDMAN spoke of the advantages of ether in such cases.

DR. W. L. RICHARDSON said that post-partum convulsions were rarer and more severe than other forms. He spoke of a case which came to the hospital ten days ago, at nine in the morning; she was delivered of a healthy child one hour later; everything passed off well, but her face was somewhat swollen and she complained of slight headache. When her urine was drawn it became nearly solid with albumen on heating. The attendant was cautioned to look out for convulsions, and acetate of potash was ordered. In about two hours she had a convulsion, followed by two more. One sixth of a grain of pilocarpine was given and repeated once, causing only a slight amount of perspiration. Extra bedclothes were given, and a piece of small stovepipe, with an elbow, was arranged so that one end led under the bedclothes and the other was placed over a lighted kerosene lamp standing on the floor, thus giving a temperature of about 120° in the bed. A profuse perspiration soon followed, and there were no more convulsions. Five days later patient was doing well. He usually placed main reliance on pilocarpine in such cases; does not think bleeding is often indicated. In cases of ante-partum convulsions he had seen, several times, a more profuse hemorrhage than usual at time of delivery. In regard to ether he always had an attendant at the bedside until the urine has started, with instructions to etherize when any sign of convulsion appeared; and has even kept a patient under its influence for thirty-six hours. He advised giving ether at once to control the convulsion, then pilocarpine, and then bromide of potash, with chloral, to prevent a return. In reply to a question he stated that he used morphia for some five years in such cases, but now has given it up. He thinks the kidneys act less readily when morphia has been given than when the other treatment has been followed.

DR. WOOD spoke of a decomposition which takes place when chloral is given with syrup, alcohol, or bromide of potash, in which the chloral is decomposed and a chloral alcoholate formed which rises to the surface, and unless the bottle is shaken before measuring out the dose we may get a much harsher and more dangerous effect than was intended.

DR. DAVENPORT called attention to the fact that very little pure bromide of potash was to be had; that it always contained carbonates which decomposed the chloral. If the chloral is given in aqueous solution, with the addition of a small amount of chloroform, it keeps better and does not decompose.

DR. E. S. WOOD reported a

CASE OF CHRONIC DIFFUSE NEPHRITIS AND AMYLOID DEGENERATION OF THE KIDNEYS, COMPLICATED TOWARD THE CLOSE OF LIFE WITH GLYCOSURIA AND ISOSTERIA.<sup>1</sup>

DR. GANNETT said that he had made an examination of a case that afternoon, in which the kidneys exactly resembled those in Dr. Wood's case; there was an ankylosis between the head of the femur and the acetabulum, and there had been considerable absorption of bone, and about the femur a considerable infiltration of gelatinous material; no examination for sugar had been made in the urine of this case.

DR. F. H. HOOVER remarked concerning a case of acute otitis media with naso-pharyngeal catarrh, in which cocaine had been used with marked success: "The value of cocaine is now so firmly established that I dare say one is hardly justified in taking up the time of the Society by saying much about it. But I have recently used it with so much success in an important case, to which I was called by Dr. Kyle, of South Boston, that I would like to say a word concerning it. The case is of interest from more than one point of view, and illustrates very vividly the effect of cocaine, as it afforded relief in this instance which could not have been obtained so rapidly by any other means. Without entering into a detailed history of the case, it will be sufficient to state that I found the young patient suffering intense pain from an acute inflammation of the middle ear, which was accompanied by a copious serous discharge. This condition in the ear was consequent upon, and complicated by, a severe eustachian inflammation of the nose, pharynx, and larynx. There was some cough. Respiration through the nose was impossible. In addition, therefore, to the pain, we have all the discomforts of mouth-breathing. The patient was in bed, with her head banded up, and a hot-water bottle by the side of the ear, weak and pale on account of the pain, which was aggravated each time she moved her jaw or attempted to clear the nose. Clearly the first thing to be done was to relieve the pain and free the obstructed nostrils. It was doubly important in this case to have unimpeded nasal respiration; for, if we accept with Tillaux, Woakes, and others that the physiological opening of the Eustachian tube is the external nasal meatus, we may say that we had here a closure of the tube throughout its entire length. To treat, therefore, rationally the ear disease, as well as to remove the distress that breathing only through the mouth implies, free nasal respiration was imperative. This was speedily accomplished by a few drops of a four per cent. solution of cocaine applied in the following manner: The ear was carefully wiped out with absorbent cotton. There was a small perforation in the posterior inferior segment of the membrana tympani. A few minims of the solution, very warm, were dropped into the auditory meatus, which was followed almost instantly by complete cessation of the pain. The interior of the nasal cavities was then thoroughly 'cocainized' by means of the cotton-tipped probe. Immediately the swollen and congested tissues collapsed, an effect we can now always count upon with absolute certainty. It may

<sup>1</sup>See pages 123, 124.

truly be said that in less than one minute the entire character of this patient had changed. The pain, which extended over quite an area around the ear and down the neck, had vanished, and free respiration was going on through the natural channels, which were but a moment before occluded. The result, in fact, to use the sufferer's own words, was 'simply magical.' The treatment in addition to the cocaine, I need scarcely state, was on general principles."

DR. HOOVER stated that after the application of cocaine the patient was given chloral. The next day the nose had become again occluded, but yielded readily to cocaine. The effect lasts from one to three hours, but after a second application the nose often remains open.

DR. LANGMAID spoke of trying the drug with similar effect.

DR. FITZ referred to some cases where the actual cautery had been used in the nasal passages without any pain, the parts having been first treated with cocaine.

## THE NEW YORK COUNTY MEDICAL ASSOCIATION. ANNUAL MEETING JANUARY 19, 1885.

### ELECTION OF OFFICERS.

THE annual election of officers was the first business in order, and resulted as follows:—

President, Dr. Charles A. Leah. Vice-President, Dr. Edward G. Janeway. Recording Secretary, Dr. P. Brynberg Porter. Corresponding and Statistical Secretary, Dr. C. S. Bull. Treasurer, Dr. Whitman V. White. Member of the Executive Committee, Dr. Wm. T. White.

### DISTRICT ASSOCIATIONS.

The Treasurer's report having been read and other executive business transacted, Dr. J. W. S. GOULEY presented the following resolutions, which were adopted:—

*Resolved*, That the President of the New York County Medical Association appoint a committee of three—with power to increase its number—to take into consideration the propriety and expediency of organizing district associations, in New York City, as branches of this Association.

*Resolved*, That, in case that this committee should decide to report in favor of such district associations, they be authorized to prepare a plan of organization to be presented to this Association for action at as early a date as practicable.

The chair appointed Drs. Gouley and A. Flint, Jr., on this committee, with power to select a third member.

On motion of Dr. A. FLINT, JR., the Secretary was requested to complete the collection of papers and discussions of the Association which had been published in the medical journals during the past year, and to preserve copies of all such printed records in the future.

### THE RETIRING PRESIDENT.

DR. DETMOLD then made some appropriate remarks on vacating the chair, in which he spoke of

the remarkable success which the Association had achieved during the first year of its existence. This success, he said, would serve to mark in all time to come one of the most brilliant events in the medical history of this country; and in his own professional career, which had now lasted for over half a century, there was nothing upon which he looked with so much pride as the fact that he had been selected to be the first President of the New York County Medical Association. He then thanked the members for their unvarying courtesy and indulgence toward himself, as well as their hearty co-operation, and bespoke the same for his successor; after which he spoke of the great scientific value of the papers which had been read before the Association, and of papers read and the discussions which they had elicited, and requested a full attendance at all the meetings of the Association for the encouragement of those who were to read papers in the future. He then introduced the President-elect, Dr. Charles A. Leah, who delivered a short

### INAUGURAL ADDRESS,

in which he made a number of suggestions for increasing the efficiency of the Association. The clinical advantages now offered in New York were so great that he thought much benefit could be derived from the narration of cases of special interest, and he encouraged each member of the Society to contribute something of this kind to the proceedings, however insignificant it might be. He believed that the suggestions made in the resolutions of Dr. Gouley, if properly carried out, would be of the greatest benefit to the Association, and he also expressed the hope that the transactions would be embodied in permanent form.

On motion of Dr. AUSTIN FLINT, SR., the thanks of the Association, with its best wishes for his continued health and happiness, were unanimously tendered to the retiring President, Dr. Detmold.

## CLINICAL SOCIETY OF THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL.

### SOME EXPERIMENTS AND OBSERVATIONS IN REFERENCE TO THE DIAGNOSTIC SIGNIFICANCE OF EPITHELIAL CELLS WHEN FOUND IN THE URINE.

By William Henry Porter, M.D., associate professor of Clinical Medicine and Pathology in the New York Post-Graduate Medical School and Hospital, etc.

It is well known that there is great variety in the form of the epithelial elements that are found in the urine, some of which are derived from the urinary tract, others from the generative organs, while a less number may come from the air-passages, mouth, or skin. But of all these the variety known as flat or pavement cells, the tailed cells, and the small angular, commonly called "renal" cells, have given rise to the most discussion.

Naturally, epithelial cells from the urinary tract are found most frequently in the bladder whether of the female or male. On the other hand the

urine of the female almost invariably contains a peculiar sort of large and angular cell that has been regarded as distinctively diagnostic of the sex. But it is well to state here that all varieties, sizes, and forms of epithelial cells may come from the bladder, the ciliated form excepted.

The structure of the bladder distinctly explains this, because it is divisible into three separate layers. The innermost or deepest is composed of several strata of small cells, varying in size and shape, but usually cuboidal or rounded in outline. When these cells are desquamated rapidly they increase in size and have a more globular form, especially in catarrhal conditions, or when the membrane is inflamed.

The intermediate plane is made up of a single, or in part double, layer of pyriform cells. Their tail-like prolongations are either single or double, but usually single, and dovetail in between the epithelial cells of the deeper layers.

The third or outer layer is composed of a form of flattened cells called transitional. These cells are composed of large masses of protoplasm which usually appear to have two or more nuclei, but often this phenomenon is an optical illusion, the apparent nuclei being produced by the fossa on their under surface where it rests upon the underlying corpuscles.

In cases of an ordinary catarrhal condition or inflammation, the epithelial membrane may be desquamated in separate layers in its entirety, the three strata adhering together, and appearing together under the microscope.

But a careful examination of the mucous membrane of the renal pelvis, of the ureter, and of the vagina demonstrates that, in all these regions, the membrane is composed of three strata of cells similar to those found in the urine.

Now, though the variety known as vaginal epithelial cells has been said to be the most common in female urine, investigation tends to show that these peculiar cells are quite as likely to come from the bladder, and even from the ureter and pelvis of the kidney.

In this connection there is another quite interesting point of medico-legal interest in connection with these cells, some alleging that they are always absent in the virgin.

My attention was especially called to this subject when making a necropsy upon a female patient aged eighteen, who had died twenty-four hours after a fracture of the skull. When the kidneys were examined they unexpectedly gave every macroscopic evidence of a chronic parenchymatous metamorphosis. The urine was desired for examination to see if it contained evidence of the renal lesion, which it did in every particular. It was also found to contain an abundance of large flat cells identical with commonly called vaginal, and single and bifid cells also were abundant. In this case the urine was not withdrawn through the urethra, but the bladder, which happened to be distended, was opened from the abdominal cavity, and its contents were withdrawn through a clean syringe.

Excluding the vagina and tracing the origin of these flat cells to the bladder, their frequency in the female, and rarity in the male, urine can be explained

as follows: From the loose attachment of the bladder to the movable anterior wall of the vagina there is of necessity greater mobility in the female than in the male.

The frequent motion and tendency to pouching of the trigonum vesicale, and the more frequent over-distention in the female, tend to excite a mild catarrh which damages the epithelial cells, loosens their attachment, and easily explains their frequent and abundant desquamation.

On the other hand, the firm attachments of the male bladder to the surrounding tissues, and its less mobility and distensibility, tend to hold the epithelial cells in their proper relations.

Regarding the dependence upon the tailed cells as a positive diagnostic point in pyelitis, a series of observations were cited showing the impossibility of locating with certainty the source of any given variety of epithelial cells when found in the urine. These experiments were made from subjects in which the membrane was free from any inflammatory process at the time of death. If the membrane were the seat of any inflammatory action, the rapid metamorphosis, subdivision, and desquamation of the cells would tend to make the similarity still greater.

Renal epithelial cells are often described as occurring free in the urine and being recognizable as such, under the microscope, but observations and comparisons show that it is absolutely impossible to diagnose with certainty between renal cells and those of the deeper layer of the mucous membrane of the urinary tract. Either one might be mistaken for the other.

Buccal epithelial cells may occasionally find their way into the urine, as when the receptacle for the urine serves the purpose of a spittoon. They are, however, said to be distinguished from the vaginal cells by a more regular outline and being larger; samples of these cells were prepared for comparison, but in size and shape they presented so many points in common that no marked difference could be drawn. Measurements of these cells gave the same results as in the cells taken from the urinary tract and vagina.

Ciliated epithelial cells are occasionally found in the urine, and may come from the air-passages through the sputa, but they are more likely to come from the uterus or Fallopian tube in the female and the ejaculatory ducts, vesiculae seminales, or vas deferens in the male.

The results obtained by Dr. Creedon and the observations in these two cases add additional proof to the trustworthiness of the statement of Professor Ebslein in Ziemssen's *Cyclopædia of Medicine* (vol. xv, p. 571): "that the occurrence of tailed epithelial cells in purulent urine was the most positive indication that the patient had pyelitis."

The conclusions deduced from this study are: that flat epithelial cells are found in the urine of females more frequently than in males; that they originate both from the vagina and bladder, and probably more frequently from the bladder and urinary tract; that they desquamate more frequently and in larger numbers from the female bladder on account of the loose attachment and greater mobility in the former, and are more frequent after virginity on account of the increased mobility of the genito-urinary tract;

that isolated angular "renal" cells cannot be distinguished from those of the third strata of epithelia at any point of the urinary tract; that no distinctive feature can be ascribed to any cell or set of cells by which their place of origin can be localized.

# PATHOLOGICAL SOCIETY OF PHILADELPHIA.

THURSDAY evening, December 11, 1884. The President, DR. SHAKESPEARE, in the chair.

## THREE CASES OF TUBERCULOSIS.

presented by Dr. Edward T. Bruen.

The following cases I desire to submit to the Society because they have seemed to me valuable as showing grounds for the belief in the non-specific inflammatory character of some tubercular lesions.

CASE I. — Carrie C., aged eighteen years, was admitted to the venereal wards of the Philadelphia Hospital, June, 1884. She was the type of a strong, healthy Irish girl, and until a short time previous to her admission had never been ill in her life. When admitted she was suffering from secondary syphilis and gonorrhoea, the primary syphilitic lesion having occurred three months previous. She was put on the usual specific treatment and seemed to be doing very well until about the twentieth of July, when she began to complain of abdominal pain in the right inguinal region, and a vaginal examination showed a purulent discharge exuding from the mouth of the uterus. Upon dilation of the os with sponge tents an abundant purulent discharge followed, but after transitory improvement an abscess formed in the cellular tissue of the vaginal wall, which finally ruptured, and, after discharging freely, closed. After a period, during which there seemed gradual improvement, she again commenced to complain of abdominal pain and was transferred to the medical ward in October, from which time health progressively declined, great emaciation occurred, and she died November 26th.

*Autopsy.* Thorax — The pleura were normal, presenting neither effusion nor adhesions. Lungs were extensively hepatized and oedematous, presenting marked signs of croupous pneumonia.

Heart — Pericardium was normal. The heart itself showed no valvular lesions. The cardiac tissue, however, was pale and atrophied. There was a large ante-mortem clot both in right and left sides of the heart.

Abdomen — There was no peritoneal effusion. The omentum as well as the whole peritoneal surface was studded with minute nodules of a tuberculous nature. There were adhesions between all the viscera. Catarrhal changes were present throughout the intestines.

Liver — There was extensive peri-hepatitis. The connective tissue was everywhere covered with minute tuberculous nodules. The parenchyma of the liver was granular and rather anæmic, but no tubercles were visible microscopically.

Spleen — This organ was slightly enlarged, but of normal consistence. There was slight perisplenitis, and numerous tuberculous nodes throughout the whole splenic substance. Kidneys were slightly above normal size. Their surface was smooth, but, as well as the parenchyma, presented

whitish-yellow spots, alternating with congested points. There were also lesions indicating parenchymatous nephritis.

Pelvis — There was a prominent abscess in the psoas muscle of the right side. The opening of the abscess revealed a large amount of pus. There were lesions of purulent endometritis as well as vaginitis.

The brain, with the exception of an excess of fluid in the fourth ventricle, was normal. Cause of death — Tubercular peritonitis.

CASE II. — A male patient aged forty years, admitted to the medical wards of the Philadelphia Hospital, suffering with chronic parenchymatous nephritis. This disease was complicated by pleural effusion on the left side. Under treatment this effusion was absorbed, but within two months he developed symptoms of peritonitis, and died of this complication.

*Autopsy.* Kidneys revealed the changes of chronic parenchymatous nephritis. Lungs, structure normal. The visceral and costal pleura on the left side adherent. Examination of the abdominal cavity reduplicated the appearances of the previously related case in so far as the peritoneal surfaces were concerned, and also the condition of the spleen and intestines. The inferior surface of the diaphragm was more thickly studded than elsewhere with minute nodules of tuberculous nature.

The suggestion of peritoneal infection through transference of material from the remains of the pleural inflammation seemed the most natural inference, especially when we recollect the free inoculation of the peritoneal and diaphragmatic lymphatic system with the pleural lymphatic channels.

CASE III. — Edward C., aged fifty. *Autopsy.* External appearances. Middle-sized, much emaciated man. Subcutaneous adipose tissue wasted.

Thorax — The lungs were somewhat swollen from hypostatic congestion. On section both lungs showed a pronounced tubercular broncho-pneumonia. The left lobe was riddled throughout with tubercles, and pneumonic foci; but no cheesy foci nor cavities. The right lung was similarly affected, but in a higher degree, and showed a cavity in the upper lobe near apex, which communicated with several smaller cavities around it. There was also a scar at apex of right lung indicating an old healed cavity. The bronchial glands were all enlarged and somewhat cheesy.

Heart — Was comparatively small in dimensions. Pericardium normal. The heart muscles, valves, and orifices normal. Large ante-mortem clot on right side. Mediastinal glands enlarged, and some of them calcified. In the group of mediastinal glands and encapsulated in the connective tissue on the right side was found a mink-ball (rifle); no injury to the lungs could be discovered, but the connective tissue in the mediastinum in this locality showed the scar tissue riddled by tubercles. Subsequent examination showed that the ball from the rifle (ball received twenty-two years ago) had entered at a point an inch and a half within the right nipple, slightly above the mammary line, and must have passed through the right lung to reach locality where found, although no scar could be discovered in the lung.

Abdomen—Peritoneum, normal. The lymphatic glands somewhat enlarged. The liver was of normal size, in second stage of fatty infiltration. Kidneys and supra-renal bodies normal. Spleen atrophied. Rest of organs normal.

It is a reasonable hypothesis that the phthisis in this case had a traumatic origin.

In conclusion it would appear to the writer that the mass of observations already made and constantly increasing demonstrate beyond question the very constant presence of a peculiar organism in tuberculous processes. Yet at the same time there was a certain nodular and cheesy process, undoubtedly tuberculous, in which the organism has not been formed. Probably some of these failures are traceable to imperfection in the method of search for it, but other cases are inexplicable on this ground. It seems probable that certain local inflammations, or irritants, can give rise to tubercular and cheesy tubercular non-specific (in the sense of organisms present) products quite local in character. When these lesions are diffused throughout the body, their diffusion is evidently governed by lymphatic circulation which may permit transference of irritant materials from the site of the primary inflammation to a new situation.

The bacterium on the contrary is capable of developing a tubercular specific process over the entire system, and researches seem to warrant us in designating this process as a specific tuberculosis.

Thus considered, the bacillus tuberculosis becomes one of the causes of tubercular inflammation. The question of the frequency of its operation is still unsettled, but side by side is possible the non-specific (in sense of the presence and aetiological relation of organism) inflammatory nodule, which is subject to similar degenerative processes as the so-called specific nodule. Were this Society a clinical body, very weighty clinical evidence, it seems to the writer, could be adduced to defend the above statements.

DR. SHAKL-SPEARCE said that no examination for the tubercle bacillus had been made. He thought, therefore, that neither of the three cases as they stand could, with our present knowledge, be considered to be of such undoubted significance as to warrant the claim that they are representative of a class of tuberculosis in men without the presence of the tubercle bacillus. In the mimic-ball case, too much time had elapsed, namely, twenty years, in view of the fact that experimental investigation seems to show that only a short time, at the shortest two weeks, is required for the development of artificial or inoculated tuberculosis. He thought, therefore, that we were hardly justified by such testimony as presented by these three cases in assuming, in the face of positive evidence of experiments, that there was a tuberculosis without bacilli. With regard to one of the abdominal cases, it may be remarked that there are cases on record where abdominal serous tuberculosis seems to have arisen by the passage of the virus along the Fallopian tubes.

DR. FOREMAN said that he plainly recalled the mimic-ball case, and that examinations of the sputum during life, and of scrapings of the lung postmortem, failed to reveal bacilli; at least any

which gave a typical reaction. DR. BRUEN desired to say in conclusion that no one was in a position to affirm the positive aetiology of tuberculosis; but the two cases of abdominal tuberculosis might inferentially be considered instances of non-specific inflammatory tubercular disease rather than specific.

**HYPERTROPHY OF PROSTATIC GLAND; CHRONIC CYSTITIS; CYSTIC AND CIRRHOTIC KIDNEYS; DEATH FROM EXHAUSTION.**

J. H. MUSSER, M.D. Mr. C., in good health until 1879. Then he began to suffer from pain at the neck of the bladder, with frequent micturition. From this time until his death he suffered from constant pain and irritable bladder, with recurring attacks of cystitis. During the attacks of cystitis the urine presented the usual changes of that disease. Two or three times in the course of the disease he passed a little blood. After a year's illness catheterization, which had to be performed occasionally, became the rule. On account of the pain morphia had to be given in increasing doses until death. The combined influence of his depressing disease and the morphia habit rendered Mr. C. unfit for any duties, the nutritive processes failed, and death resulted in February, 1884, from exhaustion.

On examination eighteen hours after death, rigor mortis was well marked, the body was emaciated, the face sallow in appearance; abdomen alone examined. The stomach and intestines presented the usual appearances found when death occurred from long-continued exhaustion. The kidneys were granular in appearance and very hard; the capsules were adherent, the cortical portions contracted. On the surface numerous small cysts were seen in both organs. They were not weighed, but both were atrophied. The liver was fatty; the lumbar lymphatic and mesenteric glands normal; the bladder was small and its walls much thickened and somewhat ribbed. At the base the mucous membrane was congested but not ulcerated. The prostate was much enlarged, very hard, and encrusted on the cavity of the bladder.

The interest of the case centred in the microscopical examination of the prostate. Ten years previous to the present illness, Dr. G. removed a small tumor, probably a fibroid, from the patient's head, while shortly afterward a persistent tendency to ulceration on the bone, recurring for a year, was only checked by a frequent application of nitrate of silver. Then there was a marked tendency to carcinoma in his family, with other evidence, that of his sister's history, she having had mammary carcinoma. Sections of the tumor showed the histological appearance of a chronic inflammation, with hypertrophy of the gland.

**TUMOR OF BLADDER; ENLARGED THIRD LOBE OF THE PROSTATE GLAND; RETENTION OF URINE; FALSE PASSAGE MADE BY SOFT CATHETER; SEPTIC FEVER; DEATH FROM EXHAUSTION.**

J. H. MUSSER, M.D. J. M., aged eighty-four, in early life unusually robust and active, in his calling a gardener. The latter ten years of his life have been sedentary, chiefly on account of a large leg ulcer and varicose veins. Moderately using alcoholic stimulants, he

smoked to excess. Never confined to bed from any illness. Family history good. Six months previous to coming under my care M. experienced difficulty in micturition. This gradually increased, until finally the effort to relieve his bladder had to be continued half an hour before being successful. I saw him the fifth day of complete retention of urine. After some difficulty I passed a soft catheter, and drew off about half the contents of the bladder, this organ having reached to the umbilicus. The operation had to be repeated twice a day until his death. It was noticed that the instrument twisted in its course. For one week chills and irregular fever followed the passage of the catheter. Death took place from exhaustion three weeks after the retention took place. It may be noted that in the rectum, by the fingers, a growth was discovered corresponding to the prostate gland. There never was any vesical hemorrhage.

*Autopsy.* Heart, liver, kidneys, and bladder alone examined. The rigor mortis was marked, the body not emaciated. The man was very large, and yet his heart was unusually small, especially when the condition of the kidneys is taken into consideration. They were cystic, and the seat of interstitial inflammation. Neither organs were weighed, and they were not allowed to be removed. The liver was fatty. The bladder was removed for examination. It was much enlarged, its walls thin and markedly "ribbed"; its mucous membrane not inflamed. In the trigone corresponding to the middle lobe of the prostate, a soft tumor, with a flat base and pointed apex, was seen. It grew directly into mouth of the ureter, completely occluding it. It was very red, but not ulcerated. The catheter had passed through the floor of the urethra half an inch from the vesical terminus and emerged in the bladder to the right of the base of the tumor. I have purposely not made any sections, as I desired to show the growth in its entirety. I suggest its reference to the committee on morbid growths.

REPORT OF THE COMMITTEE ON MORBID GROWTHS  
ON DR. MUSSIE'S SPECIMEN OF TUMOR OF THE  
BLADDER, PRESENTED AT THE MEETING OF NOV-  
EMBER 13, 1881.

(The notes of the cases having been mislaid, they were read at the meeting of December 11, 1881.)

"Your committee reports that this specimen is a hypertrophy of the third lobe of the prostate gland."

SARCOMA OF SKIN; SECONDARY SARCOMA OF LIVER;  
OVARIAN TUMOR; RAPID DEVELOPMENT OF HEPATIC  
SYMPTOMS; DEATH FROM EXHAUSTION.

K. G. Sim, white, single, aged twenty-eight, housekeeper, good habits. Family history good. No previous illness. Under care of Dr. Ludlow in Presbyterian Hospital. Health good until five weeks ago. She then experienced an attack of abdominal pain which occurred suddenly and, although relieved, continued with more or less severity until death. She noticed one week after this accident a swelling below the ribs of the right side. During the two years previous to the development of these symptoms she had to micturate fre-

quently, but since then the urinary symptoms subsided.

On admission, November 22, 1883, the abdomen was distended from ascites and a tumor was noted in the epigastrium and right hypochondrium. The liver dullness extended from an inch below the nipple to six inches below the ribs in the nipple line. By palpation its outline could be defined at the umbilicus, and, on the right side, at the crest of the ilium. The surface of the liver appeared smooth, its border even; tenderness was marked. In addition oedema of the legs was very marked, the body was much emaciated, the countenance of a dusky hue, the conjunctiva slightly tinged with bile pigment.

Further, the murmur of mitral regurgitation was heard over the heart, the breathing was labored, and the lungs oedematous. Her temperature was normal.

Appetite poor, tongue heavily coated, bowels constipated; one passage showed the feces dark and hard. Urine albuminous, sp. gr. 1.010, light color. Death two days after admission from exhaustion and oedema of lungs.

Autopsy eight hours after death. Rigor mortis marked; trunk emaciated; abdomen distended, legs oedematous; face dusky and yellow-tinged. On section cavity of abdomen filled with bloody serum. Lungs oedematous. Heart small, left ventricular wall thickened, averaging half an inch. Mitral leaflets thickened and incompetent. Spleen enlarged twice its normal size, soft and pulpy. Kidneys cirrhotic, but not granular; congested. In the left iliac fossa a cyst found with dark-colored grumous fluid contents, lobulated and springing from left broad ligament. It was to the liver and a tumor of the groin, however, that I wish to call especial attention.

The liver was not weighed, but was about three times its normal size. Two large round yellow-white umbilicated masses were seen on the surface corresponding to the nipple line. On section they were soft, cream-colored, vascular at the periphery, the size of small oranges. Similar smaller masses were found scattered throughout the liver. The tissue of the liver between the masses was normal. The gall-bladder contained normal bile; the large bile-ducts were free and healthy.

In the right groin two flat wart-like growths, hard and pale, the size of hickory nuts, were seen, firmly connected with the subcutaneous tissues and inguinal glands. Rather than warty in appearance, they looked not unlike a mulberry imbedded in the skin, save in color. The glands of the corresponding groins were enlarged and matted together by a local inflammatory process.

Microscopical sections of the tumor of the skin and of the growths in the liver showed the appearance of an alveolar sarcoma; that of the skin developing from the adjacent connective tissues and being the primary growth in all probability. These sections were made by my student, Mr. Weaver, and the character of them confirmed by Dr. Formad.

I remark that the tumor of the skin was probably the primary growth, for on examining the cyst of the broad ligament, the left ovary could not be well

defined, but in its place a nodule was seen which might have been a sarcomatous ovary. The tissues were too much destroyed for microscopical examination.

DR. DAVIS considered that the point of origin was the most important question. He doubted whether it had really started from the skin. Most of the cases which he had seen had started from the connective tissue, that is, the deep fascia. The fact of the ready excision of Dr. Musser's tumor would go to prove that there was a pedicle deeper down, which might have been found if sought for.

DR. GUY HINSDALE presented a specimen of

COMPOUND FRACTURE OF LEG AND FOOT; AMPUTATION AFTER ONE YEAR; RECOVERY.

Wm. M., aged thirty-five, while at work in a mine was severely injured by a large quantity of coal which fell upon him, crushing his right ankle. The external and internal malleoli were broken, and the soft tissues considerably lacerated. The patient was then transported to the Pennsylvania Hospital, Philadelphia, and placed under the care of Dr. R. J. Levis, and at the patient's urgent request conservative treatment was adopted. Drainage was provided for by means of large incisions; sinuses formed, the joint became ankylosed, and dead bone was felt in every direction. After remaining eleven months in the hospital he was discharged. He was admitted to the Episcopal Hospital in November, 1882. Sinuses extended toward the joint and behind the calcaneum. The lower extremities of the tibia and fibula were necrosed. Several attacks of erysipelas delayed operative treatment, to which the patient had consented.

January 11, 1883, Dr. C. B. Nancrede amputated the leg at the upper third, making use of a short anterior and long posterior flap, catgut ligatures, and silver sutures. The operation was done with full antiseptic precautions. The spray was from a solution of acetate of alumina, equal to two and one-half per cent. of saturation. The instruments were kept in a two and one-half per cent. carbolic-acid solution. The wound was dressed with lint saturated with the acetate of alumina solution; over that was placed carbolicized gauze; then the Mackintosh, which was secured by a rubber band above, and by strips of plaster. Four dressings were made under the spray, and boracic-acid ointment was applied over the stump on the third and fourth dressings, which were about three days apart. In four weeks the patient was up in a chair. The most gratifying feature of the case was that at no time after the operation did the temperature rise above 98.5° F.

The specimen has been macerated, and shows the original fractures, with complete ankylosis of the joint. The fragment of the internal malleolus has disappeared. Above its site the bone is rough and carious. A broad osteophyte is situated on the inner side of the lower end of the bone. The tibia is firmly united to the astragalus, and also to the fibula. The latter bone was fractured one and a half inches from its lower extremity. The fragments are united by a small band of bone about one fifth the thickness of the shaft. The fragments

abut firmly against the tibia, the lower fragment resting under its articular surface, and being coössified with it. The upper fragment is also firmly united to the tibia. The scaphoid, cuboid, calcaneum, and astragalus are thoroughly coössified.

DR. DAVIS said that the case had already been under treatment for two weeks before admission to the Pennsylvania Hospital. It had been merely dressed with resin cerate, and the parts had become much swollen, and large quantities of pus exuding. After consultation Dr. Levis had attempted conservative treatment.

DR. NANCREDE explained his reasons for so severe a procedure as amputation, which briefly were the utter uselessness—nay worse, excessive painfulness—of the member when used, and the frequently recurring attacks of erysipelas after even the slightest probing or use. In view of this latter fact the admirable course pursued by the case under antiseptic treatment was eminently suggestive.

DR. J. H. MUSSER presented a specimen of Ulcerative Endocarditis, the notes of which will be shortly published.

DR. E. O. SHAKESPEARE presented several microscopic slides of the Cholera Bacillus sent him by Dr. Koch, the remarks upon which will be shortly published.

DR. A. S. ROBERTS presented two specimens of hip-joint disease, the notes of which are reserved for future publication.

The following report was read by the chairman of the committee:—

Report of the Committee on Morbid Growths on Dr. Fisher's specimen of Peritoneal New Growths, presented at the meeting of November 13, 1884: "Your committee reports that this specimen is one of peritoneal carcinoma, primary in the pancreas and thence spreading to the omentum and expressing itself as a miliary carcinosis."

## Recent Literature.

*A Pharmacopœia for the Treatment of Diseases of the Larynx, Pharynx, and Nasal Passages. With Remarks on the Selection of Remedies and Choice of Instruments, and on the Methods of making Local Applications.* By GEORGE MOREWOOD LEFFERTS, A.M., M.D., Clinical Professor of Laryngoscopy and Diseases of the Throat, College of Physicians and Surgeons, Medical Department of Columbia College, New York: G. P. Putnam's Sons. 1884.

This volume contains the formulæ of local applications used by the author in his treatment of the various affections of the larynx, pharynx, and nasal passages. Useful hints are offered to the student to aid him in his choice of remedies, and the remarks on the proper method of making applications to the various parts are clear and concise. The deductions in regard to the time-honored gargle are exposed. It is of no value when we wish to medicate parts situated posteriorly to the anterior pillars of the fauces, and contra-indicated in all cases where the necessary movements of the parts in the act are painful. Its employment, therefore, is a restricted one, and has been superseded by the

direct application of the medicated solution in the form of spray. The galvano-cautery is recognized as an efficient agent in destroying redundant tissue in the nose and larynx, but the author wisely points out that the same results, in the majority of cases, may be obtained with less heroic means. In the nasal passages the destructive agents employed, in their order of merit, are: acidum nitricum, acidum aceticum glaciale, and acidum chromicum. Nitrate of silver as a destructive agent is strongly condemned, as it causes but a superficial slough, and owing to its stimulating qualities it excites cell proliferation, and produces structural changes that are not desirable. Considering the author's objections to its use in the nose and his reasons therefor, it is not quite clear why, in another part of his book, he should place the same caustic at the head of his list, and recommend it to destroy the base of laryngeal growths after their removal by forceps or otherwise.

The muriate of cocaine was not known to us until within a few days after this book issued from the press. With a chapter added on this most important drug of all to laryngologists the book will be as complete as a work of the kind need be. 11.

*Elements of Surgical Diagnosis.* By A. PEARCE GOULD, M.S., M.B. Lond., F.R.C.S. Eng. Cassell & Co., Limited. 1884.

The task of the reviewer becomes a pleasant one when he finds so much to praise and so little to criticize, as is the case in this little manual.

Mr. Gould touches the secret of good surgical instruction when he says: "I would urge upon the student the importance of grasping the fact that the *principles of diagnosis* are of more value and importance than any given application of them, and that he should endeavor always to look through and behind the application to the principle itself. In other words, the knowledge of *why* certain signs or symptoms justify or compel a given diagnosis is the key to correct diagnosis, and is the essential point for students to grasp."

The line of teaching indicated in this paragraph is most successfully followed, and the student is instructed in the methods of investigation and taught how to see, instead of being, as is so generally the case in textbooks, presented with tables of symptoms which are too often forgotten or but half remembered when the occasion for their use arrives.

Morbid appearances and deformities are for the most part clearly described, and Mr. Gould does not allow his reader to rest satisfied when he has arrived at the name of the affection under consideration, but goes on to show how to discover its relations to the parts about, and urges the importance of investigating also its effect upon the system at large.

The book is of convenient size and the print is excellent, making it a matter of wonder that so much information can be put legibly in so small a space. No beginner who studies this manual can fail to get from it much help in forming sound surgical habits, and to a practitioner in the country it would be a valuable saddle-bag companion.

*The Diagnosis and Treatment of Chronic Nasal Catarrh. Three Clinical Lectures delivered at the College of Physicians and Surgeons, New York.* By GEORGE MOREWOOD LEFFERTS, A.M., M.D., Professor of Laryngoscopy and Diseases of the Throat in the College of Physicians, etc. Reprinted from the *Medical News* of Philadelphia, April 26 and May 3, 1884, and from *American Clinical Lectures*, vol. ii., No. 6. St. Louis: Lambert & Co. 1884.

The origin and scope of this little book are fully set forth in the title. It is clear, concise, accurate, and readable.

*The Elements of Physiological Physics.* By J. MCGREGOR-ROBERTSON. Philadelphia: Henry C. Lea's Son & Co. 1884. Sm. 8vo. pp. xii., 528. [One of the Manuals for Students of Medicine.]

*A Textbook of the Principles of Physics.* By A. DANIELL. London: Macmillan & Co. 1884. 8vo. pp. xx., 653.

These two books are prepared by instructors in the medical schools of Glasgow and Edinburgh, and thus address themselves especially to students of medicine. They may justly claim their attention, but for different reasons. By an oversight a notice of them has been unduly delayed. The smaller book, that of McGregor-Robertson, deals with physics almost only in its application to experimental physiology. Indeed, it originated in courses explanatory of apparatus and methods of investigation. In consequence of this point of view much that is of the greatest importance to even an elementary knowledge of physics is omitted or most briefly treated. For what it professes to do the book is admirable, and can be heartily recommended. The numerous illustrations are, as a rule, clear and helpful; a few have suffered in the process of reduction or copying. Some of the practical applications concerning electricity and cathartics are incomplete or misleading. The metric system is not consistently used, and there are occasional linguistic irregularities, but these are insignificant trifles. A second edition will, we trust, mention some of the devices for short-circuiting either of the two induction currents. As a convenient aid to the memory of the galvanic current we would suggest the simple rule that in all common batteries is run down through the wire in an alphabetical sense.

Mr. Daniell's textbook is a much more important work on physics proper, and has already been very generally commended by those qualified to speak of its special merits. As the preface, however, distinctly mentions the author's desire to adapt it to the particular requirements of medical students, we may humbly venture to fear that he has not been altogether successful. The medical student whose thirst for knowledge is yet unquenched will find occasional applications to physiology, but they are not frequent enough to prevent the book from being an excellent work on physics, whose perusal will probably convince him that the subject is much larger than his entrance examination had led him to suppose. A second edition, which we trust will be called for at

no distant day, ought to contain a few of those tables of specific gravities, boiling points, etc., which are so dear to the beginner and useful for reference. The confusion of digestion with resorption, on page 252, will bear correction. In the "Bibliography" we miss both the *Methodik* of Cyon and that of Gscheidlen, although the latter is mentioned in the text. This valuable list of books would also be better were the date and edition mentioned, and if some brief hint of the character of the work were added. The apparatus ("strommühr") described on page 283 is not the invention of Viecordt, but of Ludwig, although it has some resemblance to the hæmodromometer of the former.

*Holden's Anatomy: A Manual of Dissection of the Human Body.* By LUTHER HOLDEN. Fifth edition. Edited by JOHN LANGTON. With over two hundred illustrations. Philadelphia: P. Blakiston, Son & Co. 1885.

Holden is deservedly a popular author with students. Though not very accurate, he is clear and practical, qualities which are readily recognized and highly valued. The new edition is a good deal larger than the preceding one; there are many new figures, and type, paper, and binding are excellent. The text, though essentially the same, shows many additions. The account of the surface of the brain is much more thorough than before. The book is a good one, as, indeed, it is hardly necessary to say after the editions it has passed through, but we must add that it is so good that we wish it were better. There are errors and inaccuracies that would not be found had the distinguished author given due attention to recent anatomical literature. The diagram of the Torcular Herophili is incorrect. The account of the tongue and the pharynx is unsatisfactory. Due stress is not laid on the fact that the posterior third of the dorsum of the tongue is practically vertical. We see no mention of the fossæ of Rosenmüller. The essentially adenoid nature of the tonsils is not insisted on. They are called glandular bodies, which is vague if not misleading. There is no proper account of the lymphoid tissue which forms an arch across the pharynx. The carotid is not so near the tonsil as is implied. The important insertion of the extensor communis digitorum into the base of the proximal phalanx is not mentioned. Figure 117 shows a median section of the pelvis in which the vagina is represented as a tube, an error which we must call inexcusable. We are astonished to find the statement that the round ligament of the hip is quite tight in the erect position. If the author has no confidence in the researches of Humphrey, Morris, and others, he should at least trephine the acetabulum and examine for himself. We can hardly suppose that he has never done so, yet we cannot conceive that he could make this statement if he had. These are defects that should not be found in a work by Professor Holden, but in justice to him we should say that it appears by the preface that the revision is by the editor, not the author. In spite of these blemishes there is much to praise, and we do not doubt the continued popularity of the work.

T. D.

## Medical and Surgical Journal.

THURSDAY, FEBRUARY 5, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by CUTPLES, UPHAM & Co., Boston. Price, 15 cents a number; \$5.00 a year, including postage.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUTPLES, UPHAM AND COMPANY,  
283 WASHINGTON STREET, BOSTON, MASS.

### THE MASSACHUSETTS HEALTH REPORT.<sup>1</sup>

We are glad to see again a report of the Massachusetts Health Department fully up to the standard of the former State Board of Health reports, both as regards the subject-matter and the ability with which the various topics have been treated.

Mr. J. C. Hoadley's paper on Tubular Wells for Domestic Water-Supply discusses the whole question of underground water-supply, with interesting graphic representations of some very useful experiments made to illustrate the phenomena of springs, subterranean streams, wide, diffused underground flow, and wells of every kind. These the writer shows to be subject to the law of gravitation, as their moving force, and to a retarding force caused by interstitial friction of the earth. The whole effect of reading Mr. Hoadley's excellent paper, which we would like to compel every selectman in the State to study, is to impress strongly upon the mind the importance of keeping all sources of contamination at a great distance from every well used for domestic purposes.

There are two papers on the sanitary condition of towns. Dr. Couch's report on Somerville, in continuation of the series begun with Dr. Pinkham's classic analysis of the vital problems of Lynn, is the record of an efficient and intelligent board of health and shows work worthy of imitation. In Nantucket, the old style of privy and cesspool admits of the escape of filth into the soil and stinks into the air. To avoid the high death-rate from infectious diseases, a pure water-supply and sewerage are recommended. Next to the little town of Florida, on the top of Hoosac Mountain, Nantucket has had the most virulent epidemic of diphtheria in our State.

A review for the year of weekly mortality reports from about one hundred cities and towns, representing nearly three-fourths of the population of the State, shows that the board has thereby increased local interest in accurate registration, and it has also improved medical diagnosis. It is unfortunate

<sup>1</sup> Fifth Annual Report of the State Board of Health, Lunacy, and Charity of Massachusetts. Supplement containing the Report and Papers on Public Health. Boston: Wright & Potter Printing Co., State Printers, 1884.

that our State registration could not be placed in the same able hands. But, instead of a State Board of Health, there is a board of health, lunacy, and charity, and the greatest of these is charity.

Nearly a third of the volume is devoted to the reports of inspection and analysis of food, including milk and drugs. Prof. E. S. Wood gives some admirable directions for methods of analysis. In 96 samples of milk he found 11 up to the standard of the law of 1880 (13 per cent. solid), 25 below 10 per cent. of solid, and 5 below 9 per cent. Of 7 samples of cheese, said to have produced poisonous symptoms, the results of examination were negative, owing to an imperfect knowledge of the nature of the poison. Four samples of butter out of 21 were condemned, although it was thought probable that several others were more or less adulterated with oleomargarine. Of 205 samples of spices, 135 were adulterated. In coffee 39 out of 40 were pure, 1 being adulterated with chicory. No foreign leaves were found in 15 specimens of tea; the examination of the ash showed one (green) to be adulterated. Of 5 samples of cocoa and chocolate and 2 of glucose, all were found pure. Of 3 samples of honey, 2 were chiefly glucose. There was considerable paraffine in 1 sample of beeswax. In 4 samples of cheap confectionery there was considerable starch and glucose but no injurious ingredient. Of 6 samples of granulated sugar, 5 were pure and 1 contained glucose; 6 of granulated sugar were pure, and 1 of yellow sugar had but 2.8 per cent. sugar. Of 18 samples of syrup, 16 were good, 1 was wholly glucose, and 1 (maple syrup) was largely adulterated with cane-sugar. Of 22 spurious lots of olive oil out of 49 examined, there were probably none that were not simply cottonseed oil. Of 17 samples of vinegar, 3 were condemned. In pickles 1 of 7 was soft and unfit to eat, but no injurious substances were found; many were undoubtedly more or less watered. In 10 samples of bread, no adulteration was found but all contained more water than is allowed by Wanklyn's standard (34 per cent.). In 17 specimens of wheaten flour and 29 of cornstarch, cornmeal, rye flour, rye-meal, barley, oatmeal, sago, and tapioca, there was no impurity. In 12 baking-powders no alum or deleterious substance was found. In 67 samples of cream of tartar, 20 were adulterated. Two bottles of wine were found watered and plastered. Four of 5 boxes of sardines were acknowledged to be herrings in cottonseed oil. Dr. Charles Harrington found that of 241 samples of milk 77.45 per cent. were below a standard of 13 per cent. solid, and 71.37 per cent. below a standard of 12.5 per cent, the principal methods of adulteration being the abstraction of cream and addition of water. Professor Goessmann, of Amherst, found in 79 samples an average of 12.92 per cent. solid: only 2 fell below 11 per cent. In one farm the milk was found to contain 13 per cent. solid, the same milk in the hands of a milkman 11.37 per cent. and when

it had got to the retail grocer 9.84 per cent.; showing additions of respectively 15 per cent. and 25 per cent. water. There is no statement of the cases in which there were prosecutions.

Dr. B. F. Davenport, the analyst of drugs, examined 680 samples of pharmacopoeial drugs and 8 of proprietary cough syrups. He has acted as expert for the board in seven prosecutions for violation of the adulteration act, in all of which the fact of an adulteration was proved, although in two cases the defendant escaped being held therefor.

In continuation of their investigations regarding trichinae, the board reports four cases of trichinosis, not fatal, in Brockton. Of 500 hogs examined 10 (or 2 per cent.) contained trichinae. The usual precaution against infection from trichinous pork is given, namely, thorough cooking of the meat.

Prof. E. S. Wood contributes an exhaustive article on Arsenic as a Domestic Poison, which seems to leave nothing to subsequent investigations. As the principal sources of domestic arsenical poisoning he mentions wall-papers and other papers, the most dangerous of which are the glazed papers used for wrapping confectionery; for the use of children in Kindergarten schools; for theatre and concert tickets; for the manufacture of playing-cards; for covering paper boxes which are often used for containing confectionery; clothing and other textile fabrics, such as cretonnes for covering furniture, for lambrequins—and even linen glaze has been found to contain arsenic; artificial flowers and leaves, which are sometimes worn in contact with the skin, in which case they are sure to produce a troublesome eruption; children's toys are frequently colored with arsenical pigments; articles of food or drink may sometimes contain arsenic in small amount, such as confectionery colored with arsenical fuchsine or arsenite of copper, or red wines and syrups artificially colored with an arsenical red pigment. Green wall-papers have been so long suspected that the green colors used now are for the most part mixtures of non-arsenical blue and yellow pigments. Red and blue papers are arsenical more frequently than green. Papers of any shade and of any color may be arsenical, and there is absolutely nothing in the appearance of a paper by which an opinion may be formed as to its containing arsenic or not. In a few instances, of different rolls of what appears to be the same paper, the pattern and the shades of color being precisely the same, so far as could be seen, one roll contained arsenic and another not, the pigment of the two rolls coming from different lots, one pure and the other arsenical. In the case of arsenic found in the white groundwork of paper intended for a nursery, it was thought probable that arsenic was added to the paste or size with which the pigment was made to adhere to the paper. Acute arsenical poisoning arises most often from the careless use, especially by children, of various poisons prepared

in various ways for the destruction of insects. Professor Wood details the symptoms of arsenical poisoning with forty-three cases as illustrations. He gives thirty-four samples of papers and two of cloths.

The paper, a model sanitary essay, closes with a description of the most approved tests for arsenic and a summary of the legislation of different countries on the subject.

Of 295 cities and towns replying to the circulars of the board, 147 have independent boards of health; in 148, including two cities, the local officials constitute the board of health. There were no complaints during the year (1883) of noxious trades under the law, and only twenty-one cases of small-pox (with four deaths) were reported. Some charcoal kilns in Charlemont were investigated without any very definite result as to the effect of the smoke on health.

#### EXTRAVAGANCE IN THE USE OF ETHER.

WE published last week an article on the administration of ether and a discussion on the paper which ought to furnish our readers with food for reflection. The discussion was confined, more closely than such discussions usually are, to a single point in a very wide subject—the proper method of giving ether in perfectly normal cases; and the point of the paper, if it can be summarized in a single sentence, would, we take it, be expressed as follows: Gentleness and tact in administration will shorten the stage of excitement, lessen the necessity for forcible restraint, render the process of inducing anesthesia easier and more agreeable alike to patient and physician, and greatly reduce the present reckless waste of the drug.

The opportunity to say a word upon the point of extravagance in the use of the drug is too good to be lost. The waste of ether, so common wherever this anæsthetic is used, has greater importance than is usually accorded to it. The great bulk of the drug usually required is a bar to its universal adoption. The amount which a man in civil practice must carry with him is quite a burden to one accustomed to the small amount of chloroform needed to obtain the same result, and it makes its use in army practice almost, if not quite, an impossibility. The use of chloroform in the army maintains in our midst an intelligent minority who are taught to use the more hazardous anæsthetic.

We are far from wishing to see economy carried to the point of niggardliness or to see patients deprived of the benefits of a free anæsthesia, but the vapor which announces the presence of a surgeon in the neighborhood to his brother practitioner who happens to enter the same street is certainly superfluous; when it causes the fire in an air-tight stove in the same room to burn with unwonted rapidity, it approaches the limit of safety.

Whether the quantity required can be reduced to so small a bulk as to compare favorably with chloroform for army use is extremely doubtful, but it can be greatly reduced from its present waste to respectable proportions; and those interested in extending its use and desirous of seeing it supplant entirely the more dangerous chloroform should bear in mind that any diminution in the amount necessary for anæsthesia favors its more extended use.

#### PREPARATION AGAINST CHOLERA.

OUR Atlantic seaboard cities are, some of them, taking timely steps to prepare, as far as may be, against the appearance of cholera on our shores with the return of warm weather. In New York a "Sanitary Protective League" has been organized for the purpose of guarding the city against a possible epidemic of cholera in the spring, at the suggestion of Mr. Charles F. Wingate, a prominent sanitary engineer, and a member of the Tenement-House Commission appointed by the Legislature. At a preliminary meeting, at which over fifty gentlemen were present, it was decided to call a public meeting, at Chickering Hall, and a pledge was adopted which requires the members of the league to sustain and stimulate the health authorities in their official work, to look after the sanitary condition of their own homes, and to secure the safety of employees and dependents.

In speaking of the matter, Mr. Wingate said: "Our idea is to unite all existing sanitary societies in a league to protect the city against cholera. There are several such societies, including the Ladies' Health Protective Association, the Hebrew Sanitary Society, the Sanitary Committee of the State Charities Aid Association, and others, and we shall group all the members together and then divide them up into local committees, whose duty it shall be to act as investigators of the condition of their several districts and report to a general committee any facts which may come to their knowledge regarding sanitary defects. The general committee will investigate these and report them to the Board of Health; when, if it is found that the board has no power to take action in any specific case, the committee will take proper measures itself. The money to do the work has already been pledged, so that no pecuniary responsibility will attach to the members of the league."

Such a league will, no doubt, be of considerable service in supplementing the work of the Board of Health, and, as the management of the Board is certainly less efficient at present than it was under the direction of Professor Chandler, it is to be hoped that it will have the further good effect of spurring on the sanitary authorities to a more thorough performance of their duty.

In Boston, a meeting of leading physicians and

sanitary engineers was lately called by the Mayor at his office, to consult with the Board of Health as to what steps should be taken to prepare for any possible emergency. The discussion which took place resulted in the appointment, by His Honor, of an advisory committee, consisting of nine prominent physicians of the city.

A Board of Health at such a time, however well disposed, needs, and should have, moral, legal, and financial support to an unusual degree, and such a committee may be very serviceable in insisting upon such support.

#### ANOTHER HEALTH BILL BEFORE CONGRESS.

MR. PALMER, on January 9, 1885, introduced a bill in the United States Senate, which has the title of a "bill to prevent the introduction and diffusion of contagious and infectious diseases in the United States," and which has the following provisions in its various sections, namely:—

Sections 1, 2, and 3, establish a Bureau of Public Health in the Treasury Department, charged with the execution of all laws passed by Congress relating to quarantine and the public health, and with the framing and execution of sanitary regulations. The chief officer of the Bureau is to be designated the Commissioner of Public Health, and to be under the general supervision of the Secretary of the Treasury. He is to hold office for five years and to receive an annual salary of \$4,500, and actual necessary traveling expenses.

Section 4 gives him the power of appointing, by and with the advice and consent of the Senate, seven superintendents of external and internal quarantine, embracing both infected persons and infected or adulterated goods, for certain defined districts. Their tenure of office to be the same as that of the Commissioner of Public Health, and their compensation to be \$3,600 per annum and necessary traveling expenses.

Section 5 provides for the framing by the Commissioner and his superintendents of a code of regulations for the conduct of the external and internal quarantine of the United States, solely for the protection of the people against contagious and infectious diseases, and against the dangers to life and health from poisonously adulterated goods for the use of the people. Such regulations shall conform, as far as practicable, to the local quarantine regulations in the several States. It shall be the duty of the Bureau of Public Health to supplement, and not to antagonize, the efforts of State and municipal boards of health in the work of sanitation. Such regulations may embrace provisions for obtaining, in connection with the consular service of the United States, special information concerning the shipment to this country of infected persons and of infected or poisoned goods, and for the

arrest of the same before landing; such regulations may also contain proper provisions for the detention and disinfection of infected persons and goods in transit from one State to another, and for the destruction of goods infected and poisoned to such a degree that no reasonable process of purification can make the same safe. Such regulations shall be approved by the Secretary of the Treasury, the Attorney-General, and the President, and also by the Secretary of State, so far as any provisions looking to the coöperation of foreign consuls are concerned, before the same shall become of any validity; but after such approval, and after official publication, they shall have the force of law, for the violation of which the proper Federal courts shall take cognizance.

Section 6 appoints an inspector of the ventilation, draining, and plumbing of all buildings belonging to the United States.

Section 7 provides for a chief clerk who shall act as Deputy, or as head of the Bureau, in case of removal or death of the Commissioner, until the vacancy be filled.

Section 8 provides for a public analyst, who shall make or superintend chemical analyses and microscopical examinations of all substances submitted to him for such purpose by the Commissioner of Public Health, and prepare full reports of the same. He shall be provided with a proper laboratory, apparatus, and instruments for doing his work well by the Secretary of the Treasury.

Section 9 provides that the Commissioner of Public Health and the Surgeon-General of the Army shall prepare a code of proper regulations for the better sanitation of the Army of the United States; the same to be done with the Surgeon-General of the Navy; with the Commissioner of Education for the better sanitation of all schools within the jurisdiction of the United States; with the Surgeon-General of the Marine-Hospital Service; for the better sanitation of merchant-vessels sailing under the flag of the United States, any vessels neglecting or refusing to comply to forfeit their right of registration; with the Commissioner of Agriculture for the better sanitary transportation from State to State of animals designed for the food of man; and with the President of the American Medical Association for the practice of physic and surgery, and midwifery, in any place or territory under the jurisdiction of the United States. Such regulations shall not include the Army, Navy, and Marine-Hospital medical services. For the service aforesaid the President of the American Medical Association is appointed, and shall receive such compensation therefor as may be agreed upon between him and the Commissioner of Public Health, with the approval of the Secretary of the Treasury.

Section 10. That all goods designed for food or drink of man, for wearing apparel, or for the furniture or decoration of habitations, so poisoned, by

adulteration, by coloring matter, or by any ingredient whatsoever, as to become demonstrably dangerous to human life or health, are declared to be contraband of commerce anywhere within the exclusive jurisdiction of the United States, and may be seized, detained, confiscated, or destroyed by the Commissioner of Public Health or his agents.

Section 11 provides for the detail of Army or Navy surgeons, to investigate special diseases or their causes, gives them no extra compensation, but allows for their actual traveling expenses, and requires from them full reports to the Commissioner of Public Health.

Section 12 provides for the temporary employment of competent physicians to aid the superintendents of quarantine during the invasion of an epidemic disease, and allows them compensation at the rate of \$10 per day during the time of actual service, and their actual and necessary traveling expenses.

Section 13 provides for the issue of a weekly bulletin for free distribution to all health boards, and to the press of the country, containing an abstract of such sanitary information as may be useful and interesting to the people. It also provides for a full annual report.

Section 14 provides pains and penalties for violation of the provisions of the act, by fines not less than \$100 nor more than \$1,000, or by imprisonment not less than 30 days nor more than one year, or by both fine and imprisonment.

Section 15 provides \$1,000 to defray expenses incurred in carrying out the provisions of the act.

Section 16 repeals all acts or parts of acts conflicting with the provisions of this act.

The introduction of bills seems to be as far as the present Congress is likely to go with legislation bearing on Public Health.

#### FALSE ECONOMY TOWARD THE NATIONAL LIBRARY AND MUSEUM.

RECENT advices from Washington inform us that the annual appropriation for the Medical Museum and Library in the army appropriation bill has been cut down from \$10,000 (\$5,000 for the Museum and \$5,000 for the Library) to \$5,000, which is certainly inadequate. This is the action of the House. It is expected that the Senate will restore the original figures, possibly it has already done so, and that a committee of the two houses will be necessary to make the two houses agree.

The only argument used against the first appropriation, in the same committee which passed the full amount last year, is, we understand, the fear that it will become a permanent appropriation.

We know of no way in which a more valuable precedent could be established, and we prefer to believe that it is rather an inconsiderate attempt at economy, and that a little further thought will

restore the appropriation to its original figures. Ten thousand dollars for the encouragement of medical study is not a large sum for a nation to expend whose income is we dare not think how many millions.

#### MEDICAL NOTES.

—Mayor O'Brien, of Boston, has appointed Drs. H. I. Bowditch, H. J. Bigelow, Francis Minot, R. M. Hodges, S. A. Green, J. G. Blake, W. L. Richardson, George B. Shattuck, and C. F. Folsom, an advisory committee in regard to the question of a possible epidemic of cholera next summer.

—We learn that a meeting of the citizens of East Boston was recently held with reference to the erection of a memorial to the late Dr. Thorndike, and that action was taken looking to the building of a public hall to be named after the deceased surgeon.

—The Cleveland, Ohio, Board of Education has issued an English version of the Brussels Manual for teachers, and adopted it for use in the public schools. This manual contains brief instructions as to the first symptoms of transmissible diseases.

—The fellows of the Royal College of Surgeons of Ireland have voted to concur with the Council of the College in having the charter altered so as to admit women to all diplomas of the college on terms equal with men.

#### WASHINGTON.<sup>1</sup>

—*Apothecaries in the Army and Navy Medical Service.*—Mr. Randall has introduced a bill (H. R. 8,017) into the House of Representatives, which provides: That the apothecaries of both army and navy shall receive a commission, those of the army to have the relative rank of a second lieutenant of infantry, those of the navy to have the relative rank of an ensign in the navy.

SECT. 2. That the said apothecaries of both army and navy shall not be in the line of promotion.

SECT. 3. That the said apothecaries of both army and navy shall receive the pay and emoluments of said grades in their respective branches of the service.

SECT. 4. That the said apothecaries of both army and navy shall not be entitled to any of the benefits that may be conferred by this act until they have passed a satisfactory examination in the following branches, namely: Elementary chemistry, materia medica, pharmacy, and botany.

SECT. 5. That each and every apothecary who shall be serving in such capacity at the time of the passage of this act shall be granted an examination, and if found proficient in the above-mentioned branches shall receive a commission in that branch of the service to which he may be attached.

<sup>1</sup> From our Special Correspondent.

— *The Garfield Memorial Hospital.* — Statements have been made respecting this hospital which go to show that it is about to be closed for lack of funds, but its financial condition is not so depressing as has been represented. It is true the hospital is in need of funds; but it has no debts. The institution was opened on May 30, and admission of patients began early in June. Since that time one hundred and fifteen patients have been cared for, of whom seventy-nine were occupants of free beds. A published statement says that Surgeon-General Murray gives his unqualified approval of the management; that the funds now in the treasury will support the hospital till June, and that the women of the "Ladies' Aid" in the Garfield Memorial Hospital are not discouraged, and feel that when the true condition of the hospital is known their appeal for contributions will meet with a generous response.

— *Bill for the Promotion of Anatomical Science, etc.* — On January 12th the House of Representatives passed a bill to the effect that any public officer or officers having lawful charge of, or control over, any hospital, prison, almshouse, jail, morgue, or asylum, within the District of Columbia, may deliver to the duly authorized agent of any medical college or colleges in the said District of Columbia the bodies of such deceased persons as are required to be buried at the public expense, said bodies to be distributed among the several colleges equitably, the number assigned to each being proportioned to that of its students; provided, however, that if the deceased person, during his last illness, of his own accord, requested to be buried, or if, within twenty-four hours after his death, any person claiming to be, and satisfying the authorities that he is, of kindred to the deceased, asks to have the body buried, or if such deceased person was a stranger or traveler who suddenly died, the body shall not be so delivered, but shall be buried.

SECT. 2. That every physician and surgeon, before receiving such dead body, shall give to the officers surrendering the same to him a sufficient bond that each body shall be used only for the promotion of anatomical and surgical knowledge within the District of Columbia, and that after having been so used the remains thereof shall be decently buried; and whosoever shall use such body or bodies for any purpose other than that aforesaid, or shall remove the same beyond the limits of the said District of Columbia, and whosoever shall sell or buy such body or bodies, or in any way traffic in the same, or who shall disturb or remove bodies from graves in which they have been buried, shall be deemed guilty of a misdemeanor, and shall on conviction be imprisoned for a term not exceeding three years, at hard labor, in the District (or city) jail.

The Committee on the District of Columbia, by whom the bill was recommended, recognize in their report that there are now several flourishing medical

schools in Washington well established, and one or more of them of long standing; that the laws of the District are very severe against the crime of grave-robbing. With such laws in operation, and such necessities for the schools of medicine, the authorities of the District are compelled either to wink at this offence or seriously to cripple, if not to destroy, the efficiency and success of these schools. Furthermore, the heads of these institutions, professors and students of science, are compelled to supply their admitted necessities by confederating with and employing professional grave-robbers, and constantly to incur the risk of detection and criminal prosecution; and it being known in a community that the trade of resurrecting bodies for dissection is a common one, kindred and friends are frequently tortured with anxiety lest the hand of the resurrectionist shall remove the bodies of their dead. This bill is intended to relieve from such fears, to do away with the necessity or temptation for violating the laws, and at the same time in an open and legal way to provide the requisite dissecting material for the study and advancement of anatomical science in the District. A careful comparison with the statutes of some of the States shows its provisions to be prudently and aptly framed, and intended to accomplish the purpose in view in a manner as little repellant to public sentiment and sensibility as practicable.

— *Dentistry in the District.* — The House of Representatives passed, on January 12th, a bill establishing a board of examiners whose business it shall be to issue certificates to all who shall be found competent to practise dentistry in the District of Columbia, and to require their proper registration. It imposes a fine for non-compliance with the provisions of the act of not less than \$50 nor more than \$200, and in default of its payment imprisonment of not less than thirty days nor more than ninety days; provided that nothing in the act shall be construed to prevent surgeons and physicians from extracting teeth and prescribing for, or treating, diseases of the mouth.

#### NEW YORK.

— A tenement-house commission appointed by the Legislature, which has for some time past been making investigations in the city, sent a preliminary report to Albany on the fifteenth of January, in which they made a number of recommendations in regard to tenement-houses, among which were the following: Abolish all vaults. Render all cellars impervious to water. No building to occupy more than sixty-five per cent. of a lot. That the hall of each tenement-house have free opening to light and air. All air-shafts to be open at top and bottom. All tenements to be inspected twice a year. — Some \$2,000 of the \$5,000 appropriated for the use of the commission still remains unexpended.

— Frankie Roberts, a "midget," on whom the the Caesarian operation was performed at Syracuse January 14th, died on the 16th.

— Dr. Richard C. Brandeis, professor of laryngology in the New York Polyclinic, disappeared from his home December 22d, and since then nothing has been heard of him. At first a reward of \$500 was offered for information concerning him, and now this amount has been increased to \$1,000. It is believed that a sudden development of mental aberration, of which there had previously been slight indications, caused him to wander away, and his friends fear that he has committed suicide.

— At a meeting of the Medico-Legal Society, held January 21st, at Hamilton Hall, Columbia College, an address was made by the retiring President, Clark Bell, Esq., and the installation of the officers elected at the preceding meeting, took place. Then, after listening to an address by the President-elect, Dr. R. Ogden Doremus, the members and a number of invited guests, adjourned to the Murray Hill Hotel, where the annual banquet of the society was partaken of.

## Correspondence.

### CIRCULAR PAVILION WARDS.

MR. EDITOR. — In your issue of January 8, 1885, appears a letter from London devoted chiefly to consideration of the circular-ward system in hospital construction. According to your correspondent's statements Dr. McKenna would seem to be entitled to the claim of priority in originating the system, while M. Baekelmans would be second and Professor Marshall third. The idea probably has occurred to many physicians and architects, though they may have neglected to publish it.

In January, 1882, I conceived the idea of circular wards from a study of the octagon pavilions accepted by the Johns Hopkins Hospital management, I had never heard of any such form being advocated, and it was not till last year, during a correspondence with Dr. Billings, U.S.A., that I learned of the Antwerp circular wards and of Professor Marshall's valuable paper.

From a review of the facts stated in the magnificent work of Mount and Snell on hospital construction and management, I should say that to M. Baekelmans is due the lion's share of credit for having given to the world, both theoretically and practically, the best form of building yet devised in which to treat the sick.

The wards in the Antwerp Civil Hospital and in the Miller Memorial Hospital, the only completed types at present, are by no means as perfect as the system admits. I am convinced that the full benefits can only be obtained in a pavilion of one story, where the automatic ventilation, characteristic of the domed circle, can be best effected. The circular ward surpasses all others in cheerfulness; it allows a flood of light to fall upon the patient from almost every direction; heat may be distributed equally in

all directions; in areage it far exceeds any other geometric form yet used; and with a ceiling in the form of a parabolic dome the cubic air-space is vastly increased and ventilation rendered almost automatic.

Now, as to expense, it is well known that the cost of a building bears a direct ratio to its wall length; therefore the circle having a minimum wall length for included areage should be naturally the cheapest structural form.

The circular ward that I designed in 1882 has an inside diameter of 67.5 feet, a total areage of 3,578.17 square feet, and an areage per bed of 147 feet. It accommodates twenty-four patients, who have each 2,125.05 cubic feet of air-space and 41.5 square feet of window. The ceiling is a parabolic dome, fourteen feet high at wall and eighteen feet high in centre. Through the centre of the ward passes a heating and ventilating shaft. The ward offices are detached by a lobby, and through them access is gained to the general corridor.

Yours truly,

A. C. HEFFENGER, M.D.,  
P. A. Surgeon, U.S.N.

## Miscellany.

### BRILLIANTS FROM THE EXAMINATION ROOM.

Is an amusing article in *All the Year Round* on examination blunders are several stories of a medical complexion. Those at the expense of medical students present a mixture of ignorance and of impudence. Among the latter are the following: A "badgering" examiner asked a student what means he would employ to induce copious perspiration in a patient, and got for answer: "I'd try to make him pass an examination before you, sir." The most frequently cited anecdote of this kind is that of the brusque examiner — said by some to have been Dr. Abernethy — who, losing patience with a student who had answered badly, exclaimed: "Perhaps you could tell me the names of the muscles I would put in action if I were to kick you?" "Undoubtedly, sir," came the prompt reply: "you would put into motion the flexors and extensors of my arm, for I should knock you down." Of a similar nature was the retort made to M. Lefebvre de Fourrey, a French examiner, celebrated not only for his learning but also for his severity and rudeness. He was examining a youth who though well up in his work hesitated over answering one of the questions put to him. Losing temper at this the examiner shouted to an attendant: "Bring a truss of hay for this young gentleman's breakfast." "Bring two," coolly added the examinee: "Monsieur and I will breakfast together."

Some of the best of the examination stories are those told of answers actually on record by her majesty's inspectors of schools, and other official persons, regarding especially the tests applied for the pupils' knowledge in the "specific subjects" in a public school within the metropolitan area. The specific subject selected was Physiology, and the answers, which are vouched for as genuine, will be interesting reading to those who are seeking to

popularize physiological and anatomical knowledge. To the question "Describe the process of digestion," one of the children "presented" in physiology replied in this wise:—

"Food is digested by the action of the lungs. Digestion is brought on by the lungs having something the matter with them. The food then passes through your windpipe to the pores, and thus passes off your body by evaporation, through a lot of little holes in your skin called capillaries. The food is nourished in the stomach. If you were to eat anything hard you would not be able to digest it and the consequence would be you would have indigestion. The gall-bladder throws off juice from the food which passes through it. We call the kidneys the bread-basket, because it is where all the bread goes to. They lay up concealed by the heart." Domestic economy, as nowadays taught to "children of the elementary school class," embraces a good deal of physiological knowledge or rather jargon. It is a subject which affords hosts of amusing answers. Thus, in reply to the question, "Why do we cook our food?" one fifth-standard girl gives the delightfully inconsequent reply: "Their of five ways of cooking potatoes. We should die if we eat our food roar." Another girl

writes: "The function of food is to do its proper work in the body. Its proper work is to well masticate the food, and it goes through without dropping, instead of being pushed down by the skin." A third pupil puts in her paper that "food digested is when we put it into our mouths, our teeth chews it, and our tongue roll it down into our body. We should not eat so much bone-making foods as flesh-forming and warmth-giving foods, for if we did we would have too many bones, and that would make us look funny."

On the subject of ventilation, one student informs us that a room should be kept at ninety in the winter by a fire, and in the summer by a thermometer; while a classmate writes: "A thermometer is an instrument used to let out the heat when it is going to be cold." Another girl sets down: "When roasting a piece of beef place it in front of a brisk fire, so as to congratulate the outside." But an answer perhaps best illustrating the jargon that comes of the cram system is the following: "Sugar is an amyloid, if you was to eat much sugar and nothing else you would not live because sugar has not got no carbon, hydrogen, oxygen, nitrogen. Potatoes is another amyloids."

## REPORTED MORTALITY FOR THE WEEK ENDING JANUARY 24, 1885.

Deaths reported 2,361: under five years of age, 890; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrheal diseases) 291, lung diseases 357, consumption 332, diphtheria and croup 149, scarlet fever 63, measles 50, whooping-cough 27, diarrheal diseases 26, typhoid fever 23, malarial fevers 17, puerperal fever 14, cerebro-spinal meningitis 12, erysipelas 7, gastric fever two, typhus fever one. From *measles*, New York 33, Philadelphia 9, Brooklyn 4, Chicago 2, Boston and Lowell one each. From *diphtheria*, New York 9, Boston 7, Chicago 4, Brooklyn 3, District of Columbia, Nashville, and New Bedford one each. From *typhoid fever*, Philadelphia 10, Chicago 4, New York 3, Brooklyn, Boston, New Haven, Lowell, Cambridge, and Somerville one each. From *malarial fevers*, New York 3, Brooklyn 5, Chicago 2, Baltimore and District of Columbia one each. From *puerperal fever*, Brooklyn 6, Chicago three, Boston two, Philadelphia, Baltimore, and Somerville one each. From *cerebro-spinal meningitis*, New York 7, Haverhill two, Chicago, Boston, and Springfield one each. From *erysipelas*, Boston two, New York, Brooklyn, Baltimore, District of Columbia, and Nashville one each. From *gastric fever*, Fall River two. From *typhus fever*, Brooklyn one.

In 105 cities and towns of Massachusetts furnished an estimated

population of 1,286,162 (estimated population of the State 1,955,100), the total death-rate for the week was 18.54 against 18.37 and 18.62 for the two preceding weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,906,446, for the week ending January 10th, the death-rate was 24.9. Deaths reported 4,255: infants under one year of age 813; acute diseases of the respiratory organs (London) 609, whooping-cough 91, measles 88, scarlet fever 51, diphtheria 42, fever 37, small-pox (London 34, Liverpool and Newcastle one each) 36. The death-rates ranged from 19.0 in Bolton to 36.0 in Cardiff; Birkenhead 26.3; Birmingham 23.7; Bradford 20.4; Brighton 19.1; Leeds 20.5; Leicester 31.0; Liverpool 27.5; London 25.0; Manchester 30.9; Nottingham 22.7; Sheffield 19.6; Sunderland 22.1. In Edinburgh 29.8; Dublin 31.2; Glasgow 35.6.

For the week ending January 3d, in the Swiss towns, there were 20 deaths from consumption, lung diseases 20, measles 7, diphtheria and croup 2, typhoid fever 2, small-pox one, scarlet fever one, whooping-cough one. The death-rates were: at Geneva 13.2; Zurich 11.8; Basle 14.7; Berne 18.9.

The meteorological record for the week ending January 24th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps:—

Date.	Barom-eter.	Thermometer.		Relative Humidity.		Direction of Wind.			Velocity of Wind.			State of Weather.			Rainfall.	
		Daily Mean.	Daily Mean.	Maximum.	Minimum.	7.23 A. M.	3.23 P. M.	11.23 P. M.	7.23 A. M.	3.23 P. M.	11.23 P. M.	7.23 A. M.	3.23 P. M.	11.23 P. M.	Duration, Hrs. & Mins.	Amount in Inches.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JANUARY 21, 1885, TO JANUARY 30, 1885.

WEISBERG, WARREN, major and surgeon. Granted leave of absence for one year on surgeon's certificate of disability, S. O. 20, A. G. O., January 21, 1885.

KIAN, J. R., first lieutenant and assistant surgeon. Ordered for duty in Department of Missouri. S. O. 23, A. G. O., January 25, 1885.

#### PROMOTIONS.

LIEUT.-COL. JOHN E. SIMMERS, surgeon, to be surgeon, with rank of colonel. January 9, 1885.

MAJOR JOSEPH R. SMITH, surgeon, to be surgeon, with rank of lieutenant-colonel. January 9, 1885.

CAPTAIN EGON A. KOEHLER, assistant surgeon, to be surgeon, with rank of major. January 9, 1885.

#### APPOINTMENT.

HENRY I. RAYMOND, to be assistant surgeon, with rank of first lieutenant. January 12, 1885.

#### SOCIETY NOTICE.

SUFFOLK DISTRICT MEDICAL SOCIETY. The Section for Clinical Medicine, Pathology, and Hygiene will meet at 19 Boylston Place on Wednesday, February 11, at 7.15 o'clock. Dr. J. Chester Morris, of Philadelphia, will read a paper on "The Milk-supply of Large Cities." Final Report of the Committee on "The Milk-supply of Boston." Members of the League of Physicians, Drs. Abbott and Walcott, of the Massachusetts State Board of Health, members of the Boston Board of Health, Prof. R. F. Day, captain, City Inspector of Milk, Dr. C. Harrington, of Harvard University, Dr. H. C. Haven, of the West End Nursery, members of the Milk Producers' Association, and others, are expected to take part in the discussion. All interested in the subject are cordially invited to be present. A collation of bread and milk will be served at the close of the meeting.

ALBERT N. BLOOM, M.D., Secretary.

GYNECOLOGICAL SOCIETY OF BOSTON.—The regular meeting of the Society will be held at No. 19 Boylston Place, on the second Thursday of February, at 7.30 P. M. A paper, communicated by Dr. H. G. Bigelow, of Washington, D. C., entitled "Conservation of Energy and Conservative Gynecology," will be read. Members will please notice the change in the hour of meeting.

H. J. HARRIMAN, M.D., Secretary.

DELEGATES and others purposing to attend the meeting of the American Medical Association at New Orleans, April 28th to May 1st, are informed that arrangements are being made for an excursion party with parlor and hotel cars. Particulars may be obtained by addressing

W. B. ATKINSON, M.D.,  
Secretary Am. Med. Association,  
1490 Pine St., Philadelphia.

ERRATUM.—In the announcement of deaths in JOURNAL of January 29th, for "Lewis" read Levi.

#### BOOKS AND PAMPHLETS RECEIVED.

Extensive Burn involving the Cavity of the Knee-joint. Read in the Section of Surgery at the Annual Meeting of the British Medical Association, by W. H. Daly, M.D., Pittsburgh, Penn., U. S. A. (Reprint.)

Address in Medicine delivered before the Medical Society of the State of Pennsylvania, by W. H. Daly, M.D., of Pittsburgh, at its Annual Meeting, held in Philadelphia, May, 1884.

Inflamed and Sensitive Teeth. By John T. Codman, D.M.D., Boston, Mass. Read before the New York Odontological Society, October 21, 1884. (Reprint.)

Transactions of the American Ophthalmological Society, Twentieth Annual Meeting, Catskill Mountains, 1884.

Nineteenth Report of the Board of Trustees of the Connecticut Hospital for the Insane, State of Connecticut, 1885.

Poliomyelitis Anterior in Adults. By Gustavus Eliot, A.M., M.D., of New Haven, Conn. (Reprint.)

Denison's Annual Climatic Map of the United States, Graphically illustrating Cloudiness, with Isotherms, Precipitation Lines, etc. By Charles Denison, A.M., M.D.

## Address.

VALEDICTORY ADDRESS.<sup>1</sup>

BY FORDYCE BARKER, M.D., LL.D. (EMIN.), THE RETIRING PRESIDENT.

FELLOWS OF THE ACADEMY.—In now closing my official relations with the Academy, it is both a pleasure and a duty to briefly recall the more prominent features in its history during the period of this connection. I will also venture to offer a few suggestions derived from my long experience in this position, as to some points relating to its future growth, its increasing usefulness, and its influence on the profession. As I know you will be impatient for the intellectual feast which is to follow in the address of my successor to this chair, I shall be as brief as is consistent with a clear statement of the points to which I think it desirable to ask your attention.

It has been my good fortune to hold this position when the profession was becoming more alive to the importance of this institution, and more and more ready to contribute material aid for its growth and support; at the same time there was a new development of mental activity in the profession, not only in this city, but all over the world, as demonstrated by great and important discoveries in science, and a wonderful increase in, and valuable additions to, medical literature.

As I have alluded to these facts more in detail in former addresses before the Academy, I will not detain you now by further allusion to them. I will only briefly refer to a few of the most notable events connected with the Academy during my administration.

First to be mentioned is this new and commodious hall, which could not then have been built except for the munificent donation of one noble benefactor, Dr. Abram DuBois, and the contribution to the full extent of their hard-earned means by many others. We are rapidly outgrowing our new hall, and must soon have another, as our library is now nearly filled. As I learn from Mr. Browne, our excellent assistant librarian, the Academy had, when this hall was built in 1879, about 9,000 volumes; it now has about 25,000 volumes and 15,000 pamphlets. Its circulating department has about 6,000 volumes, which our Fellows can take out of the library for consultation at home. In our journal room, open as is the library for all who may wish to read in our rooms, there are 225 medical journals in all languages in which there is to be found a medical literature.

The Academy is greatly indebted to Messrs. William Wood & Co., and D. Appleton & Co., for large donations of their new publications, and I believe to some foreign and other American medical publishers. We gratefully acknowledge the generosity of these gifts, and we feel assured that they were made from entirely generous motives. But we may be permitted to express the conviction that both publishers and authors will find it a wise business policy to place a copy of every new medical work in our library, as it has been estimated by a competent authority that one copy of every new

good book in this library will secure the sale of at least ten more. The library is visited, not only by the profession of this city, but by medical men from all parts of the country, who come to this great metropolis. They have seen in some medical journal a notice of a book, but have not remembered who were the publishers; in coming to our library they examine it to see if it is what they want.

The next notable event in the history of our Academy, since I have held this position, is its absorption of another very important organization, the Journal Association, which, to quote from a former address, "not only added largely to our library, but also to our moral and intellectual power."

The truth of history demands that the fact should be mentioned, that nearly two years ago the Academy passed through the segment of a cyclone, but like a good steamship, driven over a sandbank near a leeshore, with its engines temporarily disabled, it escaped being hogged, its seams were not opened, its barnacles have been scraped off, its bottom has been cleaned, and it has since gone on its voyage with favoring winds and fine weather. All who are familiar with its past history and who are unbiased by personal feeling or prejudice, must agree that the Academy has more nearly approached its avowed aims and its high purposes during the past year than in any former one since it was founded. It has had a larger increase of prominent men, and of young men of promise, than in any previous year since that in which it was organized, with the exception of the year when the Journal Association came into it. More than four times as many papers have been offered to me than there have been sessions to listen to them. As these sessions have been promised to previous applicants months before, very many of these papers have been withdrawn. I have afterward seen them not only in the medical journals of this city, but also in the journals of Philadelphia and Boston. It is bare justice for me to add that I have generally found them to be of such merit that I greatly regretted that the Academy could not have the credit of their first publication.

The papers which have been read at our meetings have been characterized by careful preparation, thorough research, original and often valuable hints as to pathological explanations and therapeutic indications.

Our discussions have been of such excellence that I am quite certain that every one carries away from our meetings either new suggestions or new information, which amply compensate for the evening passed in this hall.

In a scientific body like this, all discussions should express the results of mature inquiry, and a clear and forcible statement of the reasons which have led to positive practice. In some papers the novelty of opinions advocated and original methods of practice proposed, whether medical or surgical, may be so exclusively a matter of individual experience, that all discussion must be necessarily limited at first to inquiries and *a priori* objections, founded on anatomical, physiological, or pathological grounds. Papers of this class should be the subject of a most thorough and searching examination; for they

<sup>1</sup> Delivered before the New York Academy of Medicine, February 5, 1885.

may be either mischievous, and their effect for evil must be effectually exposed, or they may possess positive value which should lead to prompt acceptance and adoption.

To secure such discussion as will represent the most advanced knowledge of the Academy on any special topic, I have at our recent meetings adopted a plan first introduced by Dr. V. P. Gilney. Writers of papers have been requested to send, to a few of those whom they knew to have given special attention to their subjects, the points which it would suggest for discussion, printed on a small slip of paper, and especially asking those who held different or opposing views to take part in the discussion. They thus have time to arrange and formulate their knowledge and opinions, and the time of those present at the meeting is not wearily wasted in listening to crude, profitless, and digressive talk.

The reports of the Treasurers of the Academy and of the Board of Trustees have already been before the Academy. While its financial condition is now better than ever before, there still remains much to do. A few weeks since a Committee of Ways and Means was appointed, of which Dr. Gouverneur M. Smith is the chairman, to solicit contributions to pay off our only debt, a mortgage of five thousand dollars. They have worked with great zeal and enthusiasm, and the Fellows of the Academy have responded with self-sacrificing generosity; the necessary sum has not yet been wholly secured, but the prospect of soon accomplishing this is most encouraging. We particularly need money for preserving our library by bookbinding. It will be remembered that last year a generous sum was given for this purpose by a lady, who has in many instances shown that she is as warm a friend to the Academy, as she is conspicuous for her readiness to aid every good work by munificent support. Many of our Fellows have also most liberally added to the beauty of the library in this way, and have rendered great service in the preservation of our books in good condition, which otherwise would speedily deteriorate.

I have long contemplated offering some suggestions on the present occasion as to the wisdom of a change in our by-laws relative to the duties and functions of the sections. Only one of the sections, that of Obstetrics and Diseases of Women, has kept up an active organization, done excellent work, and made regular reports to the Academy, since my official connection with it. Two or three only of the other sections have reported their organization by the election of a chairman and secretary; and this has been all. Two have appointed a Fellow to read an original paper before the Academy, one of which, a most valuable paper, was read before us. The other I have never been able to get, and, as four years have now passed since that time, I do not think it very probable that it will ever come before the Academy.

The founders of the Academy did not contemplate making these sections independent societies for special work, but as contributing aids to the high aims of the central power. I had proposed to suggest such a modification of Article XVII., Section 2, as would assign to the sections functions similar to those of the Academy of Medicine of

Paris. But we have not the time now to consider the details of such a change, and I leave the matter for future consideration by the Academy and my honored successor.

Neither did the founders of the Academy intend to absorb or concentrate in itself all the scientific work of the profession in this city. The whole spirit of its high aims and purposes indicates that, on the contrary, they desired to stimulate and encourage such work in every feasible direction. I hope the time is not far distant when the Academy will be so well endowed that it may offer to all such societies, as the New York County Medical Society, the Pathological, the Obstetric, and the Surgical Societies, and the youngest of all, which has begun its career with excellent scientific work, the New York County Medical Association, a home for its meetings free from all expense.

Our standing committees have always faithfully discharged their important duties, with one exception, and that is the Committee on Medical Education, which has had little to do, and it has done just this and nothing more.

I may now be permitted to ask if the time has not come when it should be one of the most important and useful of all of our standing committees in carrying out one of the objects of the Academy as declared in our Constitution—"the elevation of the standard of medical education." How can this be best effected? is the question.

It seems to me that a way is now open for this committee to do effective work in this direction.

For years some of the medical profession in all parts of the country have been agitating the question of separating the licensing power to practice medicine from the teaching power.

It is a subject of great importance to the profession, to our medical schools, and equally so to the community. It must be met and settled in a way that will be most effective for good, but this cannot be done at once. There are two ways by which this can be accomplished, but each would require time.

One way involves the division of the profession into contending parties, each most zealous to carry its point; heated controversies, which always provoke personal feeling and personal antagonism; an appeal for action of societies; and a struggle for majority votes, not only in medical societies, but in securing legislative action,—all of which would undoubtedly affect injuriously our medical colleges and lower the profession in the estimation of the public. Any good secured would be at a great and unnecessary cost. The public cannot understand medical controversies except from what appears on the surface. A "doctors' quarrel" seems to the non-medical community like a fight between drunken men in the dark. The late Mr. Charles Dickens once related to me a story which he had heard of how Sidney Smith convulsed with laughter a dinner company at Holland House, by his description of a duel between two doctors. The mode of warfare was croton oil on the tips of their fingers, trying to rub each other's lips.

Now, this question is one which belongs to the domain of reason, and, let us hope, for the honor of the profession, that hereafter it will be confined

to the region of argument, and that in due time it will be settled to the satisfaction of all who are actuated by pure motives and a desire to secure the best results. At the last meeting of the Academy, some resolutions were offered; but by the courteous consent of my friends, the mover and seconder of the resolutions, they were laid on the table for future consideration. I therefore feel that I have now the floor, and venture to throw out a few suggestions as to the other method of meeting this question.

In order that the standpoint from which I look at this subject may be perfectly understood, I will briefly state a few propositions which seem to me common ground upon which we all stand and from which we must start.

Where charters for medical colleges can be easily obtained from State Legislatures, it is a duty which the profession owes to the public as well as to itself, to protect the community from ignorant, unprincipled practitioners of medicine, who not only swindle their victims, but jeopardize health and often sacrifice human life. This is a matter of great difficulty where each State is an independent sovereignty as to all such laws, where there is no central power to control action, and where personal freedom of opinion and conduct is zealously guarded as to everything which does not interfere with the rights of others, as regards health and property. The interests of the medical profession are so closely allied with the medical colleges that what affects detrimentally the one must reciprocally injure the other. The profession has a perfect right to supervise the methods and exercise a controlling influence over those who by law are permitted the privilege of giving a diploma, which is effectually a license to practise medicine.

All wise legislation must be based on a thorough knowledge of all the conditions which demand special law; it cannot be evolved from the inner consciousness of any one who has only the spirit, the zeal, and the genius of reform, but must be derived from the accumulated wisdom and experience of the past.

Mere examinations by a special board, who have had no previous training in this direction, no personal acquaintance with the mental characteristics, the habits of study, or the personal conduct of the candidate, would be as unsafe a test for admission to the profession as any objection that can be urged against the present system. Injustice would be done to some, while flippant readiness in reply, which can be easily attained by a quick, bright mind by a few weeks of cramming, without either solid acquirement or sound judgment, would always secure success.

The experience of all countries has demonstrated the necessity of examination by the teaching faculties and the wisdom of their assent to a license to practise. But in all other countries except this there is an additional protection to the profession and the public by the concurrence of another power.

In the Edinburgh University, and in some other medical institutions of Great Britain, this is vested in a special board of examiners. In France this is under the direct control of the government. The minister of public instruction has not only the

power of granting or withholding the diploma, but in addition, even in this so-called Republican government, he has the power of retiring any professor whose teaching is not abreast of the times. In Germany also, while the methods vary in different universities and in different constituent parts of the empire, it is yet under government control, which I believe is always exercised wisely.

Now I offer the suggestion that a committee of judicious, wise, and unprejudiced medical men, which would represent the best interests of the profession, the medical colleges, and the public, could frame a law, with the aid of competent legal advisers, which would combine the two methods, in accordance with the spirit of our Republican institutions and the sentiments of our epoch, and thus save the profession from unfortunate and heated controversies, and from crude, hasty, and ever-changing legislation.

Would not the demands of the most progressive members of the profession be satisfied if the Regents of the University were empowered by law to appoint the Committee on Education of the Academy of Medicine a supervisory Board of Examiners for the medical colleges of this city, whose duty should be to make an annual report, not only as to the examination for diplomas, but other details, as to the instruction and education of the student? This committee should be enlarged to the number of the principal departments of instruction, and should serve without pay—for there can be no doubt that the best men in the profession, who have the time, would esteem it a high honor to serve on such a committee.

For the medical colleges in other parts of the State, there would be no difficulty in devising a method by which the Regents would appoint men for the board of supervisory examiners, who would be most satisfactory to all. None except those who are well acquainted with the facts can appreciate the immense advance which the medical colleges of this city have made within the past quarter of a century in teaching and the increased facilities for acquiring a thorough education in all departments.

I have also great pleasure in referring to two other schools, the "Polyclinic" and the "Post-Graduate Medical School and Hospital," which have been doing a great work for the more thorough medical education of those who have diplomas, and thus necessarily for the "elevation of the profession" within the past three years. I do not believe that one in fifty of the profession of this city, has the least conception of what these schools are doing. If I expressed in moderate terms my estimation of the importance and value of their work to the profession of the country, I should be regarded by many as either carried away by my enthusiasm or prompted by personal considerations—so I will only say, Go and see for yourselves. Medical men who come to this city, and who always keep up their professional interest, should not fail to visit and see what clinical teaching and clinical opportunities are found here, with all the equipments for their utilization, and they will be well repaid for the time given up for this purpose. This system of special clinical improve-

ment originated in Germany, and nine or ten years ago I seized an opportunity to visit the most prominent of the Polyclinics in that country. Undoubtedly they have greatly advanced within this time, but I assert that then none that I visited were either in clinical advantages or clinical teaching on a level with our own at the present time.

I take the liberty of suggesting that it would be a wise and politic move for the medical colleges of this city, the "New York Polyclinic" and the "New York Post-Graduate Medical School and Hospital," to take the initiative and invite the Committee on Medical Education of the Academy of Medicine to visit these institutions, study their methods and their equipments, and report the result of their observations to the Academy at its annual meeting in January, 1886.

It must be obvious to all that this great improvement in medical education, far beyond the elementary teaching of former times, implies a corresponding elevation, not merely in the level of the average of the profession, but a still greater growth in the higher standards of medical science and literature. Thus the inquiry is naturally suggested, What is the future of this Academy, what is to be expected from it, and how is it to be placed on the high plane where it should stand in reference to the profession, not only of this city and of this country, but of the world? A wise forecast will early plan to secure a result which it desires to attain.

While our educational institutions are steadily improving their facilities for training the young men who are about to begin their career, and our Polyclinics and Post-Graduate Schools are more thoroughly preparing them for the higher grades of the profession, such an organization as our Academy of Medicine—in the great metropolis of the country—should be an ultimate centre, at which all those who have been long enough at work to find out their individual vocation should have every opportunity to carefully study all the literature of past ages, and make original investigations in every possible field of medical science which can add to its importance. All short of this will be just so far a failure of the true mission of the Academy.

Thus far, which is only a beginning, the Academy has done its duty, in bringing together most of the best men of the profession and making them acquainted with the special ability of each, in collecting a most creditable library for consultation, research, and circulation, and in stimulating and bringing out good literary and scientific work.

What the Academy requires in the future is:—

(1) A large fireproof building, with ample room for a library containing all the medical literature of past and coming times, and including (2) A large hall for its meetings, and others for smaller societies and committees. (3) A large room for a museum, illustrating physiological and pathological anthropology, and which should include a craniological series, a pathological series, and a series of sections and dissections, illustrating topographical human anatomy and a comparative anatomy series. (4) An anthropometric laboratory, provided with the best means of measuring human bodies, the faculties, and everything cognate to these subjects, and

which should include a set of psychometrical instruments and everything pertaining to the series. (5) A lecture hall, connecting with the laboratory and fully equipped with apparatus for lectures and demonstrations of all kinds. (6) It should also have a thoroughly educated and trained pathologist, who should, by means of an adequate salary paid by the Academy, be able to superintend all the scientific work and report on the specimens furnished to him; also a first-class mechanic, skilled in brass and glass work; and a good practical phonographer.

This is a broad scheme, which will require a very large endowment, but it is my firm conviction that it only outlines the future of the Academy, even if it demands a million of dollars. The liberality of New York is as boundless as its wealth, when convinced of the worthiness of its object. But large wealth is subjected to perpetual annoyance from solicitations and to criticism from those who have some pet end to promote, which they deem the most important above all others. This kind of discipline trains wealth to the exercise of discrimination and judgment, and besides it has its own convictions as to how its surplus can best be employed. The position of the possessors or representatives of great wealth in this country is peculiar and anomalous, and the thinking men of this class, and there are many, perfectly comprehend this.

There is no reason to suppose that there will be any exception in this country to the general experience of the world in the past, which is, that those who have but little or no property will greatly outnumber those of large wealth. Here lies the peculiarity and anomaly of wealth with us. Heretofore, property has protected itself through its representatives, by monopolizing or controlling the law-making and the law-administering power. With us the condition of affairs, if not actually reversed, has certainly been brought within the possibility, if not the calamity, of absolute reversal; inasmuch as through universal suffrage, untrammelled by conditions of property, and absolutely (in theory at least) free elections, the control of all law-making bodies and the appointment of all law administrations, has come to be possible with those "who have not" rather than "to those who have."

Property or its representatives, and more especially the representatives of very large wealth, are therefore exposed to dangers in the future with us through arbitrary or destructive legislation, which have not existed, or do not now exist, anywhere else. The possessors of great wealth, in virtue of their superior education and knowledge of the use of methods, may be able to guard themselves in the future as they have in the past, but this will turn on the fact whether the great majority of such have the clear perception of the future and the sagacity to avail themselves of the two strictly legitimate methods for protection open for adoption.

The first is to bring to the masses, in whom all political power rests, a full realization of the fact that nothing so undermines the property of a state, or so quickly impoverishes the people, through the arrest of industrial growth, as the impairment, or the menace of impairment, of the rights of property.

The second is, the demonstration by the posses-

sors of wealth, by liberal contributions to every object that can benefit humanity, relieve suffering, prolong and preserve human life, improve education, aid scientific investigation, and promote a higher development of art, that it is a greater boon to the masses than it is possible to secure by any other means, as the past history of the world illustrates.

We have abundant proof that this view has been adopted by many in this city. The foundations of the Astor Library and the Cooper Institute are a corroboration of this statement as regards the past. The splendid gift to the College of Physicians and Surgeons by Mr. W. H. Vanderbilt, the munificent endowment of the New York Cancer Hospital by Mr. John Jacob Astor, and the generous liberal contribution of Mr. Andrew Carnegie for a pathological laboratory in the Bellevue Hospital Medical College, are recent evidences of the correctness of my assertion. Such noble examples are sure to be emulated by many others in the future.

The wonderful growth and development of this country is unparalleled by anything in the history of the past, and it is certain to go on in even more rapid strides for years to come. Its educational and scientific institutions will be placed on a corresponding plane, as compared with other parts of the world, with its industrial, its financial, and its political relations.

There is another point worthy of remark. Men of wealth, in common with other men of intelligence, like those devoted to literature or science, have a desire to be remembered after death. They have a dread of having their names and the record of their lives pass into utter forgetfulness or oblivion. To avoid this, the resting-places of the dead are everywhere crowded with cenotaphs and memorials. This is strikingly manifested in some parts of the country by the most expensive monuments and mausoleums of modern times. They crowd each other in some of our cemeteries to such a degree that they lose all their individuality in their multiplicity, and the names which they are intended to keep alive are forgotten in the observations as to the comparative merits of the architect or stone-cutter who has erected them. The only question asked is, "How much did it cost?" and the only suggestion is that of vulgar wealth. "Yet all here," to quote from quaint old Sir Thomas Browne, "are but Babel vanities. Time sadly overcometh all things, while her sister Oblivion reclineth somniferous, making puzzles of Titanic erections, and turning old glories into dreams." The only lasting monument a man can build is the reputation he makes during life and the memory of the benefit which he has, in some form or other, conferred on those who live after him.

"For the good dead through the ages  
Linger in his-story pages  
Ever gleam and grow immortal,  
Unconsumed by moth and rust."

From all these considerations, I feel justified in expressing the belief that the ideal of the future of the Academy which I have given will at no remote period prove to be history. I hope to live to see it well begun, and I have the strong conviction that some now present will see it in full accomplishment. Some man of wealth, fully comprehending the im-

portance of this Academy, not merely to the profession, but still more to the public, will esteem it a privilege to have his name prefixed to our new hall by furnishing the requisite sum to build it and perfectly equip and support it; others will contribute the necessary amount to give their names to each of the special museums that I have mentioned, and others will place their names on an alcove in the library.

I here crave indulgence for one remark, the only one personal to myself: I trust this evening will end, on my part, all official connection with any medical societies. The remainder of my life, except the time necessary for bread-winning, will be devoted to putting on record the results of more than forty years of study, observation, and experience, with the hope that this may be of some value to the younger men of the profession, and to doing all in my power to urge forward that future of our Academy which I have anticipated.

I have but a few words to add before introducing my successor. Some years ago, when elected to a similar honor in another society, I remarked: "Scientific societies seem to be governed in their selection of office-bearers by one of two principles. One is to confer honor on those who by their contributions to literature and science have won a right to it. The other is to select such as will most efficiently perform the duties which pertain to the office."

In the election of my successor the Academy has most happily combined both of these principles. His literary and scientific work have won for him an enviable fame and high distinction, equally in this country and in Europe. His ability as a presiding and executive officer, has already been successfully tested by his former service as President of the New York County Medical Society and of the Medical Society of the State of New York. Thus he begins his career with a prestige which is a promise of great success.

I now have the pleasure of presenting to him the "loving-cup," on which his name has already been engraved, and which is to be transmitted to his successors in turn. It is ornamented with the symbol of friendship and love, and on it is the sentiment engraved "May peace and love be multiplied unto us."

Some years ago the phrase was very current in the political world, "Let us have peace." It is as wise a sentiment for the medical as the political world. I sincerely hope that my successor will never have to qualify this with the paradoxical appendix, "Let us have peace, even if we have to fight for it."

Of 1,724 students in medicine at Edinburgh during last year, 605, or more than 35 per cent., came from England, and 23 per cent. from the British colonies or from foreign countries. That is, over 1,000 men are studying at Edinburgh, who, under equal, or nearly equal, inducements in the way of medical advantages, would have naturally gone to London. That the attraction at Edinburgh was not an easy degree is shown by the fact that only 184 received the degree M.D., which, taking the average as 100, is less than 50 per cent.

## THE USE AND ABUSE OF BATTEY'S AND TAIT'S OPERATIONS.

BY WILLIAM H. BAKER, M.D.

WITH the great relief of suffering which has come since and through the inauguration of the operations for the removal of the ovaries and Fallopian tubes, there has been almost of necessity an unwarrantable advocacy of these surgical procedures in many cases where the above operations were in no way indicated. Nor is this surprising when we remember the enthusiasm and zeal which is requisite to establish any new departure in surgery, and especially when that device is ranked among the capital operations; for if the question of life and death is involved the profession are slow to adopt a new operation, even though in the hands of the deviser it give great promise.

This conservatism has its many advantages, as its tendency is to establish any given operation on a more sure foundation, so that its proper limits become well understood before over-zealous advocates, applying it to cases so unsuitable that the result must be only failure and disappointment, bring upon it first discredit, and then neglect and abandonment. The courage and conscientious work of Dr. Robert Battey in performing the first operations for the removal of the supposed normal ovaries to bring about the premature establishment of the menopause can never be forgotten, nor would we overlook the brilliant operations of Mr. Lawson Tait, in which by the added removal of the Fallopian tubes the scope of the operation was extended to a much larger class of sufferers, or the importance of his additional steps in securing results which were sought in the first-mentioned operation, but which the second seems to more perfectly attain.

The operation, then, of the removal of the uterine appendages for various conditions may be said to have safely passed its first danger, and to have become an established and well-recognized surgical procedure, but with this security in its general adoption arises another great risk common to nearly all operations at this stage, that of its frequent application to cases where no such serious method of treatment is necessary, and which can be perfectly cured by less severe means, without sacrificing parts which may prove to be of the greatest consequence to the patient's future happiness.

That many of the fears of patients submitting to this operation, such as change in form, manners, or voice, or loss of sexual desires, have proved ungrounded is quite true, but when we remember that by its successful performance we forever cut her off from child-bearing, I am sure the wiser and more cautious gynecologist will reserve this method of treatment for extreme cases, which fail to yield to the careful application of less severe but judiciously chosen modes of treatment.

In order to illustrate the special points of this paper I will report four cases, the first two of which indicate an unquestionable class for the proper performance of these operations, while if the

same surgical means had been carried out in the last two cases there certainly would have been gross abuse of the procedure.

**CASE I.** *Removal of the Ovaries for Cystic Disease.* Miss W. was brought to me March 28, 1883, by Dr. Thompson, of Fitchburg. She was thirty-eight years of age, and had complained of the trouble for which she sought advice for fourteen years. For the first few years of her illness she was generally weak and unable to walk, and from that time there had gradually come on backache and pain in both groins, a dull ache all over the abdomen, and occasionally sharp pain through the hips, which became so severe that for a year previous to seeing her she had been obliged to give up trying to walk. She had never been very strong, and the foregoing all attempts to walk out was a serious deprivation, as her general health suffered much in consequence. Riding caused more pain than walking. Menstruation began at twelve years of age, and had continued regularly afterward, occurring each twenty-six days, and lasting from three to five days. The amount of flow in her early life had been from ten to fourteen saturated napkins, but since her illness the amount had steadily diminished, until the whole flow would not soak four napkins. She had always suffered dysmenorrhea, but after she became more or less an invalid this symptom was much more prominent, the pain beginning from a few days to a week before the flow, and lasting throughout the period. She was usually confined to her bed four days. She had some leucorrhœal discharge, characterized as thin and whitish. She also reported frequent micturition and a feeling of pressure over the bladder. The condition of the bowels varied, being at times constipated and at other times too loose. She was obliged to lie down a great deal of the time. Physical examination made bimannually showed the left ovary to be enlarged to the size of a small hen's egg; the right ovary could not be distinctly felt. She was advised to have a leech applied to the cervix uteri a few days before each menstrual period, and an application of Churchill's iodine to the left cul-de-sac of the vagina once or twice a week in the inter-menstrual period. Her physician was to carry out the treatment, and to bring her to me again in six months.

October 12, 1883. She was admitted to the Free Hospital for Women, and on the twenty-third of that month she was examined under ether, and both ovaries were found to be enlarged, the left being the larger and more prominent. By the vagina, the size, compared with six months previously, did not seem to be much changed. There had possibly been a slight amelioration in her suffering from the treatment prescribed. She was advised to continue the treatment for six months more before deciding to have Battey's operation performed.

May 19, 1884. The patient was readmitted to the hospital, and reported no improvement, and, on examining her under ether, there was an apparent increase in the size of both ovaries over that which was found at the last examination. May 22d laparotomy was performed. Both ovaries were found to be enlarged to the size of a large peach, and were cystic. They were removed entire, and a

very small dermoid cyst on the left ovary, about the size of a large hickory nut, was ruptured in its removal. The operation was done under carbolic spray, and the strictest antiseptic precautions were observed. Greater care than usual was taken in sponging out the abdominal cavity, on account of the discharge of the contents of the dermoid cyst into it. Temperature touched  $102^{\circ}$  F. the evening of the second day, but gradually dropped to  $99.5^{\circ}$  F. on the morning of the fourth day, and kept between  $99^{\circ}$  and  $100^{\circ}$  F. for the next three weeks, during which time an abscess formed in the abdominal wall at the site of the incision, and, discharging, caused a separation of the wound at centre of the line of incision about an inch in length, which had nearly healed when she went home, June 28th.

In a letter from Dr. Thompson, dated January 5, 1885, he reports that the unhealed portion of the wound closed slowly, and that even then there was a small fistulous track extending some two and one-half inches downward, backward, and to the left, which occasionally discharged a thin, seropurulent fluid.<sup>1</sup> She had menstruated once since the operation, the last of November, 1884. This period lasted three days, although the whole amount of blood lost would not more than saturate one napkin. With the exception of increased nervousness and some pain in the back, the menstruation was comfortable.

I should judge from her physician's account that her condition, although very much improved over what it was before the operation, was in a state that required much to be done in the way of building up her general physical and nervous strength, and in the healing of the fistulous track referred to.

**CASE II. Removal of the Uterine Appendages for Fallopian Dropsy.** Mrs. M., a native of France, and resident of New Haven, Conn., was admitted to the Free Hospital for Women October 8, 1884. She was forty-three years of age, had been married nine years, but had had no children and no miscarriages. Her family history was not very good, her mother and aunt died of phthisis, and three sisters from nervous disease. Menstruation began at thirteen, and she was regular afterward, but she always had great pain, and was confined to her bed at such times.

When sixteen she had a severe hæmorrhage; on waking in the morning she found her bed soaked through. This was at a menstrual period, and at that time there was no dysmenorrhœa. When thirty-five she had another hæmorrhage at her menstrual period, and felt much relieved after it. For several years she had menstruated each twenty-five days, each period lasting four days, and its amount being large and accompanied by the passage of clots. There had been persistent leucorrhœal discharge for fifteen years. She thought she had peritonitis two years before her admission to the hospital. During nearly all her married life coitus had been painful, and for the day or two following this act she suffered from sinking feelings, "fainting spells." Her principal complaint before the menstrual periods was severe pain in the abdomen and legs, and weakness,

these difficulties being much aggravated when she was on her feet, or if even while sitting or lying she made much use of her arms; she was obliged to give up all such attempts, and to live a life of nearly complete invalidism.

A physical examination, made under ether, revealed the uterus enlarged by an interstitial fibroid in its posterior wall to about the size of the gravid uterus at two and one-half months, and apparently both ovaries increased to the size of duck's eggs. These were in close apposition to the uterus, and were movable with it.

October 29th. The patient being etherized, with the assistance of the hospital staff, I performed Tait's operation, every antiseptic precaution being taken. The abdominal incision was three and one-half inches long. The ovaries were found enlarged, but not at all to the extent that had been apparent in the physical examination. What had then appeared to be the enlarged ovaries were found to be the Fallopian tubes enormously distended with a clear fluid. In removing these the left and larger was ruptured. The ovaries themselves were underneath and behind the distended tubes, and had not been felt in the previous examination. In closing the abdominal wound Hunter's method was followed of first stitching together, with catgut over stitch, the edges of the peritonæum, and then closing the abdominal wound with interrupted silver sutures.

November 5, 1884. The stitches were removed and union was found to be good. The temperature once reached  $101.5^{\circ}$  F., on the third day, but for most of the time during two weeks it ranged between  $99^{\circ}$  and  $100^{\circ}$  F., and the pulse ordinarily at 90. After two weeks both temperature and pulse were normal. The most suffering which she had was from wind.

December 13, 1884. She was discharged cured.

In a letter from her dated January 15, 1885, she says that no menstruation has occurred since the operation, that the severe pain which she formerly felt in the abdomen and legs has entirely disappeared, and that she can walk with comfort. Her report was most satisfactory, and with the exception of some symptoms of nervous debility, such as "hot flushes," I should think her health fully restored.

In the foregoing cases it would have been foolish to delay the operation longer. The fact having been established that organic change of the ovaries or tubes had taken place, which incapacitated them from fulfilling their proper functions, or made them the cause of continued suffering, the sooner the remedy was applied the better for the patient, for she might then be saved years of exhausting pain. Nor was there anything to hope in the retention of organs so thoroughly disorganized, for the possibility of their being able to perform their functions had long since ceased. A longer delay did not seem advisable on the ground that a probable enlargement of the tumors would render the operation more easy, though in the first case such a change was to be expected; for with the readiness and greatly increased safety with which laparotomy can now be performed, such delay would only prolong the suffering of the patient without giving her any adequate return.

One of the good results growing out of the estab-

<sup>1</sup> In a more recent letter from Dr. Thompson he reports the fistula track closed.

lishment of this operation, aside from the benefit derived from it by the class of cases for which this procedure was especially designed, has been its effect on the treatment of ovarian cystoma in general, influencing, as it has, the much earlier removal of such tumors, and it seems only a reasonable prediction to make that the work of the ovariologist in the not distant future will be confined to the removal of tumors of small size; that the operator will be the most successful, other things being equal, who can early make his diagnosis sure.

By the citation of the foregoing cases I would not be understood to limit the field of these operations only to these classes, for I am well aware that it has quite as appropriate a place in any cases where the mental or physical state of the patient is seriously jeopardized by the process of menstruation, and where the only hope for mental or physical health lies in its cessation.

It is rather my design that the instances given should represent the class in which structural changes leave no doubt as to the advocacy of the removal of the uterine appendages, and also those others that serve as a text to caution the profession at large against the too hasty acceptance of this extreme measure in cases where it *may* be that *there exists* some abnormal change either in the size or the position of the ovaries which with appropriate treatment might be readily relieved, and that in these laparotomy should only be advised after such well-directed care has failed to cure.

CASE III. *Ovarian Dysmenorrhea dependent upon the Opium Habit.* Miss K., a school-teacher, twenty-eight years of age, a native of an adjoining State, entered the Free Hospital for Women March 8, 1881, for the purpose of having Battey's operation performed. She had always been well until eight years before, when she had pneumonia followed by phlebitis, and had suffered more or less ever since. Menstruation began at fourteen, and continued regularly afterward, lasted four days, and in amount was equal to five saturated napkins. It was unaccompanied by pain until after her attack of pneumonia, but since that time she has suffered great dysmenorrhea, the pain beginning several days before the flow, and continuing not only throughout it but for several days afterward. She also complained of pain in both ovarian regions, particularly the left, and so much sensitiveness there that any pressure could not be tolerated. There was some leucorrhœal discharge, characterized as thick and yellowish. Her nervous strength was in a deplorable condition, and she had long before been obliged to give up her duties as a teacher. After her attack of pneumonia, from which she dated most of her troubles, her physician had given her morphia for her suffering; had even gone so far as to teach her to use it subcutaneously, and had provided her with a syringe and an abundance of the nux-om-sei alkaloid. On account of the amount of pain complained of she had felt obliged to continue its use until she was alarmed at the amount consumed and at her dependence upon it. She therefore determined, two years before my seeing her, to enter a hospital at Concord, N. H., for the purpose of discontinuing the morphia. She succeeded in reducing the amount from twelve grains a

day to half a grain. She was then told by the physician in charge that she could never hope to give up entirely the drug while she suffered so much at her menstrual periods. She next sought relief in a hospital in New York, where in discontinuing the drug she became very ill, and the amount was greatly increased. She was then examined by a well-known gynecologist, who diagnosed displacement of the left ovary, and advised Battey's operation as the only means which would enable her to give up the morphia. On account of her great weakness the performance of the operation was postponed. When she entered the Free Hospital she was taking six grains of morphia daily subcutaneously. A physical examination made under ether showed the uterus and ovaries to be in a position of slight retrocession; but as there was no evidence of inflammatory action, either present or past, about the pelvis, this position of the organs was considered rather one of congenital origin. There was a slight endocervicitis present. Inasmuch as there was no structural change found in the ovaries or tubes, she was advised to discontinue the morphia at all hazards. After the two unsuccessful attempts that she had already made, with the great suffering which necessarily accompanied such efforts, she was rather reluctant to undertake another trial in the same direction, and much preferred to submit to the results of Battey's operation, which had already been described to her. She, however, soon gave her consent to the plan proposed.

With no inconsiderable experience in breaking up the opium habit, I can truly say that I never saw a patient suffer more than this woman did in the four weeks after the cessation of the morphia. Neither have I ever, with a single exception, seen one so alarmingly reduced. In three months she was sent into the country with a reliable nurse, who remained with her for three months more. In six months the local symptoms had begun to grow less, and in a year they had entirely disappeared. She was able to engage in active employment in six months, and within a year was fulfilling the duties of a position which required an extreme amount of mental and bodily strain. She has continued this employment up to the present time, and I have been assured within a few days of her continued health and strength. When last examined the uterus and ovaries were still in the position already described, but they had long before ceased to occasion any suffering.

CASE IV. *Left Retro-Lateral Version of the Uterus, with Prolapse and Enlargement of the Left Ovary.* Miss E., twenty-six years of age, first consulted me in 1880. She had never been very strong, and her heredity was far from the best. She had suffered almost since her first menstruation from a dragging feeling in the pelvis and from dysmenorrhea. The latter gradually disappeared, but returned in 1876. The former symptom remained. All through her early life she thought she must walk, and therefore persisted in doing so, though she felt much the worse for it afterward. In 1874 she first called a physician, and was treated for two years, for what she does not know. In 1876 she went to one of the most eminent gynecologists in this country, and remained under his care much of the time for

two years. In 1878 she left him, being told that "nothing could be done for her." She found that the more treatment she had the worse her general condition became. She had an attack of cellulitis in 1877, from which she was four or five months in recovering. She gained somewhat in general health after leaving off treatment, but the local discomfort remained much the same. Menstruation appeared at eleven, and continued regularly until about 1874, when it began to come on four or five days too early, and has continued to do so since, except twice, when she refrained from riding and walking, and was so enabled to go the full time. Through early life menstruation lasted a week; but for four years previous to consulting me it was usually four days, which she spent in bed, though she did not go downstairs for six days. This patient was in an utterly hopeless state regarding herself, and I wrote to her previous physician, who then strongly advised Battey's operation. On carefully going over the case, however, it seemed to me that possibly the nervous strength, which had never been great, had been too severely taxed by previous treatment, and that the malposition of the uterus and ovary was probably due to a relaxation of the uterine and ovarian ligaments, due, in its turn, to this very lack of nervous tone. My treatment was directed to saving her all possible nervous fatigue, and to building up her general health by carefully regulating her diet, exercise, and, as far as possible, the expenditure of nervous force. The only local treatment given was the application of a leech to the cervix uteri just before each menstrual period, to insure thorough relief to the congestion of the enlarged ovary. This course was followed out for a year, at the end of which time the uterus had completely gained its normal position, as had also the ovary, which was then of natural size. The patient had become hopeful of recovery, and could bear greatly increased nervous strain without fatigue. In 1882 she had a severe trial in the death of one of her family, and she lost something of the ground gained.

The suffering was then confined largely to the menstrual period, which process exhausted her, not from actual pain, but from the faintness and weakness which it induced. With a view of securing a more thorough examination of the ovaries and tubes, I gave her ether, and found those organs, as well as the uterus, in every way normal.

In 1883 and 1884 I saw the patient at infrequent intervals, and the local condition continuing good. I was more and more convinced of the truth of my first supposition, that is, that the malposition of the uterus and ovary was primarily due to the relaxation of ligaments dependent on a want of nervous tone, and that active local treatment only increased the difficulty by so much the more as it taxed the nervous strength. It has also been sufficiently shown that in just so far as her nervous strength improved in the same ratio the weakness and exhaustion at the menstrual periods lessened, and that her whole difficulty was one of nervous origin.

In cases III. and IV. the operation for the removal of the ovaries and tubes would have been as unjustifiable as it was warrantable in cases I. and II. The third case shows that although the patient

suffered from great dysmenorrhœa, and from ovarian pain and tenderness in the inter-menstrual period, yet the degree or importance of this pain could not be determined so long as she was using morphia; and the ovaries and tubes giving no evidence of disease in themselves they would, if removed, have been needlessly sacrificed, and the patient would not only have been subjected to the dangers of the operation, but she would have had the same struggle to go through with afterward in the discontinuance of the opium, and this, if successfully done, would have given unjust credit to the operation.

The fourth case well illustrates how easily the best of us may be mistaken in judging of cause and effect in uterine and ovarian disease. Almost any one finding a retroverted uterus and a prolapsed and enlarged ovary would see therein cause sufficient not only to occasion great disturbance, but to perpetuate it, and would feel unwilling to go on without rectifying the malposition, particularly if we had every reason to believe that from the absence of adhesions this could be readily accomplished. Had this not been most faithfully tried by one in whom I had the most implicit professional confidence, I should probably have fallen into the same error; but realizing that as a cause of the nervous debility the local treatment had been faithfully tried and failed, and seeing in her whole history and in that of her family sufficient reason to consider the uterine and ovarian symptoms an effect rather than a cause, I was led to treat it as such with sufficiently good result to make that plain, and to show that the permanent cure could only come through the establishment of the nervous strength; that the sacrifice of the ovaries would not only be useless, but would greatly increase the difficulty through the large nervous tax that the operation and the subsequent convalescence must demand. In conclusion I would suggest the following:—

(1) That these operations be restricted to cases in which structural changes in the ovaries or tubes have been clearly made out in advance, and where well-directed treatment of less formidable character, though perseveringly tried for several months, has wholly failed to give relief.

(2) That, in addition to the foregoing, the removal of the uterine appendages may be necessary in some cases where the process of menstruation immediately jeopardizes the life or the mind of the patient, even though no structural change in these organs can be previously diagnosticated.

(3) That when once the diagnosis of cyst of the ovary has been established, delay in its removal only increases the danger to the patient without giving any adequate return from the increased facility in performing the operation gained by the greater size of the cyst.

(4) An exploratory incision may sometimes be warrantable if, from various reasons, there is an inability to perfect the diagnosis without.

# RECENT PROGRESS IN FORENSIC MEDICINE.

BY F. W. DRAFER, M.D.

## CAUSES OF ERROR IN THE INVESTIGATION OF CASES OF RAPE.

IN a paper read before the Medico-Legal Society of Paris, Professor Brouardel discusses quite fully the difficult points in the diagnosis of rape, especially as they apply to little girls.<sup>1</sup> The two prime sources of error, he says, to which the physician is subject are, first, the anxious behavior of the mother, who is convinced that her child has been assaulted, and second, the falsehoods of the child herself who has fabricated the story, the main points of which have been suggested to her. In such cases a medical man ought to use his eyes and not his ears, and he ought to be very careful to state only what he has himself seen. The state of the hymen will naturally engage his most serious attention. In well-nourished children the hymen is deeply placed, owing to the deposit of fat in the labia majora; in such cases much perseverance and gentleness are required to gain a view of the hymen at all; and it is in just such instances that medical men make the mistake not infrequently of declaring that the membrane has disappeared. On the other hand, in thin, ill-nourished children, the labia majora hardly exist, and the hymen is found easily at a depth of scarcely more than a centimeter from the surface. In form it varies considerably: it may be of the typical labial shape, with two or more folds in the segments, so that the orifice is quite dilatable. These folds or reduplications should not be mistaken for old rents. Again, the hymen may be crescentic, with the orifice situated anteriorly and the free border of the membrane presenting notches which are to be distinguished from the results of violence. In still a third form, the hymen appears as a membrane across the ostium vaginæ with two symmetrical orifices, one on each side of a median bridge stretched from the anterior to the posterior wall of the vagina. Frequently the middle of this bridge has disappeared, and one or two projections or "*languettes*" remain in its place.

In inspecting the hymen in children it is to be remembered that if the thighs are widely parted the membrane is put on the stretch. It is sometimes necessary to make the child cough or force down, in order to obtain a satisfactory view of the parts. To make sure that the hymen is intact, the finger or a blunt hook should be passed behind it to smooth out the edges; it is only in this way that the difference between the natural folds and cicatrices can be demonstrated.

Vulvitis may be spontaneous, traumatic, or gonorrhœal, and there are no absolutely certain means of diagnosing one from the other. Erythrit, especially if of long duration, is a valuable indication of contagion, but is not conclusive proof. Gonorrhœal erythrit, as a rule, is more persistent than traumatic erythrit. Spontaneous or idiopathic vulvitis is very common in children of lymphatic temperament, particularly during teething and at puberty. It may be acute or chronic,

and it is contagious. Swelling of the inguinal glands is more common in the gonorrhœal variety of the disease, but it is not confined to that variety. When consulted in medico-legal cases of vulvitis, medical men are generally too hasty in giving a decided opinion, from fear of being thought ignorant or inexperienced; a decided conclusion should never be based on a single inspection. In most cases repeated visits are necessary in order that the course of the inflammation may be observed; for example, severe bruising of the parts may not appear for several days after the violence which caused it, and the first examination may have been premature.

Ulcerations of the vulva are described by Brouardel as of the following varieties: (1) indurated primary sores; (2) soft sores; (3) mucous patches; (4) herpetic ulcers; (5) superficial ulcerations from intense, spontaneous, traumatic, or gonorrhœal vulvitis. The author cautions against the mistakes of hasty diagnosis in studying these lesions.

## RUPTURE OF THE BLADDER.

The following is a summary of a portion of an article on lacerations of the abdominal viscera, by Dr. B. Beck, surgeon-general of the German army, and is useful medico-legally on account of its clear statement of the lesions which external violence of various kinds and under various conditions produces upon the urinary bladder.<sup>2</sup> Rupture of this organ, says Beck, may result from a fall on the abdomen, from a blow by some heavy body coming down upon the abdomen, from a fall in which the feet or lower part of the body first strike the ground, by the body of the patient coming suddenly against a resisting object, or from the steady pressure of some heavy mass on the front of the abdomen. The position of the body at the moment of injury contributes to determine the seat, form, and extent of the rupture. The bladder is always torn at one of its two weaker points—its anterior and its posterior wall—according to the direction of the external violence acting on the contained urine. Knowing this direction, the surgeon may diagnose with fair accuracy the seat of the rupture. If the violence is brought to bear upon the front of the abdomen, forcing the fluid contents of the bladder downward and backward, the rent will be found in the posterior wall and within the peritonæum. On the other hand, if the patient falls from a height and strikes on the feet or buttocks, with the body bent forward, the urine will be forced forward by the pressure of the abdominal viscera from above and behind, and a rent will result in the lower part of the anterior wall of the bladder and outside the peritonæum. (Conversely, the position of the rupture, as found postmortem, will enable the examiner to state the direction in which the violence was brought to bear upon the bladder, and, approximately, the character of the force applied.)

Dr. Beck states that his experience has convinced him that death in cases of ruptured bladder is due, not to peritonitis, but solely to poisoning of the blood and consequent paralysis of the heart,

<sup>1</sup> *Annales d'Hygiène publique et de Médecine Légale*, x. Nos. 7 and 8.

<sup>2</sup> *Deutsche Zeitschr. f. Chirurgie*, xiv., 485. *London Med. Record*, June 10, 1884, 236.

through absorption of decomposed urine. This poisoning takes place most rapidly when the lesion is intra-peritoneal.

#### NON-EXPERT TESTIMONY IN INSANITY CASES.

In his work on "The law of expert and opinion evidence,"<sup>3</sup> Mr. Lawson says that "as a general rule persons who are not medical men cannot give their opinions as to the existence, nature, or extent of disease in any one. Quite early, however, an exception to this rule was recognized which permitted the subscribing witnesses to a will to be called upon for their opinion as to the sanity or insanity of the testator. This species of evidence was extended so as to include other cases in which the sanity of the party interested was in dispute. It was introduced without much argument in the English courts, and has been received without debate in the courts of all the States, except those of Massachusetts, Maine, New Hampshire, and Texas."

Within a short time the Supreme Court of the United States has had occasion to render its judgment on the question whether the testimony of witnesses who were not medical men was admissible in a matter of opinion concerning sanity, and the decision of this court is of such obvious importance that it is worth quoting at large. The case at issue was one in which the Connecticut Mutual Life Insurance Company was defending a suit on the ground that the policy-holder had killed himself when sane—a condition whereby the company was released from liability. The court gave the following opinion:—

"Counsel for the plaintiff in error contends that witnesses who are not experts in medical science may not, under any circumstances, express their judgment as to the sane or insane state of a person's mind. This position, it must be conceded, finds support in some adjudicated cases, as well as in some elementary treatises on evidence. But, in our opinion, it cannot be sustained consistently with the weight of authority, nor without closing an important avenue of truth in many, if not in all, cases, civil and criminal, which involve the question of insanity. Whether an individual is insane is not always best solved by abstruse metaphysical speculations expressed in the technical language of medical science. The commonsense and, we may add, the natural instincts of mankind reject the supposition that only experts can approximate certainty upon such a subject.

"There are matters of which all men have more or less knowledge, according to their mental capacity and habits of observation—matters about which they may, and do, form opinions sufficiently satisfactory to constitute the basis of action. While the mere opinion of a non-professional witness, predicated upon facts detailed by others, is incompetent as evidence upon an issue of insanity, his judgment, based upon personal knowledge of the circumstances involved in such an inquiry, certainly is of value; because the natural and ordinary operations of the human intellect, and the appearance and conduct of insane persons, as contrasted

with the appearance and conduct of persons of sound mind, are more or less understood and recognized by every one of ordinary intelligence who comes in contact with his species. The extent to which such opinions should influence or control the judgment of the court or jury must depend upon the intelligence of the witness, as manifested by his examination, and upon his opportunities to ascertain all the circumstances that should properly affect any conclusion reached. It will also depend in part upon the degree of the mental unsoundness of the person whose condition is the subject of inquiry, for his derangement may be so total and palpable that but slight observation is necessary to enable persons of ordinary understanding to form a reasonably accurate judgment as to his sanity or insanity; in other cases the symptoms may be of such an occult character as to require the closest scrutiny and the highest skill to detect the existence of insanity."<sup>4</sup>

(To be concluded.)

## Reports of Societies.

### MEDICAL SOCIETY OF THE STATE OF NEW YORK.

SEVENTY-NINTH annual meeting, held in Geological Hall, Albany, February 3, 1, and 5, 1885.

#### FIRST DAY.—MORNING SESSION.

The President, DR. B. F. SHERMAN, of Ogdensburg, was in the chair. Dr. Henry I. Bowditch, of Boston, was present, and on motion of Dr. S. B. Ward, of Albany, was received as an honorary member, taking his seat by the side of the President amid much applause.

#### THE PRESIDENT'S OPENING ADDRESS.

was read by DR. SHERMAN, and the following are a few extracts from it: "We live in an age of wonderful improvements, and our profession in all its branches has kept fully abreast with the age. One of its latest gifts to suffering humanity is the new anæsthetic, cocaine, which promises, in its relief of pain and suffering, to be second only to ether and chloroform, and to simplify many important, as well as minor, surgical operations. . . . To make this (one of the oldest and largest State medical societies) what it should be, demands an earnest effort on the part of us all, and perhaps some change in programme. We should have a better room in which to hold our meetings—one with better acoustic properties, as well as better ventilation. . . . Too many members and delegates come here to serve two masters—to represent their county societies in this meeting and at the same time to represent their local Masonic lodge in the Masonic convention, or to see and study the white elephants of the city. We should have a less number of papers and devote more time to the discussion of the few. . . . We should once more memorialize Congress to furnish a fireproof building for the preservation of the National Medical Library and Museum. . . . I would respectfully advise the

<sup>3</sup> The Law of Expert and Opinion Evidence, reduced to Rules—By John D. Lawson. 1883.

<sup>4</sup> N. Y. Med. Jour., November 29, 1881, p. 621.

amendment of Article XI., Section 2. of the By-laws in a way to require but one address, instead of two as at present, from the President, and that to be made at the opening of the first day's session." In the course of the address Dr. Sherman spoke with much feeling of the deaths of Drs. S. D. Gross and Willard Parker.

#### COMMITTEES APPOINTED.

The President announced a number of committees, Dr. J. V. Kendall being chairman of the committee on business, Dr. Eugene Brach chairman of that on credentials, and Dr. W. W. Potter of that on inaugural addresses.

#### PAPERS READ.

The following papers were read and discussed: "Pelvic abscess," by Dr. W. W. Potter, of Buffalo; "Jequirity as a remedy for granulated lid," by Dr. David Webster, of New York; "Legislation," by Dr. Daniel Lewis, of New York; "On the removal of the crystalline lens with its capsule," by Dr. D. B. St. John Roosa, of New York. The following papers were read by title: "The uses and limitations of hydrochlorate of cocaine," by Dr. C. R. Agnew, of New York, and memorial addresses on Dr. John Richard Cotes, by Dr. W. Warren Pitten, of Buffalo; Dr. Joel Foster, by Dr. F. V. White, of New York; Dr. John G. Adams, by Dr. G. M. Smith, of New York, and Dr. James R. Wood, by Dr. Frederick R. Dennis, of New York.

#### STATE BOARD OF MEDICAL EXAMINERS.

Dr. H. G. Piffard, of New York, read the report of the special committee on "The medical examiners bill," and presented a draft of a bill constituting a State board of medical examiners. This bill provides for the formation of two boards of examiners, to hold office for one year, and to be known as the Northern and Southern Boards of Examiners. After some discussion, the bill was made the special order of business at the evening session.

#### AFTERNOON SESSION.

The nominating committee was appointed, by the President, with Dr. S. Oakley Vanderpoel, of New York, as chairman. The following papers were then read: "Anatomical geometry and toponomy," by Dr. N. Josiah Roberts, of New York; "Some observations on hydrochlorate of cocaine," by Dr. T. R. Pooley, of New York; "Peroxide of hydrogen," by Dr. T. S. Wallian, of Rhydale; "Abstract report of cancer of the liver, characterized by series of low temperatures," by Dr. W. S. Ely, of Rochester; "Tubal pregnancy," by Dr. T. H. Squires, of Elmira; "Does quinine abort pneumonia?" by Dr. L. Emmet Holt, of New York.

#### EVENING SESSION. MEDICAL EXAMINERS.

The President announced as the special order the consideration of an act "To establish a northern and southern board of examiners of the State of New York, to regulate the licensing of practitioners of physic and surgery." A heated debate, which

was continued until eleven o'clock, followed, and was participated in by Drs. Hopkins, Roosa, Piffard, Ely, Seymour, Vanderpoel, Vandever, Ward, Bendell, Jacobi, Johnson, Lewis, Knapp, Curtis, Kendall, Priddy, Loomis, Sturgis, Potter, and Squires. Finally, Dr. Jacobi proposed as a substitute for this measure Assembly bill No. 45, which was introduced January 27th, and, on motion of Dr. Vanderpoel, the latter was ordered to be printed and made a special order for the afternoon session of the following day.

#### SECOND DAY. — MORNING SESSION. TREASURER'S REPORT.

The treasurer, Dr. C. H. Porter, of Albany, read his annual report, which showed that the receipts during the year amounted to \$3,743; disbursements, \$3,363; balance, \$380. It was also stated that \$685 of the Merritt H. Cash prize for meritorious essays was on deposit in the Albany Savings Bank. After reports from a number of committees had been made, the following

#### PAPERS

were read: "Senile hypertrophy of the prostate," by Dr. Alfred C. Post, of New York; "An electric light for ophthalmic and aural surgery," by Dr. L. Howe, of Buffalo; "The opium habit," by Dr. F. M. Hamlin, of Auburn; "Culture experiments with bacteria," by Dr. Wm. Hilles, Jr., of Albany; "Hare-lip," by Dr. W. N. Phelps, of Chateaugay. On motion, the consideration of "The medical examiners bill" was ordered for the hour of 4.30 p.m.

#### AFTERNOON SESSION.

Papers were read as follows: "Some practical points in the treatment of granular lids," by Dr. W. F. Mittendorf, of New York; "Urethral stricture, with exhibition of improved instruments for stone," by Dr. F. N. Otis, of New York; "Maternal nursing," by Dr. J. E. Winters, of New York; "A new method of electric illumination of the throat," by Dr. W. C. Jarvis, of New York; "Some observations on the operation of abdominal section as performed by Mr. Lawson Tait, with a report of five cases in my own practice," by Dr. Albert Vandever, of Albany.

#### PAPERS READ BY TITLE.

The following were read by title: "Trichina and trichiniasis," by Dr. H. Jewett, of Canandaigua; "The elements of perturbation in uterine therapeutics," by Dr. F. H. Foster, of New York; "The treatment of pelvic abscess," by Dr. P. F. Mundé, of New York; "Abscess of the liver," by Dr. W. E. Bullard, of New York; "Memorial of the late Dr. Jacob S. Mosher," by Dr. Willis G. Tucker, of Albany.

#### MEDICAL EXAMINERS.

Dr. Jacobi withdrew his motion to adopt Assembly bill No. 45, and Dr. Piffard, from the special committee, then made a report recommending that the bill previously reported be referred to the standing committee on legislation with instruction to modify it by certain specified amendments which had been discussed the previous evening, and

push its passage by the Legislature; which report was unanimously adopted. The bill, as amended, provides for a single board of examiners, composed of nine members, who are to be elected for one year (but subject to reelection) by the Regents of the University of the State of New York. Six of the board are to be members of the regular State Medical Society, two of the Homeopathic State Society, and one of the Eclectic State Society; and of the six first named three are to be representatives of the incorporated medical colleges of the State.

## EVENING SESSION.

## THE ANNUAL ADDRESS BY THE PRESIDENT

was delivered in the assembly chamber at the Capitol, and was on the subject of "Medical evidence." On adjourning the Society proceeded to the Delavan House, where the

## ANNUAL BANQUET

was held. There were upward of two hundred members and invited guests, and Dr. S. B. Ward, of Albany, acted as toastmaster. Among the toasts responded to were the following: "The Medical Society of the State of New York," Dr. B. F. Sherman; "The State of New York," Hon. St. Clair McKelway; "The Law-makers," Hon. George Z. Erwin, speaker of the assembly; "Medical codes," Dr. Henry I. Bowditch, of Boston; and "The ex-Presidents of the State Society," by Dr. S. Oakley Vanderpoel.

## THIRD DAY. — MORNING SESSION.

## CHOLERA.

AN address on the prevention of cholera was given by DR. S. OAKLEY VANDERPOEL, the former health officer of the port of New York. The following is a brief synopsis of his remarks: There is cholera existing in the city of Bombay in a greater or less degree during the entire year. Through the intervention of steamers we are communicating with that city. Vessels leaving that port are thoroughly inspected at an island at the mouth of the Red Sea. England does not coöperate with other nations in establishing the proper quarantine of vessels hailing from cholera-infected ports. England offers the only obstructing factor. The disease usually breaks out among steerage passengers. Cholera can only reach this country by means of Europe. A thorough medical investigation should be made of every person going aboard vessels, and clothing examined, to see that no soiled linen is among the baggage of any passenger. Moreover, if the physician aboard the vessel bound for America makes a thorough investigation every day, and, in case the cholera should appear if the clothing is properly disposed of and the case of cholera given the proper isolated care, the individual case will, without doubt, be stamped out. But if a case of cholera arises on a steamer, the passengers should be disembarked on one of the quarantine stations and the case given proper care. Ten days after the disappearance of the last case of cholera the passengers may be embarked and allowed to proceed to their destination. In conclusion Dr. Vanderpoel remarked that he sincerely believed that, if the proper quarantine measures are taken, there would

be no cholera in this country during the coming summer.

The following resolution was then adopted, and a copy of it ordered to be sent to President Arthur:

*Resolved*, That it is the sense of the New York State Medical Society that the United States Government should, in view of the probable importation of cholera poison during the present year, promptly take steps to enforce proper sanitary measures where the disease exists.

## OFFICERS ELECTED.

The nominating committee reported the following officers, who were duly elected: President, Albert Vandever, Albany; Vice-President, Alfred C. Post, New York; Secretary, William Manlius Smith, Syracuse; Treasurer, C. H. Porter, Albany. Censors for the various districts were also elected. The following are the chairmen of the

## STANDING COMMITTEES CHOSEN.

*Arrangements and Business*, S. B. Ward, Albany.  
*By-Laws*, W. C. Wey, Elmira.  
*Hygienic*, E. V. Stoddard, Rochester.  
*Legislature*, Daniel Lewis, New York.  
*Ethics*, A. Jacobi, New York.  
*Prize Essay*, W. W. Potter, Buffalo.  
*Publications*, William Manlius Smith, Syracuse.  
A number of permanent members and the following

## HONORARY MEMBERS

were also elected: Dr. J. L. Cahill, of Virginia; J. F. Whittaker, of Ohio; F. G. Wormley, of Philadelphia, and F. S. Clouston, of Edinburgh, Scotland.

## THE DELEGATES TO THE MASSACHUSETTS MEDICAL SOCIETY

are Drs. M. L. Bates, B. F. Sherman, Frank P. Foster, Peter Faling, and John Gerin.

Dr. Frank S. Low, of Pulaski, read a paper describing "An instrument for irrigating the abdominal cavity in cases of ovariotomy," and a few farewell remarks were made by Dr. Bowditch, of Boston, and the President. Adjourned.

## BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M.D., SECRETARY.

JANUARY 26, 1885. The President, Dr. F. W. Draper, in the chair.

## MARKED TRICUSPID STENOSIS WITHOUT SYMPTOMS.

DR. W. W. GANNETT exhibited a heart showing a marked degree of stenosis of the tricuspid orifice, it admitting only one finger to the second joint.

The valve cusps were thickened and adherent along their edges of closure. The aortic and mitral valves showed evidences of earlier endocarditis, resulting in stenosis and insufficiency of both these orifices. All four cavities were enlarged and the walls thickened.

The individual was eighteen years old, had always been an industrious worker, and so far as

known had never presented any symptoms of cardiac disease.

Death had occurred from erysipelas of the head and face following upon a wound of the scalp.

#### UNILOCULAR OVARIAN CYST.

DR. JOHN HOMANS presented a specimen of unilocular ovarian cyst. The patient was thirty-two years old, married, and the mother of several children. The tumor which weighed twelve pounds had been recognized for a year. There were no adhesions, but a former tapping had left a portion of thickened wall as its mark. The pedicle was oedematous, and there was some ascitic fluid. (Edema of the pedicle is caused either by twisting, or by strangulation from other causes. In this case there was no twist, and edema was due to pressure.

While it is well known that cysts of the broad ligament are generally unilocular, yet an ovarian cyst, which this is, is commonly multilocular.

DR. A. T. CABOT said that rare cases commonly come in couples. He had removed a kidney-shaped unilocular ovarian cyst within two weeks. The contents resembled pea-soup, and held ovarian corpuscles.

There had been no rise of temperature and the patient was sitting up on the day of the meeting.

DR. W. H. BAKER read a paper on

#### THE USE AND ABUSE OF BATTEY'S AND TAIT'S OPERATIONS.<sup>1</sup>

DR. BOARDMAN said: Several years ago Professor Thomas made the observation that, in the immediate future, the greatest advances in gynecology would be made in the direction of ovarian, rather than of uterine, pathology. Events have shown his wisdom, and, as an outcome of this, we are indebted this evening to the reader for the very valuable paper, founded upon his personal experience and illustrating his recognized acuteness in diagnosis and wisdom in treatment. He was quite ready to assent to the general conclusions deduced by the reader as to the conditions which must be established in order to justify the operation for the removal of the ovaries. He believed it should first be determined that one or both of them is in a condition of disease. "Normal ovariectomy," or the removal of the ovary not affected with organic disease, not impaired in its functional activity, he was not prepared to accept as a legitimate operation; except as a means, in certain cases, to arrest the growth of fibroid tumors, or where the uterus is absent, or there is atresia in the utero-vaginal tract which cannot be relieved by the more common surgical procedures. He would not assent to the operation even in cases of deformed pelves where Cæsarean section and the like would be demanded should pregnancy ensue and continue uninterrupted, for in such instances he should consider that it belongs to the individual to protect herself from the danger to which she would be legitimately exposed. The last two cases cited by the reader illustrated exceedingly well the caution required of us in these days when there is tendency to resort too precipitately to comparatively new operations by no means demonstrated to be legitimate.

Perhaps most of us can recall similar cases: that is, patients who have been confirmed invalids for years, probably with the hysterical element largely predominant, who have been under the care of many physicians, have been declared incurable, and yet have finally been restored to health. He referred to such a case, in his own practice, who had been an invalid for fifteen or more years and had consulted many physicians. A distinguished gynecologist in New York had suggested removing the ovaries as affording a probable source of relief, although she had already passed the climacteric a few years. The speaker found upon examination no local disease, but an atrophied uterus, and the ovaries evidently were functionally dead and giving no evidence of any diseased condition whatever. Under judicious treatment she recovered within a year and has continued well since, except for occasional and rare paroxysms of mild hysteria. The speaker had carefully studied Battey's cases, more especially his first series of ten cases. To be sure, the reports give meagre details, but he was not convinced by them that the results warrant Battey's deduction that his operation is a legitimate one.

Future experience may, however, serve to confirm the theory, which, we must allow, is not unreasonable.

DR. BOARDMAN added that we should not forget cases which, probably, most of us have met with or heard about, where protracted invalidism has been arrested by something in the nature of a shock. A surgical operation, with all its attending preparations and paraphernalia, not infrequently imparts a severe shock, and it is easy to conceive that the fact applies especially to the nervous patients under consideration. Reasoning from this, he believed it not unreasonable to assume that, in some of these cases at least, the shock of the operation, intensified perhaps by the fact that it is regarded as a serious mutilation, may be the sole cause of the successful results which have been observed.

DR. J. P. REYNOLDS said that he was glad that the points in the paper had been emphasized.

DR. JOHN HOMANS said that we should rather speak of the ovary and its appendages: the tubes, the uterus, and the vagina: than of the uterus and its appendages. He thought that the influence of shock in helping these cases had been exaggerated. Many of the cures are not authentic, and many of the others are not permanent. A bed-ridden case of his own had fulfilled his own prophecy, given a few years earlier, by running out of the house when it was destroyed by fire, but she soon had a relapse. Are Dr. Baker's cases properly said to be Battey's or Tait's operations? Although Dr. Baker is undoubtedly informed; he, Dr. Homans, would have called them ovariectomies, being done for the relief of physical disease. He had himself done Tait's operation four times. The first case was restored to health, the uterus having been undeveloped; the second was unsuccessful, in that there was no improvement; the third case, recommended for operation by Dr. Cowles, survived the operation ten hours. The autopsy did not show any cause for the symptoms. The fourth case he reported more at length. It was done to prevent menstruation,

but also to cause the disappearance of a fibroid. The patient is forty-four. For two years her menstruation has been more and more painful, making her violent, and being only partly helped by enormous doses of morphia. While in this condition she has attempted the life of her husband. She came to Dr. Homans asking to be saved the need of going through another menstruation. Dr. Cowles, of Somerville, advised operating, provided her relatives confirmed her statements, which they did; and eight days ago the speaker had done Tait's operation. Her entire character seems to have changed.

DR. BOARDMAN said that he would consider this first operation as an ovariectomy for the removal of diseased ovaries. As he understood the matter, Dr. Battey named his operation "normal ovariectomy," or the removal of functionally active ovaries, while Mr. Tait removed diseased ovaries and with them the tubes — the essence of "Tait's operation" being the excision of the tubes — upon the theory that menstruation occurs within them.

DR. J. W. ELLIOT thought that the names applied to these operations were confusing and incorrect. The ovaries had been removed for prolapsus and in hernial sacs many times before the days of Battey. The first removal of the ovaries to cure disease by stopping menstruation was done by Hegar on July 27, 1872. About a month later, August 17th, Battey did his first operation, not knowing that Hegar had already done it. In the cases that soon followed Hegar found tubo-ovarian cysts and salpingitis and accordingly removed the tubes with the ovaries before Tait did. Neither Battey nor Tait has any claim to the name of the operation so far as priority goes. The operation as it is now done for every conceivable disease of the ovaries and tubes can hardly be called Battey's or Tait's operation.

The indications for the removal of the uterine appendages must, as yet, be considered unsettled, but they will, to a certain extent, depend upon the mortality. For if the operation is done where life is immediately or remotely threatened, as in cases of uterine hæmorrhage from fibroids, pyo-salpinx, malformations of uterus and vagina, small ovarian tumors, etc., a much higher mortality can be allowed than in cases of mere *invalidism*. Tait has justified the operation in this last class of cases by his very low mortality. Those who follow Tait then in these cases must show a low mortality. We are still very ignorant about the pathology and symptoms of these diseases. Even now that we know that salpingitis is a very common cause of chronic pelvic peritonitis, it is not certain that every case should be treated by this operation. Some of the cases so treated have continued to have the same inflammation and pain as before the operation. Some patients with salpingitis have no symptoms, while others are invalids. Some cases of salpingitis will probably get well without treatment, as do cases of metritis and urethritis. The operation has often been done for hydro-salpinx. This disease is simply a retention cyst and we do not know what symptoms it causes. Simpson reports eight cases as cured by tapping.

Not infrequently the ovaries removed by this operation have been found to contain follicular cysts.

No one knows if these cysts cause any symptoms whatever. When we turn to the symptoms we are no better off. How many women complain of "pain in the ovaries" when they are perfectly normal! And yet no one will doubt that most distressing local and reflex symptoms are sometimes caused by these diseases. In this unsatisfactory state of our knowledge on this subject we must do the best we can until the indications can be more clearly defined.

Hegar read a paper at the International Medical Congress, in Copenhagen, last August, on "Castration as a cure for nervous and physical diseases." It was clearly the sense of the meeting that the normal ovaries should under no circumstances be removed in such cases. That the symptoms were worse at menstruation was not considered a sufficient indication. There must be a distinct pathological change in the sexual organs. Spencer Wells remarked that he should as soon castrate a crazy man, as to remove healthy ovaries for nervous disorders.

DR. JOHN HOMANS said that he did not know why removal of the testicles might not be warranted in certain cases of insanity, for instance the murderer who has cut up the genitals of his victims. There appears to be something erotic about his insanity.

DR. C. F. FOLSON said that, in his opinion, we are not yet in a position to say in precisely what cases removal of the ovaries is likely to prove of sufficient benefit to justify the operation. It has been done a considerable number of times, but probably with less benefit, on the whole, than is claimed for it. He had seen several cases where Tait's operation had been suggested, but only one where he could advise it. That was a case of profound hysteria, perhaps more properly called hysterical insanity and was one of those, he presumed, already referred to by Dr. Homans. Every other method of treatment which promised anything had failed, and for a dozen years the patient had been wretched herself and the source of the greatest discomfort to those with whom she was thrown in contact. She has remained for nineteen months since the operation quite well, a comfort to her friends and a useful member of society. In this case the physical health was good and there was no disease of the ovaries or tubes. In some cases the operation had done harm.

DR. S. G. WENNER had had one of Dr. Homans's patients at the Nervine Asylum where she was treated for neurasthenia, headache, backache, and dysmenorrhœa. She partly recovered, but the symptoms returned after an illness, and worse than before, with symptoms of hystero-epilepsy. He is glad that the operation was done.

—A trained nurse can often be of great assistance to the physician. On one occasion recently, it having been vainly tried to obtain a specimen of the urine from a comatose male patient, the young training-school nurse, on the morning after her arrival, presented triumphantly to the physician the desired specimen, having evidently seized in the nick of time upon the natural channels for yielding the desired secretion, in fact, having taken methods into her own hands. A well-equipped nurse is always ready to lay hold of the horn of a dilemma.

## Recent Literature.

*Topographical Anatomy of the Brain.* By J. C. Dalton, M.D., Professor Emeritus of Physiology at the College of Physicians and Surgeons, New York. Philadelphia: Lea, Brothers & Co. 1885. Vols. I. and II.

The work before us marks an epoch in American medical literature. Its author is eminently fitted for the undertaking. He has great knowledge, much manual dexterity, and above all clear ideas and the power of expressing them concisely. All prophesy its success. Briefly stated, the plan of the work is to show the structure of the brain, as far, that is, as it can be seen by the unaided eye, by means of sections in the three chief planes, to reproduce these by photographs and to multiply them by the heliotype process. Besides the sections there are some views of the surface of the brain. These illustrations, are admirable. Some indeed are better than others, but the worst would be good in any other company. Indeed there are but two or three that do not quite satisfy us, while we can hardly say enough in praise of most of them. Each plate, moreover, is accompanied by an outline drawing on, or below, which are the necessary explanations.

It is no easy matter under any circumstances to make fine sections of the brain. Hence the author's ingenious method may prove interesting, and a part of it shall be given nearly in his own words: The fresh brain supported by the calvaria is immersed, with the base upward, in a fluid of a little less than its own specific gravity. The saline solution above mentioned (sodium chloride solution sp. gr. 1.026), mingled with a small quantity of glycerine, is the most serviceable for this purpose. The ventricular cavities are then injected with a warm solution of gelatine by means of a fine cannula introduced into the infundibulum, which should be preserved entire for that purpose. The injection should be continued until the ventricles are moderately filled and the gelatine begins to exude between the crura cerebri and the hippocampal convolution; after which the brain is placed in a refrigerator and the gelatine allowed to solidify. This secures the normal condition of the internal parts.

The next operation consists in imbedding the brain in a mass of gelatine, of about its own consistency, in a metallic framework so constructed as to allow of successive sections in the horizontal or vertical plane. The arrangements for cutting the sections were not quite the same for the different series, but we have no space for the details. In cutting, the knife and the section were flooded with equal parts of glycerine and water. The sections were allowed to remain for twelve hours in a refrigerator immersed in the saline solution before being photographed.

Dr. Dalton gives a general description of the convolutions before plunging in *medias res*. It is already familiar to those acquainted with his writings. We will discuss it no further than to express a regret that so little is made of the occipito-parietal fissure on the convexity of the brain. True, it is

not a prominent feature, but it is always visible and is useful as at least hinting at the anterior boundary of the occipital lobe. No one can read this description without being struck by the facility with which so complicated a matter is handled. Whether one fully accepts Dr. Dalton's views, or not, one at least is perfectly clear as to what those are.

The above account of methods and description of the convolutions are in the introduction; we now come to Series A, which fills the rest of the first volume. There are ten plates showing the surface of the brain and several longitudinal vertical sections. The second volume is entirely devoted to Series B, which is a regular succession of fourteen horizontal sections in regular order from above downward with an extra-serial plate in addition. We gather that the third volume is to treat of transverse vertical sections. It is evident that Series B gives a much more thorough demonstration than Series A, for in the former we follow with great interest step by step the gradual changes in the arrangement of the brain, studying the upper surface of each plate. But in Series A four of the ten plates represent the surface of the brain (one with the cerebellum removed), which leaves but six for the interior. In these the method is sometimes adopted of representing both the surfaces exposed by a single cut, which, except in the case of the median section, seems to us less satisfactory than regular progression. It is, however, hardly fair to dwell on this criticism before the whole work has appeared. There are some simple diagrammatic wood-cuts in the text which are very useful in presenting certain points clearly. We have more than examined, we have studied this book, and have done so with profit as well as with interest. It is not meant for beginners, for whom much of it would be too difficult, but to one who has some knowledge of the brain and some experience, which is readily acquired, in interpreting sections, the work is of great value. One's ideas of the brain increase in breadth and clearness. Dr. Dalton's purpose being to write a topographical anatomy of the brain, he does not go into discussions on minute questions, though he may give his own views on disputed points: as on the origin of the external root of the olfactory nerve, which with Huguemin he traces to the gyrus hippocampi instead of to the insula according to Henle.

The binding is good and the type and paper very handsome. We understand that but two hundred copies are offered to the public. We should think there could be no doubt that unless a future edition is issued the book will soon become very scarce. It should be in the library of every one engaged in studying or in teaching the anatomy, and we may add the pathology, of the brain.

— Dr. Debove was awarded the Lacaze prize of 10,000 francs for his work on Tuberculosis. It was published as a series of lectures in the *Progrès Médical*.

— Dr. A. to Dr. B., discussing current magazine literature: "Now, I take *Life* every week." Dr. B., grimly: "I suspected as much."

# Medical and Surgical Journal.

THURSDAY, FEBRUARY 12, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by CUPPLES, UPHAM & CO., Boston. Price, 15 cents a number; \$5.00 a year, including postage.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUPPLES, UPHAM AND COMPANY,  
283 WASHINGTON STREET, BOSTON, MASS.

## RECENT RESEARCHES ON THE PATHOGENY OF SEPTICÆMIA AND PYÆMIA.

At the Medical College of Vienna, séance January 5th, Professor Weichselbaum stated present conclusions, as founded on recent scientific data, respecting the pathogeny of septicæmia and pyæmia. There is not yet, he said, entire agreement as to the definitive distinction between these two affections. In general, we understand by septicæmia a pathological condition characterized by putrid decomposition of the blood, and by pyæmia a malady caused by entrance of pus into the blood. The clinical distinction between them is based on the presence of metastases in pyæmia and their absence in septicæmia. Meanwhile, as metastases sometimes occur in septicæmia, a third mixed form has been established, called septicopyæmia.

Koch has produced in animals three kinds of septicæmia, differing from each other not only by their pathoanatomical forms but also by their microbes. The first, called vicious oedema, is identical with Pasteur's septicæmia; it may be engendered by introducing vegetable mould into the intestinal cavity of hares. The vegetable mould contains, in fact, the bacilli characteristic of this kind of septicæmia. These have a great similarity to the bacilli of malignant pustule, but they are more straight and rounded; they are never found in the blood; it has not been yet possible to make pure cultures of them.

The second species, analogous to the septicæmia of Davaine, may be produced in hares by the injection of putrid blood. The bacilli of this form of septicæmia have an oval form with rounded ends; the extremities take a deeper staining than the centre; they may be inoculated in birds and mice.

The third form, the septicæmia of mice, was produced by Koch by injecting putrid blood into the pleural cavity. The bacilli of this form are extremely thin; they are found in enormous quantities in the blood inside of the white corpuscles. The products of cultures have this form of volutes (certain gasteropod mollusks).

Pyæmia has also been obtained artificially by Koch by the injection of putrid matters; it is char-

acterized by numerous cocci partly isolated, partly united, into zoöglœæ.

In man the question requires to be studied anew. According to the actual state of things, we may say that there are two sorts of septicæmia: the one is a pathological condition produced by absorption of a putrid chemical poison, of the nature of ptomaines; the other is of bacterial origin. Just here we have to distinguish two subdivisions: the one pertaining to processes resulting from the pullulation of the bacteria of putrefaction, or of dead tissues (these bacteria cannot penetrate the living tissues, but they engender chemical poisons which may penetrate the organism); the second concerns processes due directly to microorganisms which invade the tissues and penetrate the blood. While the first subdivision comprehends all the different bacteria of putrefaction, the second is constituted solely by specific microbes. In pyæmia, Rosenbach, and after him Weichselbaum, have found and cultivated two sorts of coccæ, the pyogenic streptococcus and the staphylococcus aureus. The cultures of the first of these microbes develop very slowly at the ordinary temperature of the room upon meat peptone, while at a temperature of 37 to 38 C. these cocci multiply with great rapidity; they never liquefy gelatine; injected into animals they rapidly provoke extensive suppuration.

The second species of coccus takes on the appearance of berries; they develop very rapidly in meat peptone at the ordinary temperature of the room and liquefy gelatine, depositing themselves in the form of a brown sediment. These cocci have a great vitality. The staphylococcus aureus is not only found in pyæmia: it is also met with in a great number of phlegmons in furunculi, in acute osteomyelitis, in a certain number of acute abscesses. This fact is at first sight surprising, but it is easily explicable if it is remembered that in all these processes we have to do with a quantitative rather than a qualitative difference.

In phlegmons and certain acute abscesses are found, besides the two species of coccus mentioned, a third microorganism called staphylococcus albus, which is distinguished from staphylococcus aureus only by its color. All these phlegmons are not clinically identical. It seems that the phlegmons attributed to the streptococcus pyogenicus have the property of rapid extension, but they have little proneness to suppuration; while the phlegmons attributed to the staphylococcus aureus are limited in their extent, but have a great proclivity to suppuration.

Erysipelas is an inflammation of the skin which has a tendency to spread superficially, but which in general terminates neither in suppuration nor in necrosis. Fehleisen has found a specific coccus in erysipelas which has strong claims to be regarded as specific, and which is characterized by the follow-

ing properties: it is always found in the connective tissue and in the interstices of the superficial tissues, but never in the blood; it is always situated within the limits of the erysipelatous regions. Cultures of this bacterium develop rapidly in meat peptone; this coccus has deeply notched borders. With this microbe Fehleisen has produced erysipelas in animals by inoculation.

#### COLLECTIVE INVESTIGATION OF DISEASE BY THE MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

WE have received from a committee of the Pennsylvania State Medical Society a circular enclosing blanks for the collection from practising physicians of data regarding certain diseases, upon which a report is to be made to the Society at its annual meeting in May next. The committee, whose chairman is Dr. James Tyson, has adopted, for the sake of uniformity in the comparing of results, the same forms that were prepared by the similar committee of the British Medical Association. The subjects selected for investigation are three in number:—

I. ACUTE PNEUMONIA: with regard to (1) its epidemic prevalence, (2) its communicability, (3) its association with other prevalent diseases and with defective sanitary conditions, (4) its symptoms, duration, and result, (5) its treatment.

II. CHOREA: (1) its relation to rheumatism and other diseases, (2) the frequency with which certain accompaniments occur, (3) the common ailments to which those who suffer from it are liable, (4) the predisposing conditions and exciting causes, (5) its treatment.

III. ACUTE RHEUMATISM: with regard to (1) its antecedents, (2) the frequency with which certain symptoms occur, (3) the common ailments to which those who suffer from it are liable, (4) the climatic conditions with which it is associated, (5) its treatment.

In following the method of the English committee, the Pennsylvania committee has gone so far as to imitate the color of the different cards devoted to each disease. The cards are so prepared as to minimize the work of the reporters by allowing the answers to be given, as far as possible, through erasures of printed words rather than by writing in blank spaces; and a sample of a "filled-up card" is enclosed to show the method of procedure. By this means any practitioner who has made reasonably full notes of his case can with very little effort supply the information sought. We suspect that the chief difficulty will be to find physicians who in private practice have kept sufficiently full records of their cases to answer all the inquiries. But one good result will have been accomplished by this movement if physicians shall be led to more careful habits of observation and of record of the phenom-

ena which they daily meet. In the advantages to be gained by a collation and comparison of large numbers of such records there is much to be hoped. Our other State societies may well put the sickle to this same field.

#### A PROPOSED MEDICAL DIRECTORY OF THE UNITED STATES.

ANY one who has had occasion to consult the Medical Directory of Great Britain can hardly have escaped the wish that a similar directory of the United States were possible. Such a directory would certainly be a great convenience, but it needs to be issued under the supervision and by the authority of some responsible body. Probably the time will come when such a work will be undertaken by the American Medical Association.

We can scarcely believe that a directory issued in accordance with the following circular would meet with the confidence of physicians:—

"DEAR SIR,—We are preparing a Medical and Surgical Directory of the United States, a prospectus of which we enclose, and shall be much obliged if you will fill up the enclosed postal card with the information desired, and return same to us. As you will see, it is the intention to give the college and class of graduation of practising physicians, and in all cases where this does not appear after the name the presumption will be that such physician is *not* a graduate of any medical school. We therefore trust you will favor us with a reply at once, as in the event of not hearing from you your name will appear in the work on the same footing as those who PRACTISE WITHOUT DIPLOMAS."

#### MEDICAL NOTES.

—The *Annals of Surgery*, a monthly review of surgical science and practice, edited by L. S. Pilcher, M.D., of Brooklyn, New York, and C. B. Keetley, F.R.C.S., of London, England, has made its appearance. It is the only journal in the English language devoted exclusively to surgery; is published simultaneously in the United States and Great Britain, and aims to become an invaluable part of the library of every working surgeon. The first and second numbers give promise of success.

—One point incidentally raised in the controversy now pending in England over the question of overpressure in the public schools relates to the frequency of headaches in children. Dr. Crichton Browne went into some schools, and asked those children who suffered from headache to hold up their hands; and he adduces the large proportion who did so as some evidence of the existence of overpressure in those schools, quoting Sir Richard Owen to the effect that if more than five per cent.

of children suffer from headaches, there must be something wrong. The method of obtaining this information is certainly open to criticism, and perhaps Sir Richard Owen's "normal proportion" of headaches (to use a Hibernicism) is not quite reliable. A writer in the *Medical Times* (November 29) asked the question of a number of hospital patients (excluding all who were at the time suffering from diseases involving headache as a symptom, as well as all in whom headache was admitted as having followed intoxication or other definite occasional cause). Out of the total of 162 patients 42.6 per cent. suffered more or less from recurrent headaches. Of the total number questioned 12.9 per cent. had suffered from headaches as long as they could remember, but information as to the age at which the headaches began was only obtained in less than half the cases. Taking the lowest enumeration, that of Liveing, as representative, it would seem that a third of the people who suffer from headaches begin to do so before they reach the age of ten. Applying this to the percentage obtained by this investigator, he concludes that, taking boys and girls together, about fourteen per cent. of all school children might be expected to suffer from headaches.

—Mr. Henry Lomb, of Rochester, N. Y., has offered through the American Public Health Association the sum of \$2,800, to be awarded as first and second prizes for papers on the following subjects: 1. "Healthy Homes and Foods for the Working Classes"—first prize, \$500; second prize, \$200. 2. "The Sanitary Conditions and Necessities of School-Houses and School-Life"—first prize, \$500; second prize, \$200. 3. "Disinfection and Individual Prophylaxis against Infectious Diseases"—first prize, \$500; second prize, \$200. 4. "The Preventable Causes of Disease, Injury, and Death in American Manufactories and Workshops, and the Best Means and Appliances for Preventing and Avoiding them"—first prize, \$500; second prize, \$200. All essays written for the above prizes must be in the hands of the Secretary, Dr. Irving A. Watson, Concord, N. H., on or before October 15, 1885. The judges will announce the awards in the second week of December, 1885, at the annual meeting of the American Public Health Association. Competition is open to authors of any nationality, but all the papers must be in the English language. The American Public Health Association earnestly appeals to those able to compete to take part in this work, which it is believed will do much to augment the health, comfort, and happiness of the people.

—In Vermont a Frenchman, aged about forty years, while suffering from delirium tremens, a few weeks ago jumped unperceived from a train running at the rate of thirty miles per hour. It was night, and the thermometer was 30° F. below zero. He lay for seven hours, when he was discovered by

the trainmen, without underclothing or hat, and his dress consisting merely of a light suit, with cotton socks and a cheap pair of shoes. Both hands and feet were badly frozen, and he was considerably bruised by his fall. The hands were amputated at once, and a week later both feet were taken off at the ankle. Strange to say the man has rallied from the enormous shock, and bids fair to make a complete recovery.

—Louise Michel, the well-known Parisian socialist, is reported to be suffering from great nervous restlessness, hallucinations, and constant terror of being attacked by troops. She is therefore to be transferred from prison to a *maison de santé* for appropriate treatment.

#### NEW YORK.

—Dr. E. S. Gaillard, for many years editor of the *Richmond and Louisville Medical Journal*, and afterward of *Gaillard's Medical Journal*, died at his residence at Ocean Beach, New Jersey, on February 1st. He joined the Confederate Army in 1861, and lost his arm at the battle of Seven Plains. In 1863, he was made Inspector-General of Confederate Hospitals, and at the end of the war took up his residence in Richmond. He removed to Louisville in 1868, and in 1874 established the *American Medical Weekly*. Three years later he came to New York.

—Dr. John N. Packard read the annual address before the Academy of Surgery at its regular meeting on the 5th instant, taking a historical retrospect of the really great advances in surgery. These he enumerated as follows: (1) The introduction of amputations; (2) The ligature to check hemorrhage after wounds or amputations; (3) Excisions of joints; (4) Subcutaneous surgery; (5) Ovariectomy; (6) Anæsthesia; (7) Operative measures for relief of intra-thoracic affections; (8) Lithotrity and litholapaxy; (9) Antiseptic surgery, which is still *sub judice*; (10) The various operations in special departments as iridectomy, laryngeal surgery, etc. He concluded with a tribute to the late president of the Academy, Professor S. D. Gross.

—The annual meeting of the Hospital Saturday and Sunday Association was held at St. Luke's Hospital January 19th, when it was announced that the collection this year had so far amounted to \$30,988.90, and that enough more had been promised to insure a total of at least \$36,000. Last year the sum raised was \$13,062.71. The treasurer said that the trade auxiliary associations have done better this year than ever before, in spite of business depression; the falling off being principally in the churches—presumably because Hospital Sunday was rainy. The president, Mr. Miller, informed the Association of a project for a fair, under the management of benevolent women, to raise money for free hospital beds for sick saleswomen.

## Correspondence.

## LETTER FROM OUR LONDON CORRESPONDENT.

LONDON, January 22, 1885.

SINCE my last letter, the columns of the *Times* have contained a lengthy and very wordy correspondence on the too vexed question of the rightness of vivisection. I would not venture to attempt to apprise the value of the very opposite views which have been vehemently, and with no rigid regard to facts, expressed by the *Times* correspondents. Your readers will find fair samples of the discussion in the *Times* for January 16th.

It is of more importance, though not a material argument on behalf of the antivivisectionists, that Dr. Hughes Bennett's patient ultimately succumbed, though, without doubt, his symptoms and prospects of life were very significantly improved by Mr. Godlee's operation, at which a solid tumor of the brain was removed from below the surface of the convolutions through an aperture formed by taking out three crowns of trephine. But it will be more useful to leave your readers to digest the full details of this very interesting case when it shall be come to be published *in extenso*.

On Saturday last, in King's College Hospital, Sir Joseph Lister trephined over, incised, explored, and evacuated several drachms of fluid from the right frontal lobe of one of Professor Ferrier's patients. The man, a gardener, aged forty-two, was admitted to the hospital a month previously, when the principal morbid symptoms were total absence of hair on his head and face, left hemiplegia, double optic neuritis more marked on the right side, a suspicion of right proptosis, almost complete coma, with occasional intermissions during which the patient was partially sensible and at times able to answer a few simple questions, though he passed all his excreta unconsciously. Very firm pressure on the scalp over the right frontal lobe always elicited very marked expression of pain, and, when most sensible, he always complained of his head, and frequently put his right hand to his head when not able to speak.

His history showed that he had formerly grown an abundance of hair on his head and face; that his illness manifested itself between two and three years ago by an entire loss of his hair, followed by some slight failure of vision. He next noticed some loss of power in his left arm and leg. Last August he could no longer walk without the aid of a stick and suffered severely from headache. In November he finally took to his bed.

Iodide of potash had been freely tried with negative result, and there was no corroboration of the suspected syphilitic clue to the case.

During the few weeks that Professor Ferrier observed the man in King's College Hospital, it was noted that there was occasional partial dilatation with complete inaction of the right pupil, also that the movements of the right eye were sluggish and disproportionate to those of the left. The swelling of the right optic disk was greater than

that of the left, inasmuch as direct ophthalmoscopy showed three dioptres of hypermetropia for the former and only two for the latter. The man's condition grew worse and a fatal issue was the only prognosis without operative measures, such as were practised on Saturday last.

Then, after removing a crown of trephine at a point indicated by Dr. Ferrier, the dura mater was incised, and immediately the non-pulsating brain-substances rose through the trephine opening to the level of the external surface of the cranium, which was unusually thick and compact at this situation. Before the dura mater was opened, and again when the brain-substance was exposed, Sir Joseph Lister remarked upon the sensation of fluid which it returned to his digital examination. I learn from Professor Yeo, who was the conjoint operator in Ferrier's experiments on monkeys' brains, that it is usual for the living brain to return such a sensation under digital examination.

Before proceeding to enlarge the cranial opening, the operator incised the presenting brain-substance, and introduced the terminal phalanx of one finger, with which he said he felt a firm resisting body nearly one inch downward and backward from the centre of the trephine opening. Professor Ferrier denied himself the satisfaction of a digital exploration when Sir Joseph remarked that, while only his own fingers approached the wound, he only was responsible for its subsequent behavior, whereas the responsibility would be different were other fingers to explore in the wound. While repeating his digital exploration, but without introducing his finger further than before, the operator felt the before-mentioned resistant body yield and immediately there was a gush of very pale fluid, and subsequently the finger failed to detect the resisting body. On removing the finger immediately after the fluid escaped, the brain surface was observed to be pulsating properly and to have receded to a normal depth within the cranium. After adjusting the lips of the dura mater and scalp wounds in position a complete gauze dressing was applied which enveloped both eyes and the greater part of the head. The same afternoon the man asked for food; on Monday he was more sensible than he had been since his admission; indeed, he was cautious, discriminating about his food, and asked for a bed-pan for the first time since his admission to hospital, while there was distinct evidence of deterring sensibility and motor power in the left leg and arm. The wound has been dressed daily; a hernia cerebri which was manifest at the second dressing has yielded to gentle pressure.

To-day there are symptoms indicative of a further development of the original brain disease, which it is feared must be regarded as beyond the operator's reach. Nevertheless the experience afforded by such cases, even though a fatal issue ensue, will demonstrate the utility of trephining upon well-grounded indications in the hope that the cause of compression as well as the actual compression may be found at, and removed from, the accessible non-vital situation diagnosed from the symptoms read by the light of recent research into the localization of brain functions.

## LETTER FROM LIBERIA.

MONROVIA, LIBERIA.

MR. EDITOR, — Please pardon my seeming presumption in requesting a space in your scientific and highly reputed journal. But being possessed with that same charitable spirit that characterizes all worthy physicians, namely, to endeavor to find out what are the best remedies to relieve suffering humanity and disease, I feel impelled to lay before my professional brethren, for their consideration and professional criticism, some few facts in relation to certain medical herbs and plants. For a long time I have been impressed with the fact that nature must have provided drugs fully suitable for every disease peculiar to every climate. Hence, she has provided drugs in this our tropical climate singularly beneficial for the many diseases of our West Coast. With such convictions firmly established, I have made certain examinations and inquiries into the real worth and nature of certain medical herbs and plants as here used by the native practitioners, and in so doing I have been wonderfully and agreeably surprised at the ready relief which some of these plants have procured in their natural form. This led me to endeavor to reduce some of them to extracts and tinctures, which afford me a far better opportunity of getting at the real physiological effect and active force of the drugs, their maximum and minimum doses, etc. I have thus far discovered as powerful a drastic cathartic and anthelmintic as were ever brought into use; in addition to this I have obtained milder laxatives, astringents, and anodynes. It is quite surprising how many eminent physicians we have had here, not any one of whom would give a small portion of their time to the investigation of these useful plants. This climate must produce a change in the system and constitution of individuals coming from more temperate climates to this miasmatic region of Western Africa. In the dreaded African fever, which I have found to be nothing more nor less than the malarial or miasmatic fever, which is prevalent in all new and marshy countries, the medicinal plants which I have used in numerous cases which I have had in hand have never failed in subduing the fever in far less time than double doses of imported diaphoretics or diuretics or any class of drugs I have ever used. It is certain that very many useful drugs that are imported here in a very short time become inert and worthless, whereas drugs that are indigenous remain in the pure state for months and years; thus the *bolah*, a drastic cathartic, the *pachi*, a vermifuge, *cassin*, and several others with which I am acquainted, are known to retain their official properties for years. I have used barks of this country which, for their tonic and stomachic effect, far exceed gentian, quassia, and other barks. These latter drugs, tonics, etc., have been known here to deteriorate even when sent in form of powders in glass jars, thus showing their unreliability for general use in this country. It is even surprising how soon extracts and powders deteriorate in this climate, thus showing again how soon they must become inert. These facts can be substantiated by the surgeons of Freetown and other British hospital posts on the West Coast. I should, indeed, be happy if our professional brethren on the coast would give

the subject of our drugs and medicinal plants more attention and a fair trial in their practice. I would be pleased to receive any assistance which can be forwarded in the way of periodicals through you on the subject of tropical drugs or medicinal plants of the West Coast of Africa, as I would like to compare the different results of others, which I think would be of importance and benefit to our profession.

With best wishes for the Boston journal's success and prosperity, I have the honor to subscribe myself, yours respectfully,

J. HENRY ROBERTS, B.S., M.D.

## Miscellany.

## LETTER FROM DR. O. W. HOLMES TO DR. FORDYCE BARKER.

THE following letter from our honored *confidère* and fellow-townsmen, Dr. O. W. Holmes, to Dr. Fordyce Barker was read at the late meeting of the New York Academy of Medicine, at which Dr. Barker resigned the office of President after holding it for five years. His valedictory address appears on another page.

Dr. James R. Chadwick read the letter and presented a photographic portrait of the writer.

BOSTON, February 4, 1885.

MY DEAR DR. BARKER, — You must allow me to join my best wishes to those of the friends who will surround you as you take leave of the office which you have filled so ably and happily. I trust that you have not forgotten the day when you were with us at the opening of our Boston Medical Library. I know full well that we remember your presence, and how much it added to the pleasure of the occasion. Our Library Association, I hardly need tell you, has proved eminently successful. I want to say because you smiled upon its birth, but I dare not; for you have smiled upon a great many births, not every one of which, perhaps, has had the good fortune of the infant institution which you joined us in welcoming.

You may have learned some of our secrets during that visit, who knows? There are sparks of intelligence still left among us. At any rate, ever since you left Boston we have kept an eye upon you. As soon as it was learned that you had been spending some little time here, you were made President of the New York Academy of Medicine. As soon as you got back, for *some* reason, the Academy took a new start and has been flourishing ever since. All my informants agree about the fact, and they add that it is due to your own faithful administration and energetic efforts.

We of Boston congratulate our brethren of New York that they have had the great advantage of your services during these last eventful years. The gratitude of the medical profession will keep alive the memory of its past benefactors. We must trust the future for its *vis-à-fronte*, but in the broadest and loftiest period of progress the leaders will look back to the days of up-hill work when you, our honored friend, lent all your vigor to that *vis-à-fronte*

which they will feel pressing them forward to larger and higher achievements.

Pardon me for addressing this open letter to you. You can retire "to blush unseen" while some friend is reading it, if it is thought worthy of that honor.

Always faithfully yours,

OLIVER WENDELL HOLMES.

To DR. FORDYCE BARKER, President of the New York Academy of Medicine.

#### GENERAL GORDON FROM A MEDICAL POINT OF VIEW.

GENERAL GORDON'S life is as great a mystery as his character. His physical endurance in the desert would be difficult to understand in a strong man; but in a man with angina pectoris, and with a horror of meals, it is simply a kind of miracle. As far back as November 15, 1878, and in that very Khartoum on which the eyes of all Christian nations are turned, he writes: "There are not nine Europeans in the Soudan, and they vegetate and do not live. Can you conceive what it is never to have any desire to eat? That is my case. I hate the operation. . . . My angina pectoris has not troubled me lately. According to medical books it is not known what occasions this. It is heart disease, and makes you think you are on the brink of death. A rush of blood takes place to the heart, and you think all is over. I may say I have died suddenly over a hundred times." We can only find encouragement in such facts to go on hoping that against all human and medical probabilities Gordon will again emerge from the Soudan, and long continue to show the world what can be done by men with grave disease, but with faith in their own mission and in God's providence. — *London Lancet*, June 21, 1884.

#### THE "UNCONTROLLABLE" VOMITING OF PREGNANCY.

A PAPER on the above subject by Dr. Graily Hewitt, read before the Obstetrical Society of London, is summarized in the *Medical Times* (November 22). Its conclusions are based upon two series of cases in which the condition of the body and cervix were recorded, and are as follows: —

(1) That the cases in which the disease is due to some other organ than the uterus are so few in number (only one in the series of 32) that they may be almost excluded from consideration. (2) That in the large majority of cases the disease presents itself during the first half of pregnancy. (3) That the evidence points to interference with the normal expansion and growth of the gravid uterus as the condition of the production of this dangerous affection, and that this is most frequently brought about by or in connection with retention of the bulk of the uterus in the bony pelvis, in 88 per cent, the uterus being ante-flexed or anteverted, and in 12 per cent, in a state of retroversion, the other conditions met with being hardness, resistance, or unusual rigidity of the os and tissues of the cervix. (4) There appear to be two factors to be considered capable of interfering with the expansion of the uterus (a) incarceration with flexion or version;

(b) undue hardness, and rigidity of os and cervix. These may be conjoined in a given case. It appears to be borne out by the facts recorded that the incarceration is the more important of the two factors, as a rule at least. The facts appear to point to the occurrence of embarrassment in the expansion of the uterus very early in the pregnancy, such as might be expected to be occasioned by a previously flexed state of the uterus or by a congested indurated state of the cervix, or by the two conditions combined. As the pregnancy advances, the congestion and swelling are intensified, and the resistance to expansion thus increased. It appears probable that the particular cause of the sickness observed is the compression of the nerves situated in the tissues which are especially exposed to compression, namely, those around the cervix uteri, and especially those near the internal os. Copeman's success in the treatment of severe sickness by dilating the internal os is evidence in this direction. The importance of the flexion element has been denied, one principal objection being that sickness is not always present when the uterus is flexed. But the case is the same in the non-gravid uterus; severe sickness is not seldom due to flexion of the non-gravid uterus, while flexions are observed without sickness. Corroboration of the author's views are contained in Gehrung's recent paper. As a rule, severe sickness is limited to the first half of pregnancy, in a very few cases it persists longer; in these rare cases, the cause may be rigidity of the tissues round the internal os, persisting to a late period. As regards treatment, the first indication is to secure the normal upward movement of the fundus uteri, to relieve the incarceration of the uterus, when present, if that be possible, and to prevent its occurrence by a properly arranged method of treatment. Absolute rest in the supine position if anteversion be present or on the face or side if retroversion be present, and the use of the knee-elbow position will be required. These measures suffice in many cases. If the uterus be fixed, gentle continuous pressure must be applied internally by the fingers, or by an air-ball, and the position maintained by a suitable pessary. These measures failing, Copeman's procedure of dilating the cervix should be employed. Artificial abortion, will, it is believed, be rendered unnecessary if the less severe measures are applied early.

#### CARLSBAD IN FORMER TIMES.

THE springs of Carlsbad which for more than five centuries have been sought by the valetudinarians of Europe were formerly given a much more prominent part in the treatment of resident invalids than they now are. A recent article in *The Nineteenth Century* quotes an author, Dr. Summer, writing in 1571, up to which time the waters had been used almost wholly externally. The patient was made to spend from ten to eleven hours per day in the bath, in three or more sessions. The object was to excite a cutaneous eruption whereby "the evil humors may flow out." It is suggested that for people who never wash in health a thorough bath may have a pretty strong systemic influence. Certainly it will not be denied that eleven hours

of bath a day would have a considerable effect of one sort or other on any one short of a merman. The North American Indians, it is said, who seldom wash when well, betake themselves when ill to the hot springs of Colorado and New Mexico and lie in them for hours together.

After two centuries or more of bathing, the waters began to be drunk; and then, too, the amounts used were not niggardly. Fifteen to eighteen glasses per day was a starter, and the number was quickly carried up to thirty or forty.

A medical visitor in 1756 records that he himself drank from fifty to sixty glasses in the course of two hours. Peter the Great, perhaps from his being a czar, was ordered to begin with only three glasses. But he understood the direction to mean pitchers, and manfully emptied two, but was obliged to acknowledge himself vanquished before the third. A chalk tally still preserved on a board in his room, only partially legible, shows one day's achievement to have been twenty-three glasses.

## REPORTED MORTALITY FOR THE WEEK ENDING JANUARY 31, 1885.

Deaths reported 2,597; under five years of age, 886; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrheal diseases) 137, lung diseases 131, consumption 102, diphtheria and croup 139, scarlet fever 63, measles 60, typhoid fever 18, diarrheal diseases 24, erysipelas 18, whooping-cough 16, cerebro-spinal meningitis 14, malarial fever 9, puerperal fever 4. From *typhoid fever*, Philadelphia 15, New York 7, Baltimore and Cincinnati 6 each, Chicago 5, Brooklyn 4, Boston, District of Columbia, New Haven, Nashville, and Lynn one each. From *diarrheal diseases*, New York 15, Cincinnati 4, Baltimore and Nashville two each, Brooklyn, District of Columbia, and New Haven one each. From *erysipelas*, New York 9, Philadelphia, Chicago, and Boston two each, Baltimore, Lowell, and Taunton one each. From *whooping-cough*, New York 6, Brooklyn, Boston, and District of Columbia two each, Philadelphia, Chicago, Baltimore, and Springfield one each. From *cerebro-spinal meningitis*, New York 5, Holyoke three, Chicago two, Lowell, Fall River, Springfield, and Newton one each. From *malarial fever*, Baltimore three, New York, Philadelphia, and Brooklyn two each. From *puerperal fever*, Chicago 2, Boston and Nashville one each.

In 110 cities and towns of Massachusetts with an estimated population of 1,336,112 (estimated population of the State 1,355,-

104), the total death-rate for the week was 15.09 against 18.54 and 18.37 for the preceding two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,906,116, for the week ending January 17th, the death-rate was 24.2. Deaths reported 1,127; infants under one year of age 828; acute diseases of the respiratory organs (London) 522, whooping-cough 108, measles 70, scarlet fever 59, diphtheria and croup 34, fever 28, diarrheal diseases 21, small-pox (London 47, Liverpool 2, Birmingham one) 50. The death-rates ranged from 16.0 in Hull to 32.8 in Cardiff; Birmingham 25.8; Blackburn 29.7; Bradford 20.9; Leeds 22.1; Leicester 21.5; Liverpool 21.5; London 23.7; Manchester 29.7; Norwich 25.7; Nottingham 20.2; Sheffield 20.8; Sunderland 23.3. In Edinburgh 22.5; Glasgow 31.5; Dublin 31.9.

For the week ending January 10th, in the 885 cities, there were 54 deaths from consumption, lung diseases 37, diarrheal diseases 16, diphtheria and croup 7, puerperal fever 7, measles 6, small-pox 4, typhoid fever 3, scarlet fever 1, erysipelas 1. The death-rates were: at Geneva 11.2; Zurich 3.9; Basel 12.4; Bern 31.1.

For the week ending January 17th, lung diseases 30, consumption 27, diphtheria and croup 13, measles 5, whooping-cough 1, typhoid fever 3, scarlet fever 2. The death-rates were: at Geneva 23.3; Zurich 15.5; Basel 21.9; Bern 28.1.

The meteorological record for the week ending January 31st, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps:—

Date.	Barom-eter.	Thermometer.			Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JANUARY 31, 1885, TO FEBRUARY 6, 1885.

WATERS, WM. E., major and surgeon. Granted leave of absence for one month, S. O. 24, Department of the East, January 31, 1885.

TAYLOR, B. D., captain and assistant surgeon. Granted leave of absence for one month, to take effect between March 15 and April 1, 1885. Permission to leave department limits, S. O. 10, Department of Texas, January 26, 1885.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, JANUARY 1 TO 31, 1885.

STONER, G. W., surgeon. When relieved to proceed to Washington, D. C., for duty as chief of Purveying Division, January 16, 1885.

BENSON, J. A., passed assistant surgeon. When relieved to proceed to Chicago, Ill., for duty, January 12, 1885.

CARMICHAEL, D. A., passed assistant surgeon. When relieved to proceed to Cairo, Ill., for duty, January 3, 1885.

AMIS, R. P. M., passed assistant surgeon. When relieved to proceed to New York, N. Y., for duty, January 14, 1885.

FRIGHT, F. M., passed assistant surgeon. To proceed to Norfolk, Va., and assume charge, January 12, 1885.

BROOKS, S. D., assistant surgeon. To proceed to Evansville, Ind., and assume charge, January 14, 1885.

CARRINGTON, P. M., assistant surgeon. To report to surgeon in charge, St. Louis, Mo., for temporary duty, January 17, 1885.

#### PROMOTION.

STONER, G. W., surgeon. Promoted and appointed surgeon by the Secretary of the Treasury, from January 16, 1885, January 14, 1885.

#### APPOINTMENT.

CARRINGTON, PAUL M., M.D., of Georgia, having passed the examination required by the regulations, was appointed an assistant surgeon by the Secretary of the Treasury, January 16, 1885.

#### SOCIETY NOTICE.

SUFFOLK DISTRICT MEDICAL SOCIETY, SPECIAL UNION MEETING. By courtesy of the Boston Society of Arts and Gen. L. A. Walker the Section for Clinical Medicine, Pathology, and Hygiene, in conjunction with the Boston Society of Architects, will meet at the Massachusetts Institute of Technology on Monday, February 10th, at 7.15 o'clock. Mr. J. Pickering Putnam will read a paper upon "The Principles of Sanitary Plumbing," illustrated by improved sanitary appliances devised by the lecturer and others. Apparatus will be exhibited showing the action of water-pipe siphonage. Dr. Walcott, of the Massachusetts State Board of Health, Prof. T. M. Clarke, of the Institute of Technology, Mr. L. S. Philbrick, Mr. E. W. Bowditch, Dr. G. B. Shattuck, Dr. C. F. Folsom, members of the Boston Board of Health, A. H. French, and others are expected to take part in the discussion.

A. N. BLODGETT, M.D., Secretary.

SUFFOLK DISTRICT MEDICAL SOCIETY. *Obstetric and Gynecological Section.*—There will be a meeting of this Section at 19 Bayston Place on Wednesday, February 18, 1885, at 7.45 P. M. The following papers will be presented: Dr. John Homans, "Nine Cases of Removal of Uterine Tumors by Laparotomy." Dr. John L. Sullivan, of Malden, "Several Cases of Imperfect Abortion." It is needless to say that this meeting cannot be other than one of the most interesting of the season.

JAMES R. CHADWICK, M.D., Chairman.  
ROBERT B. DIXON, M.D., Secretary.

CORRECTION.—Journal of 5th inst., page 127, first column, last line but one, for "subnitrate of bismuth is worse," read subnitrate of bismuth is inert.

#### BOOKS AND PAMPHLETS RECEIVED.

The Sanitary Engineer. A Journal of Civil and Sanitary Engineering, and Public and Private Hygiene. Vol. X. June to November, 1884.

The Hygiene of the Nervous System and Mind, etc. By C. H. Hughes, St. Louis, M.D. (Reprint from the *Alienist and Neurologist*, January, 1885.)

Verträge, Untersuchungen über die Natur und Wirkung der Oleate. Von John V. Schneider, A.M., M.D., in Philadelphia. Weiterer untersuchungen Physiologische Wirkung der Oleate. II. III. Separat Abdruck aus "Monatsschrift für Praktische Dermatologie," iii. Band, 1884.

The Revival of Ovariotomy and its Influence on Modern Surgery. An Address delivered at Birmingham November 5, 1884, by Sir Spencer Wells, Bart. Second Edition, with Additional Notes. London: J. & A. Churchill, 1885.

Cases of Disease of the Frontal Sinus. (Reprint from the Transactions of the American Ophthalmological Society.) 1884.

Thirty-seventh Annual Report of the Massachusetts School for the Feeble-Minded at South Boston. For the Year ending September 30, 1884. Boston: State Printers, 1885.

Transactions of the Obstetrical Society of London. Vol. XXV. For the Year 1885. With a List of Officers, Fellows, etc. London, 1884.

General Localization in Relation to Insanity, with Cases. By J. M. Carnochan, M.D. (Reprint from the *Medical-Legal Journal*.) New York: J. H. Vail & Co., 1884.

Annual Report of the Supervising Surgeon-General of the Marine-Hospital Service of the United States for the Fiscal Year 1884. Washington, D. C., 1884.

Quarterly Report of Medical Officers of the United States Army, with their Stations and Duties, as reported to the Surgeon-General, January 1, 1885. Washington.

A Useful Catheter for the Operation for Vesico-Vaginal Fistula. (Reprint from *Detroit Lancet*, December, 1883.) The Management of Pott's Disease of the Spine in Children. (Reprint from *Medical Age*, November 26, 1883.) By Hal. C. Wyman, M.D., Detroit, Michigan.

A Manual of Human Physiology, including Histology and Microscopic Anatomy, with special reference to the Requirements of Practical Medicine. By Dr. L. Landouzy. Translated, with additions, by William Stirling, M.D., Sec. D. With 176 Illustrations. Vol. I. Philadelphia: P. Blakiston, Son & Co.

A Guide to the Study of Ear Diseases. By P. M. Trible, M.D., F.R.C.P., Edinburgh, etc. J. H. Vail & Co., 1884.

## Original Articles.

THE RECENT INVESTIGATIONS CONCERNING THE ETIOLOGY OF CHOLERA.<sup>1</sup>

BY R. H. FITZ, M.D.,

Professor of Pathology in Harvard University.

In 1880, Professor Eichhorst, then of Göttingen, in a compact but comprehensive article on the subject of cholera, thus expresses himself: "Our assured knowledge of the essence of cholera is eminently little. After a long period of belief in a chemical substance or cholera-poison, the prevailing views of the present tend towards the idea that cholera is due to the action of lower vegetable organisms. It must be borne in mind, however, that these views are based rather upon the analogy of this disease to other infectious diseases than upon the absolute isolation of the fission-fungi and the discovery of their morphological characteristics."

It is unnecessary to state that the search for micro-organisms in connection with cholera is no task of the past two years, but has occupied the attention of investigators during the various epidemics which have devastated Europe. According to Hirsch, attention was first called by Böhm, in 1838, to the presence of cryptogams resembling ferment-fungi in the dejections and in the intestine. Not only in Germany but also in England, France, and Italy have repeated observations been made and by various persons. In 1873, Lewis and Cunningham, in India, searched for characteristic organisms in cholera and cultivated those found. The bacteria and vibrios contained in the stools presented no characteristics by which they might be distinguished from those to be seen in the feces of persons not suffering from cholera or from those occurring in putrid fluids.

The wonderful advances made in bacteriology during the past ten years, both in France and Germany, gave renewed hopes to the medical world that at last might be discovered the long-sought-for essence of cholera. When it was known that Robert Koch, whose name is so closely connected with nearly all the progress made of late years in our knowledge of the pathogenic importance of bacteria, was to lead the German commission for the investigation of cholera, it seemed as if the discovery were already made. Although the results of his work are presumably familiar to all of you, a discussion of the causes of the origin and of the promoters of the spread of cholera must necessarily be preceded by some statement of the factors to which he has lately called attention. This is all the more desirable in consequence of the repeated efforts which have since been made to control or confirm his observations.

A conference of German physicians assembled in Berlin, July 26, 1884, to listen to the statements of Dr. Koch with reference to the results of his investigations. He then presented a comprehensive and detailed account of the nature and bearing of his work. A full report of the proceedings was published in the *Berliner Klinische Wochenschrift*, and elsewhere, and soon made its way over the world in full or in abstract.

<sup>1</sup> Read before the Boston Society for Medical Improvement, February 9, 1885.

Nearly one hundred cases came under observation, including the results of sixty autopsies made in India and Egypt and of two at Toulon. The dejections of thirty-two patients in India and of two at Toulon were examined, and frequent investigations of vomit were made.

As might perhaps have been expected but little additional knowledge was obtained with regard to the pathological anatomy of cholera. The later European epidemics of the disease have enabled the most eminent pathologists of Germany and France to discover all that could be seen with the appliances in use at the time. The condition of the intestines, as described by Koch, corresponds very closely to that given by Eichhorst.

The alterations are limited to the small intestines and are most marked in the immediate vicinity of the ileo-cæcal valve. Eichhorst states that they may be continued into the upper part of the colon. The appearance of the mucous membrane varies in individual cases. In some there is apparently but little alteration, with perhaps slight redness, swelling, and dulness of the surface, and a prominence of the solitary follicles and Peyer's patches. In others the redness is greater, either diffused, in blotches, or limited to the edge of the follicles and patches. The microscope showed that this red margin corresponded to an invasion of bacteria, the now famous comma-bacilli. They were found in the canals of the cryptic glands, between flakes of detached epithelium and basement membrane, and at times deeper within the tissue.

In a third series of cases the lower part of the ileum is of a dark, reddish-brown color, and the mucous membrane studded with superficial hemorrhages. Necroses of the surface and diphtheritic patches of mucous membrane were seen in many instances. The comma-bacilli were also found in this series, and, in addition, various other bacteria, long thick rods and very slender rods, were present in the cryptic glands and their vicinity. The relations were such as are found in necrotic and diphtheritic alterations of the intestinal tract and in typhoid ulcers, where the tissue is first destroyed by pathogenic bacteria and then invaded by other non-pathogenic forms. The comma-bacilli always preceded the others and penetrated more deeply.

The statements of Koch with regard to the relation of the intestinal contents to the alterations of the wall are important. In those cases where the mucous membrane appeared least abnormal the contents were watery and slimy, or gruel-like, and contained the comma-bacillus, the more abundantly the less contaminated the contents. In the cases of hemorrhagic, necrotic, and diphtheritic enteritis, the contents bore no resemblance to rice-water, but were an offensive, bloody, ichorous fluid. Bacteria of the most varied sort were found in this fluid.

Although the comma-bacilli were constantly found in the intestinal contents, whether at post-mortem examinations or in those discharged during life, they were not discovered in the organs or in the blood.

It is evident from Eichhorst's description of the pathological anatomy of cholera that the examination of the rest of the alimentary canal, the brain, thoracic and abdominal organs, produces

chiefly negative results. The spleen, in particular, rarely shows any changes; likewise the liver. A cloudy swelling of all organs is mentioned. The kidneys are described as either pale, hyperemic, or fatty, and the convoluted tubules contain desquamated epithelium in part fatty, granular material, hyaline casts, and blood corpuscles.

The French commission (Strauss, Roux, Nocard, and Thuillier) described in considerable detail the condition of the kidney in cholera. Special attention was called to the occasional occurrence of disseminated patches of what appeared to be a necrosis from coagulation. The renal changes were regarded as degenerative rather than inflammatory, and as analogous to those occurring in other infectious diseases. This view and the reported appearances correspond with the condition of the urine after an attack of cholera, it being albuminous and containing blood and casts. The changes are temporary, however, a chronic nephritis being a rare result of cholera.

The French observers, furthermore, noted an acid reaction of the blood-serum. The knowledge of this post-mortem acidity of the blood led Cantani to test this fluid during life. He found that its alkalinity rapidly diminished during the stage of asphyxia, the reaction becoming neutral and eventually acid. He attaches especial importance to this observation, considering that a certain degree of alkalinity is necessary for the preservation of life, and that, in the treatment of cholera, acid hypodermic injections may prove of value in preventing a considerable diminution of this quality.

The presence of the comma-bacillus in the intestinal contents at the post-mortem examination of two acute and uncomplicated cases of cholera, there being neither hemorrhagic nor putrefactive changes, led Koch to investigate this organism.

His researches occupied a period of months, indeed may be said to continue at present, and were directed toward the discovery of its peculiarities and its possible relation to cholera. Its shape suggested the term "comma" bacillus, although its manner of growth, when cultivated, indicates that it is rather of the nature of a spirillum, like the spiral fibre of relapsing fever, than of a bacillary character.

It is claimed by Koch that this organism presents definite characteristics by which it may be distinguished from all other microorganisms. These include the peculiarities of shape and size, in addition to its behavior when cultivated under certain conditions. Without entering into all the details of its cultivation in various media, I will merely call attention to the method employed by Koch in demonstrating the presence of the bacillus in cases of cholera and in determining its identity. It is obvious that no criticism of Koch's work is likely to be of absolute value which does not reproduce these results constantly observed by him.

Demonstration. — A bit of mucus from the defecation or from the intestinal contents is spread smoothly on a cover-glass and dried. The glass, after being passed thrice through a flame of gas or alcohol, is covered with a watery solution of fuchsin or methylene-blue. After a few seconds it is washed, and may be examined at once with a one-

twelfth oil-immersion lens and an Abbé's illuminator.

Identification. — The microscopic examination alone suffices for diagnosis in only relatively few cases, for it does not often occur that a sufficient number of comma-bacilli are found to establish the diagnosis. For absolute proof it is usually necessary to cultivate the comma-bacillus. A very small bit of mucus is placed in ten cc. of warmed nutrient-gelatin. This material is composed of meat-water, pepton, and ten per cent. of gelatine, and has a feebly alkaline reaction. It is offered for sale in Berlin. The mixture is stirred with a sterilized glass rod, and poured upon a plate of glass which is placed horizontally upon ice. The gelatine soon sets, and a bell-glass is placed over the specimen, which is kept moist till the colonies develop. Two ordinary plates may be used instead of the bell-glass and glass plate. The colonies may be examined with a power of a hundred diameters.

The growth of the bacillus may take place within twenty-four hours, and the colonies assume a defined, characteristic shape, unlike that of any other variety of bacterium known to Koch. The very young colonies look like exceedingly pale, small drops, with an irregularly defined, scalloped, partly rough and jagged outline. They soon become granular and less homogeneous than other bacterial colonies. The granular appearance increases with the size of the colony, and the latter eventually appears as a collection of strongly refracting granules. The gelatine then becomes liquefied in the immediate vicinity of the colony, which sinks into the resulting funnel-shaped depression, and appears as a small white point at the bottom. This sinking of the colony is quite peculiar, occurring as described in very few varieties of bacteria, and is never so pronounced as in the case of the comma-bacillus. It is seen most distinctly in pure cultivations obtained from the gelatine plate. The gelatine in the test-tube is pricked with a previously heated platinum wire which has been stirred about in a suitable colony. The tube is then closed with a plug of sterilized wadding. As the growth progresses the funnel-shaped depression appears corresponding with the print of the wire. At the upper part is a deep hollow which, in the semi-fluid gelatine, resembles an air-bubble. In the cultivations of other bacteria there is no such a depression with the bladder-like space at the top.

The comma-bacilli thrive best at temperatures between 86° F. and 101° F., but grow at those above 60° F. A cultivation was frozen for an hour at a temperature of 14° F., and subsequently sown. No modification in the development and growth of the crop could be detected. Babes reports that water containing the bacilli, when boiled, becomes sterilized; that is, a temperature of 180° F. destroys the bacilli. The same effect may be produced by lower temperatures, although at 122° F. a feeble growth was evident. Under favorable conditions their increase is enormous within the first twenty-four hours, but after two or three days they begin to die. Koch states that when the transudation from the blood takes place into the intestine, the

comma-bacilli disappear and are replaced by other bacteria, especially those of putrefaction. He considers it highly probable that the former bacilli, if placed in putrid fluids, die rather than become properly developed, and calls attention to the significance of this view in connection with the subject of disinfection. The growth is most luxuriant in fluids free from acidity, which possess a certain concentration of nutriment. Some acids, as that in boiled potato, do not stop their growth, which readily takes place on the latter, and in broth, milk, and various articles of food. When dried they die, if in thin layers, in the course of three hours. They were never kept alive after drying for twenty-four hours, even when in thick layers. Every effort was made to ascertain the existence of a permanent state for these organisms; but, so futile were the attempts, that Koch declares it is useless to hope for the discovery of a permanent state of the comma-bacillus.

The first confirmation of Koch's observations with regard to the cultivation and development of the comma-bacillus was made by Nicati and Rietsch during the epidemic in Marseilles. I have been able to see merely a reference to their communication, written by Friedländer. A series of investigations concerning the comma-bacillus were made by Van Ermengem, and were reported by him to the Belgian Microscopical Society. His material was obtained at Marseilles from eight post-mortem examinations and from thirty-four patients. His confirmation of Koch's discoveries with reference to the appearances of the comma-bacilli and their behavior when cultivated is complete. Very recently Babes has published the account of an extensive series of experiments concerning the properties of the comma-bacillus, especially with reference to the effect of its surroundings when cultivated. In general, his work is confirmatory of that of Koch.

Before considering the relation of these organisms to cholera it may be well to refer to the criticisms called forth by Koch's communications.

In a report to the Director-general of the Army Medical Department, Lewis, who went to Marseilles during the epidemic there prevailing, examined numerous specimens of cholera-dejections, and found that comma-bacilli were more or less conspicuously present in all instances. He states, however, that "comma-like-bacilli identical in size, form, and in their reaction with aniline dyes, with those found in choleraic dejecta, are ordinarily present in the mouth of perfectly healthy persons."

In reply to this criticism, Koch states that he has long been familiar with the bacilli to be found in the saliva. There are certain differences in their appearance from those of the comma-bacilli, but the biological characteristics are more important for differentiation than the form. When cultivated, both varieties of bacteria are easily distinguished.

At the annual meeting of the Association of German Naturalists and Physicians, a communication was made by Finkler and Prior to the effect that they had found in cholera nostras a microorganism whose shape was identical with that of the comma-bacillus in Asiatic cholera. Its biological qualities, when cultivated, were regarded as absolutely the

same as those of the comma-bacillus as stated by Koch. They claimed to have discovered evidence of a spore-formation in the comma-bacilli of cholera nostras, which had not been established in like manner for the bacilli of Asiatic cholera. Klamann stated at the same meeting that he had also found in cholera nostras formations exactly corresponding with those shown. The statements of Finkler and Prior were criticized on the spot by Hueppe, formerly a worker in Koch's laboratory. He called attention to the differences in the appearance of the comma-bacilli of Koch and of those shown by Finkler and Prior. He also suggested that the cultivations of these observers were probably impure, as their statements concerning the development of the bacilli did not harmonize with those of Koch, whose investigations had continued over a longer period of time.

Ceci and Klebs, who investigated the pathology of cholera from material obtained at Genoa, declared that the comma-bacilli and spirilla of Asiatic cholera proved identical with the forms obtained by Finkler and Prior in cultivations from the faeces of cholera nostras. Klebs also stated that the same forms of spirilla were found in a case of pneumonia with diarrhoea.

Finally Klein and Gibbes, in their preliminary report of the English Cholera-Commission, deny that the comma-bacilli found in cholera, when cultivated, behave in any way differently from the putrefactive organisms.

Koch stated, in answer to the communication of Finkler and Prior, that their methods gave no security against the predominant growth of other forms of bacteria and the admission of impurities. One of their cultivations, said to be tolerably pure and obtained from a putrid stool, showed, when cultivated in gelatine, four different kinds of bacilli. Although one of these, when dried and stained, presented a certain resemblance to comma-bacilli, yet, in general, the individuals were thicker and longer. The growth in gelatine and on potatoes of the crooked bacilli of Finkler and Prior and that of the comma-bacilli of cholera showed marked differences. He had examined three cases of cholera nostras, two of which were fatal, but with negative results. He doubted whether the bacilli described by these observers came from the intestine, thinking they may have entered the putrid stool and the cultivation after the former had left the body.

While ascertaining the properties of the comma-bacilli, Koch learned that these organisms were constantly present in the intestinal contents from cases of cholera. He found them most numerous in the lower part of the small intestine where the most marked alterations of the wall were found. They gradually diminished in number above this region. In the most recent cases they appeared as nearly a pure cultivation, and were less numerous in the later stages of the disease, where the secondary changes in the intestine were more marked. The most careful investigation of all other organs than the intestine and of the blood failed to show anything which could be regarded as infectious material. A large series of controlling examinations were made both of corpses and of dejections

from the sick and well. Various substances rich in bacteria were also examined but with negative results.

Similar observations were made in Berlin after his return from India and with a like result. As late as the middle of November, in his reply to his critics, he states that hundreds of investigations have recently been made in the Imperial Health Office, but the presence of the true comma-bacillus has never been discovered. In his communication to the cholera-conference he affirms his positive belief that the comma-bacillus is a constant accompaniment of the cholera-process and is never found elsewhere. This opinion is even more absolutely presented in the article above referred to—the latest published by him; the comma-bacilli being regarded as specific bacteria, found only in Asiatic cholera.

During his researches in India numerous specimens of sewage and of water from tanks and rivers, also of water exposed to all sorts of impurities, were examined, without the detection of the comma-bacillus in any of the specimens.

In the report of progress last sent from India he calls attention to the discovery of the comma-bacillus in a water-tank, in the immediate vicinity of which a localized epidemic of cholera occurred. The garments of the first case of cholera, besmeared with dejections, were washed in this tank. A number of samples of water taken at different times and from different parts of the tank were cultivated in gelatine, and comma-bacilli were found in tolerable abundance in several of the earlier specimens. Toward the end of the epidemic only one of the specimens contained the bacilli and these were present only in small quantity.

(To be concluded.)

#### **GROUNDS FOR OBJECTING TO THE ROUTINE USE OF THE VAGINAL DOUCHE IN NOR- MAL CHILDBED.<sup>1</sup>**

BY Z. B. ADAMS, M.D., OF FRAMINGHAM, MASS.

I HAVE chosen, and thus formulated, my subject for two reasons: First, because I wished to excite discussion of an important question which could be fully introduced in a short paper; and second, to bring forward matter especially interesting and, as I believe, valuable to country doctors.

I am in the constant habit of employing monthly nurses drawn from the city, and it is probable the same practice is followed by others. Country nurses are not to be relied upon, and only very rarely are they entirely devoted to, or thoroughly trained in, the occupation of nursing, so that they are of little real use in the lying-in room.

Lately I have been annoyed to find that these city nurses required watching to prevent the indiscriminate and unauthorized use of the vaginal douche during the parturient week. They come equipped with the clinical thermometer, the catheter, the gored binder, the breast-pipe, and, lastly, the syringe and its accessories, all of which they proceed to use as if a matter of course. How soon

we shall have added the endoscope, the sphygmograph, the stethoscope, and a case of surgical instruments, I do not know. To none of the material of their present armamentarium do I see any valid objection; indeed, I highly approve of all these things, not excepting the syringe, provided they are intelligently used. But when I see these nurses preparing to use the syringe for the purpose of douching the vagina of a perfectly healthy parturient woman without saying by your leave, it seems to me proper to enter my protest, and so I do. The nurse who has taken the temperature and recorded it, noted the pulse and perhaps the respiration, adjusted the binder, attended to the function of the bladder, washed and dressed the baby, etc., etc., all without special direction or attention on my part, now looks up in surprise as if I were unwarrantably interrupting the performance of the usual offices of childbed when I ask what she is about to do with that syringe. And when I absolutely forbid its use for the purpose indicated I am treated as though I had expressed grave doubts about the Copernican theory of our solar system. Now it is clear that especially in the lying-in room nothing should under any circumstances be permitted which may disturb the confidence of the patient, the family, or of the nurse, in the competency and skill of the physician. And yet I have had to bear to be informed by the nurse in the presence of the patient that in the lying-in hospital where she had her training the vaginal douche is invariably used in every case, and that Dr. A. and Dr. B.—respected members of the obstetrical society,—for whom she had frequently nursed, always expect her to use it as a matter of course, and without being directed to do so. She has heard of doctors who do not approve of it, but cannot remember their names.

Seriously, then, I find a threefold objection to the use of the vaginal douche in normal childbed. First, it is useless; second, it is hurtful; third, it is dangerous.

(1) Uselessness. In this part of my subject I find myself forestalled by two writers in a recent number of the *New York Medical Journal*, and I shall not hesitate to quote from these papers. The first is theoretical, and is entitled "Normal parturition always physiological," by Dr. Ernest Palmer, of Brooklyn, N. Y. The advanced school of obstetricians hold that gestation and parturition are "more or less pathological conditions." This Dr. Palmer denies. He takes from Leishman's Midwifery a description of the vagina and cervix during labor, and describes the nature and use of the profuse mucous flow at that time. He says: "Upon the quantity of these secretions the ease of the labor undoubtedly depends in no small degree." Now we are directed by the antiseptic school of midwifery to wash away these secretions upon the presumption that they furnish a nidus for, or may prove a source of, septic infection. "In other words," says Dr. Palmer, "removing an important physiological factor from a normal delivery to prevent a possible pathological complication." After the labor the antiseptic midwife or physician continues to act upon a similar fallacy. "Prophylactic vaginal douching and medication with iodoform is at once resorted to," to prevent absorption of some

<sup>1</sup> Read before the South Boston District Medical Society, Section of Obstetrics and Gynecology, December 17, 1884.

supposed poison or infectious matter through the lacerated mucous membrane of the vagina or cervix, or by the presumed denuded tissues of the uterine cavity itself. Absorption of what poison or infectious matter? To wit, the lochia, consisting of a thin bloody fluid weeping from the site of the detached placenta, combined with products of a retrograde metamorphosis of tissue entirely physiological in character. He shows, moreover, that "the supposed denuded muscular tissue of the uterus is a condition which has no existence." Dr. Palmer says: "Uncomplicated labor is a purely physiological act, for which ample preparation has been made in the system to provide for the increased demand made on it, and to guard against all the ordinary incidents pertaining to that function." He enters a firm protest against the antiseptic douche as being established on misconceived theories of pathology and in direct violation of the physiological laws of reproduction, being both unnatural and irrational. Now, if Dr. Palmer's view is the correct one, the practice of douching the vagina in childbed is no more defensible than would be the practice of giving antiseptic clysters to prevent infection from fecal matter; and it is well known that septicæmia from wounds or fissures of the anus is one of the very rarest of accidents.

Moreover, there is high authority for the opinion that the lochia depend upon a condition in every respect analogous to what occurs in menstruation, namely, "an exfoliative shedding of the mucous membrane of the uterus." Leishman says that at no time is the normal discharge of the lochia "in any way analogous to the suppurative which accompanies the reparative process of a healing stump." Dr. Tyler Smith, as quoted by Dr. Palmer, says that the analogy is perfect between the menstrual fluid and the lochia. I think no one of my hearers would think it wise to introduce the practice of douching the vagina during menstruation in every female. Yet according to Dr. Palmer this about what we do when we are washing out the vagina in a healthy parturient woman.

Per contra, in an address lately delivered by Dr. T. Gaillard Thomas before the New York State Medical Association, he says: "Although the obstetricians of to-day are not prepared to make aseptic midwifery the rule, it is highly probable that in the near future this position will be accepted." He compares it to the antiseptic surgery of amputations and of laparotomy. Such views from one who stands as Dr. Thomas does, in my opinion, *facile princeps* among American gynecologists, cannot fail to make a humble pupil pause and look warily over the ground before proceeding farther. I would ask his pardon for daring to present an adverse view of this question. It should be remembered, however, in excuse of my temerity that Dr. Thomas speaks from the standpoint of the gynecologist and not from that of an obstetrician. We believe that all diseases are only so many modifications of the healthy condition. But is it true that the parturient state is such a variation from health as we ordinarily mean in speaking of disease? Now this question is altogether too profound and too intricate to be slightly treated in a twenty-minute paper. Indeed, it is doubtful if any line can

be drawn showing when in the course of imperceptible gradation health ends and disease begins. But there is an abstract position which we may be permitted to occupy upon this matter. Is it likely that of all organic functions that upon which the continuance of species depends, and which is common to all animal life, should be the one which acts only under conditions tending to decay and death; that is to say, under conditions of disease? Is it not, on the other hand, probable, *a priori*, that this function, in every one of its separate parts, is especially guarded against those accidents which produce disease? That nature should seek to continue, and yet use means that by reason of defect may hinder or disturb the continuance of a race or species, is simply incredible. Nor can it be argued that, in the case of mankind, civilization, or abuse of function, or an effort of nature to prevent overproduction, or other supposable cause, is operating to confuse or pervert the order of things. I think, then, we assume that there can be no real analogy between normal parturition and what takes place after amputations or laparotomies. And if there be no analogy between these conditions, what grounds have we to act upon similar theories or to employ similar methods in their treatment? So much for theories.

But all such arguments are idle if it can be shown that in clinical practice the use of the vaginal douche will cut short or prevent the spread of puerperal fever, peritonitis, or septicæmia in hospitals. And here I find one of the strongest arguments to prove the uselessness of the practice under consideration. It is, I believe, a fact that the employment of the vaginal douche does not prevent the occurrence of the diseases in question in those institutions where it is in constant use. But does it prevent the spread of infectious diseases? To prove this we should have cases treated side by side at the same time and place by the two methods. Satisfactory evidence of this kind is not at hand. But I will ask you, gentlemen, to say if any of you would have the slightest confidence in the vaginal douche, however thoroughly used, to stamp out puerperal fever, should it occur in a hospital under your control. And if this method is useless in lying-in wards, of what possible good can it be in private practice, where the mortality from child-bed diseases is four or five times less, according to the statistics of Winckel?

And in this connection I will quote from Dr. Charles Jewett, of Brooklyn, N. Y., Professor of Obstetrics and Diseases of Children in the Long Island College Hospital, whose paper is also in the *New York Medical Journal* for November, 1881. He says that his recent experience has led him to abandon prophylactic injections as a routine practice in the puerperal period. In 1883 two parallel series of hospital cases were treated side by side by his direction, one with and the other without the douche. There were twenty-nine cases in all, sixteen douched, thirteen non-douched. One to 1000 bichloride solution was the principal disinfectant employed, three to five per cent. carbolic being used in a small proportion of the cases. These injections were administered by competent trained nurses, and were repeated at least twice a day during the post-

partum week. The mortality was less in the non-douched than in the douched. This is not much, but as far as it goes it proves nothing in favor of the douche. For a time also all wounds or injuries occurring during labor were carefully treated with antiseptics, but even this method was at last abandoned. Dr. Jewett's confidence in the value of the practice being shaken by his experience. He says it became clear to him that this treatment was of no effect in preventing puerperal fever. So much for the clinic.

Pathology gives no support to the use of the vaginal douche. On reading the records of autopsies in cases of puerperal peritonitis I discover the fact that in the greater number of cases the uterine cavity and the vagina are found to be in a healthy condition. Can it, then, be maintained that any importance attaches to antiseptic douching of these parts? In a case of acute peritonitis in a young child, lately reported in the *Medical and Surgical Journal*, the closed cavity of the peritoneum contained an odorless fluid which was filled with *micrococci*, according to the evidence of Dr. H. O. Marcy, who examined it carefully under the microscope. Is it not, indeed, admitted by the best authorities that the microorganisms which are recognized as the ferments which give origin to purulent infection, puerperal fever, and septicaemia, in many cases find their entrance into the body of the parturient woman by other avenues than the generative tract? I will only refer to the valuable papers of Dr. Kinkead, of Dublin, in the July and August numbers of the *Obstetrical Journal* of 1884 in support of this opinion. And if it be so, I ask again of what use is the vaginal douche?

There is yet another proof of uselessness in the "method," to which I shall refer when speaking of hurtfulness.

(2) Hurtfulness. Meigs says in his "Midwifery": "There is in natural labor no element of disease," and therefore, the old writers have said nothing truer nor wiser than that "a meddling midwifery is bad." The method of douching the vagina substitutes an artificial for a natural problem. It is meddling, and therefore it may be hurtful, midwifery.

If septicaemia be at times autogenous, which I by no means deny, I should like to ask any practical observer if the frequent washing with water (carbolized or not), of rents, or tears, or abrasions, of mucous membrane does not delay and interfere with the process of union of such parts. That is certainly my own experience. If this is so, this douching is hurtful by prolonging the period of exposure to autogenous infection. Again, it is hurtful by causing pain and annoyance, more or less in every woman, but in nervous and irritable subjects enough to forbid its frequent use. This, again, is "meddling midwifery."

But the hurtfulness upon which I would chiefly insist is of a much graver character, and inheres in the method itself.

It cannot escape notice that great importance attaches to giving the management of the douche into the hands only of trained, competent, and careful nurses. Now Dr. Thomas, in the address already referred to, speaking of antiseptic midwifery, says:

"That it can do no harm is quite evident." It is to be regretted that the doctors themselves should not know all that the nurses seem to know of the occasional experience in giving these douches. Are many physicians aware that at times the water injected does not flow out in a steady stream, but is suddenly and violently ejected in jets? That pain and spasm of the uterus occur? More than that, sometimes only a part of the water escapes at the moment, but, after perhaps an hour or two, there is a sudden and violent gush. Who can doubt that in these cases the water has entered the uterine cavity, of course carrying with it effete and decomposing matter found in the vagina, and which has been already expelled from the uterus? I ask what is to prevent the entrance of water when the os uteri is patulous?

And what harm can be done by an unskilful or careless nurse using the douche incautiously? The tube may enter the uterus, air may be injected, or too much force may be used. Of the first two I shall say little, as I believe them to be avoidable accidents; but the last is, I think, — to use Carlyle's phrase, — humanly impossible to avoid, except on conditions which render the douche futile as a means of detaching or removing clots and *débris* from the relaxed and rugous vagina. The doing this work with any thoroughness requires that some force be given to the current of water. And here I see another proof of the uselessness of the method, since a mere trickle or feeble stream can accomplish nothing, unless almost indefinitely kept up. And what is it we require of a skilled nurse? Let me suppose a case. A faithful woman has given the douche, say two to four times daily for a week; she has been somewhat severely tried by want of sleep and care of an exacting patient and infant night and day; at last, on the seventh day, when attempting to use the syringe, she finds that there is some obstacle in the way, the tube catches in a fold of mucous membrane, perhaps is entangled in a clot or shred of decidua, and she gives the bulb an impatient squeeze. When under such conditions as I have here described any grave accident occurs it seems to me cowardly and idle to lay the blame upon the nurse. It should be put where it properly belongs, namely, upon the practice itself.

It is unnecessary to point out the harm that may result from thus injecting the uterus from the vagina. It is an unhappy accident. And this brings me to the

(3) Danger. I will cite an actual case, giving no names. A young woman in full and vigorous health, a fond and devoted wife, a mother for the first time, a proud and happy husband and father, — this was the family. On the morning of the seventh day after delivery everything was going on perfectly well. The doctor considered the case finished. The wife had parted from her husband after breakfast, and he had gone in town to business, at her request, to stay until night. At 10 A. M. she sent him a telegram telling him not to come back at noon, she felt so perfectly well. This was the situation. Shortly after this telegram the nurse, who had, by direction of the physician, given the vaginal douche twice at least daily since confinement, prepared her syringe as usual. While the injection was

flowing into the vagina the patient suddenly uttered a shriek, "Oh! what pain! What have you done to me? I shall die! I shall die!" turned pale as death, gasped as if suffocated, her lips became livid, and she writhed in agony. This is the picture as given to me soon after by one of the family. The doctor and the husband were sent for, but she sank into unconsciousness, became convulsed, and was dead before evening.

I have it from our lamented pathologist, Dr. Calvin Ellis, who was present at the autopsy, that air was found in the veins and heart.

There is no member of that family, and none of those who saw the case, who, as I believe, entertains a doubt that the use of the douche was the cause of death; the *antiseptic douche*, of which Dr. Thomas says, "That it can do no harm is quite evident." The nurse, I understand, admits that she used more force than she intended to use. The doctor, a woman, blames the nurse. This is ungenerous and irrational. The danger inheres in the practice itself.

Since I began the preparation of this paper I have heard of a case in the practice of a neighboring physician, similar in many of its features to that just related, where, however, the final result was not reached until the fortieth day, the patient dying of septicemia. The doctor, who did not see her at the time, says he does not know that the douche was the cause of death. Cases are known of collapse and shock following the use of the douche.

It is doubtless true that death is exceedingly rare from this practice. But we do not hesitate to reject chloroform as an anæsthetic on no better grounds than this. So much for the danger.

I would thus sum up my objections to the antiseptic douche in midwifery. It is artificial; it is meddlesome; it is of doubtful utility, and it may be hurtful and even fatal.

#### A CASE OF CANCER OF THE HEAD OF THE PANCREAS.<sup>1</sup>

BY T. M. ROTCH, M.D.

THE following case presents certain prominent points of interest, in that the physical signs from the beginning to the termination of the disease were entirely negative, although the rational signs were so distinctive that it was not difficult to locate almost the exact spot where physical evidence ought and every day was expected to be found; of interest, also, in regard to the diagnosis, from the somewhat striking resemblance to those prolonged cases of gall-stone reported by Murchison, the chief symptoms, from the beginning of the case, evidently being caused mechanically, and the uncertainty as to whether the compression of the bile-ducts was from within or without, existing throughout the whole course of the disease. The result of investigation at the postmortem proved that it would have been impossible to detect anything abnormal on physical examination during life. The condition of the kidney was also of marked interest.

Mr. L., bank president, fifty-seven years of age, married, and with a family history free from hereditary

taint, consulted me in the summer of 1884 regarding attacks of abdominal pain, irregular in character and in time, and coming without reference to eating or drinking. The patient gave a history of confirmed dyspepsia extending over a period of many years, but otherwise he had never been sick, and had considered himself unusually well and strong; his life was one of extreme method and regularity, attending to his business in the morning with great nicety of detail, regularly taking his walk in the afternoon, having his meals punctually and without hurry, never eating or drinking to excess, and never using tobacco. When seen in August, 1884, the complaint was chiefly of his dyspeptic symptoms having grown worse, the abdominal pain at times being so severe, especially at night, as to keep him from sleeping; but it appeared to be much relieved by eructations and rectal discharges of gas, and could not be especially located, as it changed to all parts of the abdomen, though at times he described a new pain separate from that which he had always had, and apparently situated in the right hypochondrium and extending through to the back. He had not lost in weight; the bowels had always been inclined to constipation but were now fairly regular, and the appetite was good. Examination revealed nothing abnormal; the abdominal walls were not only distended with gas but contained considerable fat; the dullness of the liver and spleen was normal. The skin had for many years been of a grayish color, but this was considered by his family to be its normal condition, and varied in its intensity according to the presence or absence of his so-called "bilious attacks."

The patient when next seen, on September 21st, was in about the same condition, and did not consider himself a sick man; but as his business was monotonous and he seemed somewhat depressed, he was advised to take a trip to the White Mountains, which he did, and he did not again come under observation until his return to Boston, October 13th. He then reported that he had not been so well and had been troubled by continual distension from gas amounting to pain; also that the bowels had been much constipated, that he was easily fatigued, did not sleep well, and suffered somewhat more from the pain in the hypochondrium and back, temporary relief, however, being obtained by riding on horse-back and by eructations of gas; he had lost six or eight pounds in the last three weeks. A milk diet with lime-water, and, later, milk digested with ext. pancreatis, failed to give any relief to his digestive troubles, and on the 16th he had a severe attack of abdominal "distress," as he termed it. On October 17th he had a large natural defecation; on the 23d he went to the bank in the morning, but returned much exhausted. An examination of the urine on this day showed it to be normal; the pulse was 90 and the temperature 97.4; from this time the bowels moved every day, usually with the aid of enemata; the pain increased so that the continual use of morphia was required, and the patient did not again leave his room. On October 24th the patient was seen by Dr. Minot in consultation, when a physical examination of the abdomen was made with a negative result, there not even being any tenderness. It was now found that he could take

<sup>1</sup> Read before the Boston Society for Medical Improvement, February 9, 1885.

meat, simple puddings, and baked apples with less distress than was occasioned by liquid diet; he was at this time evidently losing in weight and strength, the latter, however, apparently arising from the exhaustion caused by the pain and the former by the small amount of food taken.

The abdominal walls were fat and there was no tenderness, resistance, or dullness anywhere.

October 27th. The urine was noticed to be dark colored, lessened in amount, and on examination to have a specific gravity 1020, and to contain bile. The pain was much more severe and there was slight nausea, and scarcely any appetite.

October 29th. Jaundice of the skin and conjunctive appeared.

November 1st. The urine was examined by Dr. Hills, with the following result: Color high with greenish tinge. Reaction acid. Specific gravity 1012. Amount of sediment slight. Urea diminished. Uric acid diminished. Earthy phosphates diminished. Alkaline phosphates normal. Albumen faint trace. Sugar absent. Bile pigments present. Fine renal epithelium cells. An occasional hyaline and granular cast. Casts all of small size and having one, two, or three renal epithelium cells adherent.

November 2d. The patient complained of deep-seated pain in the calf of his left leg, but nothing was found on examination but slight tenderness.

November 3d. The stools became clay-colored, and from this time progressively lost the coloring matter of the bile and were very large in amount, in fact unnaturally so, considering the very small amount of nourishment that was taken. No fat was ever noticed in the dejections or anything abnormal beyond the color varying from gray to white, and once the dejection was flattened and coiled like a long piece of ribbon. Every dejection was carefully examined through a sieve for abnormal constituents, especially gall-stones. The jaundice gradually became more marked and by November 7th was quite deep in color. On this day Dr. Hills again examined the urine with the following result: Color high, yellow foam. Reaction acid. Specific gravity 1018. Amount of sediment slight. Chlorides normal. Earthy phosphates normal. Alkaline phosphates normal. Urophacin increased. Indican normal. Albumen a trace. Bile pigments present. Sediment, renal epithelium, hyaline, and fine granular casts, some of which had one or two renal epithelium cells adherent. An occasional blood globule. Renal epithelium and casts somewhat more numerous than on November 1st. Amount of urine in twenty-four hours, 965 cc. Amount of urea in twenty-four hours, 23.1 grammes.

November 15th. The patient vomited once in the night and this occurred at first with intervals of several days and later became more frequent until his death. There was nothing especial found in the vomitus excepting that once or twice there were appearances suspiciously like the coffee-ground vomit (no microscopic examination was however made).

At this time the patient began to refuse to take solid food and was nourished with milk, beef-tea, and brandy.

November 21st. Pulse 90. Temperature 98. Pain has continued. There was decided loss in weight and

strength, with inability to walk without assistance, and the daily amount of urine was diminished to 649 cc. Several times there was a progressive increase or decrease in the urine at the rate of one or two hundred cc. in the twenty-four hours; thus on November 2d it was 725 cc., and it slowly rose in quantity until by November 11th it was 1,500 cc.; it then decreased and was found by November 15th to be 649 cc.

November 25th. Dr. Hodges examined the case in consultation with me, with a negative result, excepting that he thought he felt an ill-defined feeling of resistance to the right and just above the umbilicus.

The painful spot in the left calf disappeared in about a week, but on December 13th the tenderness appeared in the right calf and the whole right leg and foot became swollen and continued so until death.

About the middle of November a congested condition apparently of the capillaries of the skin forming little circles and half-circles was noticed on the back in the region of the right kidney, and this gradually extended up and down the back and around the right side to the front of the abdomen, covering the right hypochondriac region; the color was darkish red, mottled, and disappeared on pressure; it closely resembled post-mortem lividity and was still noticeable at the time of the autopsy, though much less distinct than during life.

From this time the patient rapidly became emaciated and weak; the mind remained clear and the only complaint was of pain and tenderness in the right hypochondrium. He became unconscious on the morning of December 17th and died quietly in a few hours.

*Autopsy*, by Dr. W. F. Whitney, six hours post-mortem. Slight rigor mortis. Marked yellowish-brown color of entire body. On the back were several irregular dark spots fading into the post-mortem lividity. Right leg considerably enlarged.

Head not opened. Pleural cavities—In the left a few hundred cc. of fluid. Pericardium contained about thirty cc. of deep yellow-colored fluid. Heart normal in size. Muscular substance slightly yellowish in color and somewhat opaque. Microscope showed the presence of a large number of granules in the cells, which cleared up on the addition of acetic acid; there were also pigment granules about the ends of the nuclei. The blood coagulated in loose dark clots. Lungs—The left lung was slightly adherent by thin bands at the apex. It did not collapse entirely upon removal. The lower lobe was dark red and in it were two nodules the size of a pea, which on section were soft and of a medullary aspect. From the surface a plentiful bloody and frothy fluid could be squeezed. In the right lung the appearances were similar excepting that the nodules were warty. Spleen—Large, capsule smooth, dark red in color; on section follicles indistinct. Kidney—Long and rather narrow. Cortex—Slightly opaque and whole organ of a yellowish color. Capsule not adherent. Spots of hemorrhagic extravasation beneath the mucous membrane of the pelvis, but no signs of inflammation. Microscope showed an occasional fatty tubule with general granular degeneration.

Connective tissue but little increased. Liver—Not greatly increased in size. Anterior edge of right lobe thin and projected below edge of ribs but very little. The organ was everywhere studded with reddish-white medullary-looking nodules having a slightly depressed centre. These varied in size from a pin's head to a walnut. The gall-bladder was distended by dark liquid bile and the cystic and hepatic ducts were greatly distended. The common duct was involved in a large reddish-white opaque mass, the size of a small orange, traversed by bands of connective tissue forming a growth in the head of the pancreas. The tail of the pancreas was normal. By using great force a little bile could be squeezed out of the papilla, but none had apparently escaped of itself.

The new growth had just involved the coats of the intestine at the place of opening of the common and pancreatic ducts, but had not quite broken through.

No effusion was found in the abdominal cavity or adhesions beyond those of the liver with the diaphragm.

**Diagnosis.** Cancer of the pancreas involving the common duct and causing obstruction to the flow of bile. Secondary cancer of liver and lungs. General icterus. Edema of lungs. Parenchymatous degeneration of kidneys. Parenchymatous degeneration of heart.

## Reports of Societies.

### PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M.D., SECRETARY.

FEBRUARY 9, 1885. The President, DR. F. W. DRAPER, in the chair.

#### CANCER OF THE HEAD OF THE PANCREAS.—ELIMINATION OF BILE BY THE KIDNEY.<sup>1</sup>

DR. T. M. ROTCH read the report of the case.

DR. W. B. HILLS said that where bile is continuously reabsorbed it becomes separated by the urine, and that active hyperemia of the kidney may be caused by the presence of bile pigment. He referred briefly to another case of obstruction by cancer, this time in the mesenteric glands, in which he had examined the urine daily for between one and two months. It was at first unchanged, as in Dr. Rotch's case. In a few days bile pigments were detected, and after that hyaline casts. Albumen was still later in making its appearance, bile pigment continuing permanently. There were at last granular and epithelial casts. In these cases where the urine is dark, it is hard to detect small quantities of albumen by the aid of nitric acid; and other tests, as, for instance, heat, are better. Bile-stained epithelium may be seen by the microscope before bile is discovered chemically.

In the case of which he had spoken, the amount of urine had, as in Dr. Rotch's case, risen progressively and then diminished. It should be kept in mind that a man in bed will pass less urine than one who is about, and that the amount will be

changed by the food and liquid taken; still, in the case in question, the amount of urine had decreased as the bile pigments had lessened.

DR. W. F. WHITNEY said that in regard to the frequency of occurrence of primary cancer of the pancreas, it was found by Klebs from an analysis of five hundred cases that it occurred in about two per cent. Among ninety-five hundred deaths reported by the Board of Health of the City of Boston for the last year there were three hundred from cancer. On that basis there should have been five or six cases of cancer of the pancreas, and from the number of cases which have been shown at the Harvard Medical School during the past few years, these figures would be approximately correct. So that the disease is certainly to be classed among the rarer ones.

As to the length of time it had existed, there is no possible way of determining from the autopsy. This must be inferred entirely from the clinical history and from the analogy of cases which have their seat on, or just beneath, the surface. In this case the disease had probably existed some time before the disturbance caused by its growth gave rise to urgent symptoms.

In its nature and seat it was not remarkable, involving as it did the head of the organ and pressing upon the common duct; but at the same time having its own uncompressed. Although rich in cells in parts, in others it presented the dense contracted interstitial tissue with scattered nests of cells which would characterize it as a "scirrhous," and this is the most commonly recorded form.

The study of the microscopic preparation showed very plainly the passage from the normal glandular arrangement of the epithelium to the atypical alveolar structure of the more medullary portions. In the midst of this latter were still to be seen well-preserved bits of the ducts, showing that the growth started from the parenchyma of the organ.

The secondary nodules in the liver were interesting from their origin in the periphery of the acini and their extension between the rows of liver cells.

#### EPIDEMIC CHOLERA.—ITS PATHOGENESIS AND ETIOLOGY.—HISTORY OF THE LAST EPIDEMIC.

DR. GEORGE B. SHATTUCK opened the discussion by the following remarks on the history of the last epidemic in Europe, with certain conclusions.

MR. PRESIDENT AND GENTLEMEN.—On reflecting upon your request that I open the subject announced for discussion this evening by a review of the course of cholera epidemics and the lessons they teach, it seemed to me that the limited amount of your time which it would be proper for me to appropriate could be most profitably occupied by a short statement of the most prominent features of the last outbreak in Europe. The former epidemics are familiar to most of you, or, if not, various accounts of them are easily accessible.

The details of the last epidemic have been, as far as I know, nowhere brought together as yet. After mentioning the most striking points of this outbreak, I shall venture to draw such deductions from these and other observations as seem to me calcu-

<sup>1</sup> See page 175.

lated to suggest, or provoke, the discussion which is desired.

The first death from the recent epidemic at Toulon occurred on June 14th. The port had been in constant communication with Cochín China and Tonquin, where cholera is almost an endemic, and, in fact, an unusually severe outbreak had been prevailing at Saigon through the spring months. Three French transports had recently returned from Cochín China; they are said to have brought clean bills of health, but French transports have been known to pass through the Suez Canal with clean bills when cholera existed on board. The clothes of sailors who had died from cholera were ordered to be burned before sailing for home, but after the arrival of these transports at Toulon an auction sale of the clothes and personal effects of the other sailors who died in Tonquin, but not from cholera, was held by order of the marine authorities. This is the most probable explanation of the outbreak at Toulon. Old soiled clothing—not baled rags—is one of the most common carriers of the cholera poison. The first case occurred on board a vessel which had been in port fifteen months.

The sanitary condition of Toulon was, and always is, deplorable. There are no sewers; refuse and excrement of all kinds are thrown into the gutters, and are carried into the tideless port. Typhoid fever, which resembles cholera quite closely in its habitat and locomotion, thrives extraordinarily in Toulon. Dr. Lippertz, who accompanied Koch to Toulon, is responsible for the following suggestive statement: "Close to the harbor was a public market where fruit, vegetables, snails, and other Southern delicacies used to be sold. By the side of the market, gutter-water of questionable clearness flowed. The market people, however, considered the water good enough not only for cleaning their stalls but also for refreshing their thirsty goods." Here is another instance exemplifying a common way by which the cholera poison is disseminated.

From Toulon cholera was carried to Marseilles where the first case appeared on June 25th, and from there it spread to Arles and various smaller towns. By the middle of September seventeen departments had been invaded in succession, and 5,000 deaths, representing 10 to 12,000 cases, were reported to have occurred; the total mortality from all causes in the whole of France during the same period being about 200,000.

At the end of July cholera appeared in Italy, being introduced by Italian workmen fleeing from Marseilles. Notwithstanding stringent quarantine proclamations and annoying restrictions it entered at Leghorn by water, and crossed the Alps and spread through the northern provinces. The disease made its appearance at Rome several times, but on each occasion was held in check and did not spread. The water-supply and drainage at Rome are said to be unusually good, and the authorities were on the alert to isolate cases as they occurred.

Rumors began to prevail very early in August that cholera had reached Naples, but it was not till August 27th that two deaths were officially admitted to have occurred from the disease. The water-supply is notoriously poor and insufficient and the drainage wretched. In the quarter of the

Porto, where the cholera was most virulent, all the cisterns and wells were found upon investigation by the Syndic to be impure. The outbreak at Naples was the most severe of any during the late European epidemic. According to the medical returns the number attacked was 11,467, and the number of deaths 6,852, but there is every reason to suppose these numbers are considerably below the truth. The White Cross Society nursed 5,492 cholera patients, of whom 3,260 died. The city now proposes to spend 100,000,000 francs in sanitary improvements.

The total number of cases that were known to have occurred throughout Italy up to October 20th was 21,519, of which 11,563 terminated fatally; the population of the kingdom being between twenty-nine and thirty millions. After Naples, Spezzia and Genoa suffered the most.

Spain also issued stringent quarantine proclamations and regulations, but was invaded by cholera even earlier than Italy. Although the disease appeared at various different points, at each of which a comparatively limited number of victims died, and lingered through the summer, there was nothing like a severe epidemic in any of the large towns. I have seen no explanation to account for its different behavior in Italy and Spain.

When cholera had nearly run its course in the southern departments of France it broke out at several points in the northern departments. At Yport, a small fishing village near Havre, it was introduced by two sailors who reached the village September 28th. From M. Gibert, in the *Revue Scientifique*, as translated in *Science*, we get the following interesting and instructive details of this miniature epidemic:—

One of the sailors had an attack of cholera at Cette; and on the day after his arrival at Yport he soaked his soiled clothing, and hung it out to dry in front of his house, allowing the dirty water to run along the street.

From this nidus the disease started, and there occurred forty-two cases with eighteen deaths. Gibert's conclusions—justifiable, apparently, from the account which he gives—were as follows:—

- (1) That cholera was brought to Yport.
- (2) That it was brought by insufficiently disinfected clothing, soiled by cholera dejecta.
- (3) That, after this clothing was washed, it became the agent of severe and rapid contamination.
- (4) That the cholera was propagated, by means of contagion, from house to house, without its being possible to attribute a single case to the transportation of the specific germ by the air.
- (5) That the sanitary measures taken, although incomplete, inasmuch as it was not possible to separate the sick from the well, were sufficient to stamp out the epidemic.
- (6) That the complete destruction of the cholera dejecta, and the disinfection or destruction of all effects soiled by them, seem to be sufficient to stamp out an epidemic of the disease, when it has not attained too great proportions.
- (7) That contagion by the air (the common acceptance of the term) appears to be an error; for at Yport three nuns and three physicians, or

students in medicine, lived for a month under the most favorable conditions for taking the disease by this channel. They all escaped, with no further precautions than taking their meals at a distance from the cholera patients, and avoiding the handling of moist and soiled clothing.

(8) The question of water has no bearing in this case, for the very good reason that the Yportais never drink any.

A limited epidemic was started at Nantes October 25th.

At Paris the first case entered the hospitals November 4th. From this time till the end of November, when there were several days of sharp frost and the disease disappeared, there were 916 deaths. The total number of cases was not accurately known, but as the deaths were not much short of fifty per cent., there were probably 1,600 or 1,700 cases. The number of cases received at the hospitals was 1,002 and the number of deaths 573, a mortality of fifty-seven per cent. The disease was confined to the poorest quarters of the city. No visitors were attacked. The sanitation of the quarters visited and the condition of those attacked warranted a high death-rate.

In 1865 cholera broke out in Marseilles in June, and it reached Paris September 18th, thirty-six departments becoming infected. By the end of the year it had caused 6,441 deaths in Paris. The disease continued through the winter; in July it again became epidemic and continued active for four months, when it died out.

In 1873 cholera reached Paris from the south, September 5th, and continued active until December, when it disappeared, and did not reappear the following summer.

Before 1865 Paris and France had always been reached from England, and England from the Baltic ports of Russia and Germany.

Every time that cholera has obtained an extended foothold in Europe this country has been visited sooner or later. The United States have been invaded twice through Canada, twice through New Orleans, twice through New York; on one of the last occasions the poison being carried to points at the West in clothing which had passed quarantine. Cholera has been held in check by quarantine at New York, but the season of the year was favorable, and the poison entered at other points.

To sum up, allow me to state in brief the following conclusions:—

(1) Infected clothing, especially if damp, and contaminated water are fertile breeders and common carriers of cholera poison; witness Toulon, Naples, Yport.

(2) Vigilance, seclusion of sick, and sanitary precautions are efficient agents in excluding or destroying the poison; witness Rome and Yport.

(3) Cold is a useful adjunct to the above; witness Paris.

(4) Quarantine and cordons may delay the entrance of cholera, but will not practically exclude it, even from a country as favorably situated as the United States.

(5) The poison is absorbed through the alimentary canal, not by the lungs or skin, and contagion in

the strict sense of the word is but little more to be feared than with typhoid fever.

(6) There is nothing to show that therapeutics have made any progress in twenty-five years in opposing the disease, and the mortality as indicated by the late European epidemics remains about the same, forty to fifty per cent.

Dr. R. H. Fitz read a paper on the pathology of the disease.<sup>1</sup>

Dr. H. C. Eixst showed some comma-bacilli received from Koch two months ago. He said that the mouth bacillus of Lewis had been recognized for some time. Its microscopic appearance is so like that of the cholera bacillus that it takes a practised eye to distinguish between them, and this is the more true because it has been impossible to find different stains for the two bacilli. When cultivated in test-tubes, however, they are entirely unlike. The cholera bacilli sink into the gelatine in which they are growing, leaving a thread-like line of liquefaction from the surface to the bacilli at the bottom. The mouth bacilli on the other hand liquefy almost the entire surface of the gelatine, making a large liquefied cylinder. All this is new. The subject is so new that our knowledge of it grows materially in six months, and gentlemen are mistaken if they suppose that new means of distinction are brought forward because observers are driven into a corner. It is but the natural growth of a new subject.

Dr. W. W. GANNETT said that the impression one got from reading the recent literature in regard to the relation of the comma-bacillus to cholera was that the medical world was divided into those who believed that it was the cause of cholera, and those who denied that it stood in this relation. For his part he believed in neither of these extremes, but preferred a middle course, namely, a suspension of judgment until more light had been thrown upon the subject by further investigation. The necessary factors to establish the causative relation of a microorganism to a disease were mentioned; the constant presence of an organism presenting definite characteristics; the isolation and cultivation of such organisms outside the body; finally the production of the disease by inoculation in animals. Of course, failure to produce a like disease in animals would not of necessity throw out the possibility of the microorganism being the cause of the disease, as there may be a want of susceptibility on the part of the animals inoculated. Dr. Gannett considered the experiments thus far performed on animals by feeding with, or injection of, the comma-bacillus unsatisfactory, and thought that better results might be looked for in the experiments on man. Klein had swallowed the comma-bacilli without ill effect. Koch had criticised the value of this experiment by stating that the culture used may not have been a pure one, and that there may have been an insusceptibility on the part of Klein. Such a criticism is perfectly just for an isolated case, but Dr. Gannett doubted whether a similar want of positive result would count for so little provided Pettenkofer's offer of swallowing one of Koch's own cultures and getting twenty others to do the same were followed out. It is difficult to suppose a want

<sup>1</sup> See page 169.

of susceptibility on the part of twenty men taken at random, considering how many are attacked during an epidemic of cholera. Dr. Gannett considered experiments on men by swallowing the comma-bacilli as of value, because it is through the mouth that Koch and most others suppose that the poison of cholera gains entrance.

Dr. J. C. WHITE did not think that negative evidence of this kind is valuable. It shows that the experimenter does not know how to inoculate the particular bacilli. It does not show that it cannot be done. Favus is known to be contagious for instance. Hundreds of attempts to inoculate it failed, but after the proper method had been discovered, then there were no more failures. For two years attempts were made to inoculate leprosy without success, but it has since been done. With a bacillus so recently discovered as that of cholera he should think a failure to inoculate of no account.

Dr. FITZ said while Pettenkofer's experiment, performed with a cultivation satisfactory to Koch, would go far toward proving his point, and that Pettenkofer may have made the statement, yet that it did not appear on the official record of the meeting where it is supposed to have been made. An experiment of the kind is of little value unless well conducted. Klein's may have failed from the bacilli being digested in an acid stomach. There have been no careful experiments as yet in inoculating in this way.

Dr. GANNETT said that shortly after the meeting in Berlin the *Fortschrit der Medizin*, edited by Friedländer, had ridiculed Pettenkofer's offer as bravado. In the next number, however, Friedländer had made a formal apology, and stated that Pettenkofer had made his offer, both for himself and his companions. Dr. Gannett could but feel that the offer was not bravado. As to the advisability of the attempt, he himself would not make it, nor would he recommend it.

Dr. FITZ said that after Friedländer's explanation, which he had not seen, there could be nothing more to say about the offer. It does not appear, however, that the experiment has been made.

Dr. ERNST said that he thought one experiment or twenty would be absurd. We do not know how many millions are exposed during an epidemic without contracting disease.

Dr. GANNETT reminded the last speaker that the method of inoculation is not supposed to be by the air, but by the mouth, which the more cleanly people defend by their cleanliness, and that it is by the mouth that Pettenkofer proposes to perform his experiment.

#### STUFFOLK DISTRICT MEDICAL SOCIETY.

##### OBSTETRIC AND GYNECOLOGICAL SECTION.

ROBERT B. DIXON, M.D., SECRETARY.

DECEMBER 17, 1884. The meeting was called to order at eight o'clock. Dr. James R. Chadwick in the chair, fifty-six members being present. Dr. Z. B. Adams, of Frammingham, read by invitation a paper entitled—

#### THE USE OF THE VAGINAL DOUCHE IN NORMAL CHILD-BED.<sup>1</sup>

Dr. RICHARDSON said that he taught that the vaginal douche should be used. He has never had any difficulty in using or bad results following the douche.

Dr. MARCY stated that he concurred with the reader regarding the limitations given to the use of the douche. He considered parturition as a physiological process, and in normal labors nothing was required beyond strict cleanliness—surgically speaking, an aseptic condition. This, for many years, he had endeavored to obtain, and for better protection had used in a routine way napkins moistened with a solution of carbolic acid, and changed often. He had also used iodoform considerably. If decomposition occurs within the vagina, then a pathological state ensues and vaginal douches of antiseptic character are requisite. Although the vagina and uterus are excellent incubating chambers for rapid germ reproduction, when infection has taken place, the normal outflowing current is in itself a natural protection from implantation of bacteria, since they are always passively carried in the infected fluids in the direction of the least resistance. This is the probable reason why in normal unassisted labor the uterus and vagina remain aseptic, although marked decomposition has occurred in the secretions about the external organs where atmospheric exposure ensues.

Dr. PINCO remarked that during nearly forty years of obstetric practice he has not used the vaginal douche after normal labor; and freedom from untoward conditions had been almost exceptional in his experience. He had seen nothing of those conditions said to arise from bacilli and micrococci, and he had grave doubts of the malignant character of those germs which had been so fearfully pictured to the world. He should avoid the use of the douche unless it was called for by unhealthy conditions.

Dr. ABBOT expressed his cordial agreement with the reader regarding the use of antiseptic vaginal injections after normal labors. In his experience years ago as a dispensary physician, during two years and a half he had never seen a death from any form of inflammation following labor, even when it had taken place under the most unfavorable hygienic surroundings. The medical profession is almost compelled nowadays in obstetric matters to accept the rules laid down by gentlemen whose experience has been mainly gained in lying-in hospitals, where the patients are placed under very different conditions from those in private practice. He had himself employed vaginal injections, after normal labors, in only a few instances, and of late had not used them at all. It should be remembered that in cases of threatened danger from post-partum septic inflammation the relief obtained had been from *intrauterine*, not *vaginal*, injections. Indeed, so high an authority as Dr. Robert Barnes has said that in all puerperal women the uterus should be washed out once or twice daily for a week after confinement with a solution of carbolic acid—

<sup>1</sup> See page 172.

a recommendation which he felt safe in saying had not met with much favor with the medical profession.

Dr. REYNOLDS said that he regretted the repetition of a statement which he believed to be untrue, that, of necessity and inevitably, the aggregation of women in lying-in hospitals involves a high percentage of death. Nowhere, except in these hospitals, can the thoroughly competent accoucheurs that every community so urgently needs receive adequate training, and in the absence of any such refuge crowds of suffering women are in all populous centres left practically without relief. As a matter of fact, the assertion is not true. The inmates of the Rotunda in Dublin fairly represent the classes most likely to suffer in childbirth. Dr. Macan, in an admirable report just published, shows the total mortality of that hospital for the past year to be only one half of one per cent. We have equally encouraging results from St. Petersburg and from other quarters. Of what value, in offsetting these facts, is a *résumé* of hospital experience for the last fifty years in places of every sort, good, bad, and indifferent? The public, no less than the profession, are entitled to have this proposition flatly denied as often as it is repeated. He heard with amazement the "physiological" argument, as to the impropriety of cleansing a mucous surface. Wash well the vulva, but consider the risk of purifying the vagina. Take care that no brush enter the mouth; though a man may with safety bathe his lips. The reader discourages washing out the uterus, because, in many instances, disease goes on afterward unchecked. This may well be true. Septic infection has often other points of entrance than the lining membrane of the uterus: so that the most faithful cleansing of that cavity must many times do no good. In cases of another variety every threatening symptom promptly subsides under the use of these measures. Not long ago Dr. Matthews Duncan reported an illness where, in spite of watchful and judicious care, an alarming condition was long maintained, to disappear as if by magic when he detached from the fundus with his finger a seemingly insignificant scrap of membrane, not longer than a florin. Dr. Reynolds believes in strict cleanliness after labor as emphatically as he does in preventive management of women about to be confined. It is often impossible to ensure the careful washing out of the vagina, but he rejoices whenever he has the luck to obtain for this duty a capable and intelligent nurse. He has not yet seen either injury or suffering from this practice. Nearly every woman expresses her consciousness of comfort given by it. He never allows himself to direct such washing without forbidding any force in the administration. Instances of abuse of a remedy surely do not form any argument against its proper and legitimate employment.

Dr. J. S. GREENE, of Milton, said he was not a decided partisan on the subject of douches. From his standpoint of a practice in a healthy suburb, and having an inclination not to be meddling, he ordinarily did not use douches after normal labor. He did not hesitate, however, to use them in such cases as presented grounds for suspicions of morbid tendencies. He had not seen harm result from

douches, but had reason to believe that he had seen them serve as valuable aids in securing the safety of patients.

Dr. DOE mentioned two cases occurring in his practice of women who had used douches, quickly followed, in both cases, by intense pain and all the symptoms of prostration. These cases were from the abuse of injections, the nurse having inserted the tube too far. He is now very careful in his instructions to nurses and permits the use of the Fountain syringe only, and the insertion of the tube not more than an inch.

Dr. McCOLLUM stated that he always uses vaginal douches in his obstetric cases. They serve to make the woman more comfortable, and there is not so much likelihood of deleterious matter being absorbed. He has never had any trouble from the use of vaginal douches. He thinks the centre hole at the end of the tube should be abolished.

Dr. RICHARDSON said that he believes in preventing trouble by using injections, and keeping the patient clean. Good results have been obtained in hospitals from the use of douches. There is no potent reason why a douche should not be used after delivery, once or twice per day, even if only to keep the parts clean, the same as the stump of an amputated limb is washed. Those who have spoken against the use of the douche, and, to sustain their theory, have brought forward one or two cases, in which bad results have followed, should remember that an occasional bad result carries with it but little weight, the result being due perhaps to the method in which the douche had been given. The tube attached to the old Davidson syringe was not suitable to be used for vaginal or intrauterine douches. Now the company manufactures a tube without the centre opening at the end. The Fountain syringe is perhaps safer, but the Davidson as now constructed works nicely, satisfactorily washing away deleterious material. The vagina possesses the power of absorption as well as the uterus, and from washing out the former there is no doubt that more or less benefit arises therefrom, for, besides the comfort to the patient, most certainly if any decomposing germs are present the douche must wash them away and, thus far, prevent their absorption. It is his custom to use the douche as a prophylactic measure in private practice as well as in the hospital.

In the Boston Lying-in Hospital douches are given twice daily during the first ten days following confinement, after that once a day. This custom has been kept up for years and no bad results have ever followed the use of the vaginal douche. When it is considered that at the hospital vaginal injections have been given for several years, forming a total of many thousands (a ready calculator can easily see how many), it seems incredible that no accident should have followed their use, like those alluded to by the opponents of antiseptic obstetrics.

Dr. KINGMAN remarked that, in the first clinic of the Prague Hospital, there had been no deaths for one year and four months among fifteen hundred cases. Copious douches are given regularly with a Fountain syringe through a glass tube having a single large opening.

Dr. LOWMAN said that the vagina is subject to

lacerations giving rise to an opportunity for absorption to take place, and douches should be used to wash away any deleterious substances. It has been shown at maternity hospitals that the mortality has been reduced when injections are used. It would seem that it is the duty of the physician to use them. The dangers from douches arise from their misuse.

Dr. BOWDITCH said that he came to the meeting indisposed to believe in the necessity of washing out the vagina after every case of labor, which he considered as a physiological fact, not followed or accompanied by a pathological state, save in exceptional cases. Years ago, when a general practitioner, he had had many cases of midwifery. No douches were used, but perfect cleanliness enjoined for the labia and parts adjacent. He had never had the misfortune of losing a patient after labor. The statistics from the large hospitals of the diminution of deaths since using the douche seemed, at first, to prove its value. Yet, after all, have we remembered sufficiently that coincident in time with the use of the douche there has been everywhere, especially in large hospitals, an endeavor, at least, to get absolute cleanliness of everything with which patients come in contact. These latter items certainly may have done as much as the douche toward this favorable result. It may be asked by some if they have not had the greater influence of the two. Dr. Bowditch thought that the reader had proved, and that the cases cited by other speakers of occasions when collapse of a serious nature, and even death, had occurred after the use of the douche by a trained nurse, amply supported the writer in the position taken, namely, that the operation should not be done in every case, but only in those in which the physician in attendance should deem it necessary as a remedial measure.

Dr. REYNOLDS remarked that it seems hardly just, in view of the wonderful advance in obstetrical knowledge which the last twenty years have seen, that a member who admits his withdrawal from all participation in these studies for a very long period should venture the sweeping assertions to which we have just listened. No one has a right to speak with clearer authority than that gentleman in those departments of medicine which he has by illustrious service made so peculiarly his own. Injuries at the circle of the os uteri, especially at the junction of the anterior and posterior lips, are in labor the rule, not the exception. How few primiparae escape without tearing more or less the perineal surface. Cattle die in giving birth as well as women. In the one case, as in the other, watchful attention, kindness, the intelligent use of means, spares illness and saves life. It is not humane to let the cows take their chance unprotected. Heaven forbid that we should think it of no greater importance to prevent the breaking down of women or their death!

Dr. SILVENS, of Cambridge, reported the case of a woman to whom vaginal douches were given after confinement through a Davidson syringe and a tube with no hole in the end. The douches were used daily, and were finally followed, on the ninth day, by very severe pain and collapse. The woman rallied, and there was a rise of temperature, followed by flowing. She continued to fail and died in three

weeks of septicemia. He is now cautious about using douches. If the lochia are offensive he gives instructions to the nurse about using them, and never permits their use without first so doing.

Dr. DRIVER said he does not believe in routine treatment. It may be wise to use the douche in hospitals, but in private practice he does not approve of its routine use. If the case is pathological he considers that the douche is indicated, and gives it himself if he does not have a trained nurse in attendance. He has seen pain and tenderness follow the use of the douche even when given by a trained nurse.

Dr. WINGATE remarked that it is his custom to use vaginal douches if the nurse is competent to carry out his instructions regarding them. He has not had any unfavorable symptoms arise from their use.

Dr. CHARLES P. PUTNAM said it had been claimed that the douche diminished the mortality in childbed, but were this not the case he should advocate the use of the douche in a crowded community, if only the mortality were not increased. In the country, especially if sparsely settled, putrefaction takes place slowly when compared with a large city where any material like blood putrefies with great rapidity, so that one can hardly say that any child-birth takes place under normal conditions. Douching in childbed might be compared with any of the so-called improvements of modern civilization. The question is not whether it is dangerous, but whether it is less dangerous than the neglect of it. So water-closets and waste-pipes are dangerous in houses, unless great care is taken that they be in good order and that one does not trap the other. But because traps have to be carefully ventilated, we do not abandon them for the still more dangerous vaults. The argument that labor is a physiological process had no weight with him, because life in many other respects is no longer physiological. Savages may require douching as little as they require sewerage. He could not agree with the essayist that the procedure was painful; he had always found that patients who had not been douched in former labors were glad to have it done. He could not agree with the opinion that the greatest safety was found in the tubes with several slanting holes.

The uterus is not likely to be found lying in the same direction as the vagina and the slanting stream would be as likely to shoot into it as the direct. He thought the best way was to have the opening of the tube at the end and very large so that the current at that point would be slower than anywhere else. In this way all swift currents were avoided, and the water flowed freely and slowly in every direction.

Dr. E. W. CUSHING observed that a difference of opinion bordering on asperity was apparent, which seemed to be owing to the different standpoints of the speakers. Those who practised in crowded localities, and especially in hospitals, were naturally more afraid of septic complications, and desirous of guarding against them, but this paper was not on the treatment of hospital cases, all of which are under peculiar conditions, but on the routine use of the douche in normal cases. It was written as an inquiry as to the duty chiefly of country

practitioners, who seldom see septic sequelæ of labor, and seldom have very well trained assistants as nurses. Are they to be considered negligent if not habitually using the douche in all normal cases? Now, admitting for a moment that what the hospital men say is true, that the puerperal uterus is to be considered as a great wound, like the stump of an amputated limb, the speaker would be bold enough to say that stumps and wounds in healthy persons in the country do not need antiseptics, still less the uterus after normal labors. The cases related here to-night, and one seen once by Dr. Cushing, showed that practically douching is dangerous with such nurses as most physicians are likely to have at command. A careful man will always avoid having serious accidents, and even deaths, attributable directly to a treatment which he has adopted on merely theoretic grounds. Against the authority of eminent persons, so dogmatically asserted to-night, may be set that of a medical man, perhaps even more eminent, who, although he lived more than twenty centuries ago, knew something of obstetrics and even of douches, and laid it down as an aphorism that the physician should try to be of benefit to his patient, but should be, at least, sure that he does no harm.

Dr. M. L. CHAMBERLAIN said that during the first ten years of his practice he did not use vaginal douches unless unfavorable symptoms developed. For the last five years he has used them regularly and believes in them, and latterly uses the Reservoir syringe only. Professor Lusk, in a recent lecture, reported a death immediately following a vaginal douche of hot water, by a bulb syringe, for hæmorrhage after a normal labor. He has since abandoned this form of syringe in obstetrical practice, and uses the Fountain apparatus. Dr. Chamberlain thinks that the accidents reported from vaginal douches are due to mechanical defects, and has invented a device, which will be shown to the society at its next meeting, that does away with the possibility of air being introduced into the uterine canal, and precludes undue force to the stream. The douche fluid is released in the posterior cul-de-sac — the most frequent site of infection. These douches purify the canal, and he believes in the consequent cleanliness.

Dr. MORRIS PRINCE thought that in discussing this question we must distinguish between the use of douches as a luxury and their use as a necessity. These two objects had been confused in the discussion. Douching the vagina was undoubtedly cleanly and added to the comfort of the woman, but when used for such purposes could only be looked upon as a luxury. The more important question was whether it was necessary to prevent disease. If it did the latter, the practitioner might feel in duty bound for the safety of his patient to use douches in every case of childbirth, even though it might be conceded there was some slight danger in their use. This was an important question for such physicians who practised among the poor where no conveniences are at hand, and the physician is compelled to give the douches with his own hands. Should such physicians regard it as their duty to give douches in every case, as had been asserted here to-night?

Dr. PRINCE's experience at the Temporary Home, where the most unfavorable cases were received, seemed to show that douches could hardly be regarded as a necessity. All the cases that come to the Home are in labor when they are received; most of them are deserted women; many have walked some distance while in labor; some have already given birth to the child in the public streets; all are in an unfavorable mental condition. Yet during Dr. Prince's service, the patients, with one exception, had invariably done well. He had never had a death, and he was informed that there had never been a death in the Home. The cases numbered about one hundred and fifty altogether. It was the custom in the Home to use douches only when the lochia were offensive, or there was a rise of temperature other than that of milk fever. This experience, so far as it went, seemed to go to show that douches were not a necessity, however great a luxury they might be. Dr. Prince did not wish to appear to give an opinion adverse to douches if one desired to use them.

Dr. RICHMONDSON replied, to a question by Dr. Garland, that he uses in giving douches a Davidson syringe and a tube without a hole in the end, or the Fountain syringe. He generally uses from a pint to a quart of a two per cent. solution of carbolic acid, at a temperature of 110° to 112° F. The tube should be inserted only a short distance into the vagina, and the fluid should pass in without force; then no trouble will be experienced. For a year and a half he had used, when on duty at the Lying-in Hospital, a solution of corrosive sublimate, 1 part to 2000, but he should hereafter use carbolic acid.

Dr. CHADWICK said that he had for years had the greatest faith in antiseptic douches in childbed and resorted to them in all cases where the labor had been terminated instrumentally or the soft parts had been extensively lacerated; likewise upon the supervision of fever or even foul lochia. He had seen no bad results; yet he had never felt that the practice was so devoid of danger as to be as warrantable as the uterine treatment after normal labor in private practice. The enumeration of so many cases in one evening, in which serious or fatal results had resulted from the practice, offered fresh evidence that the danger was by no means insignificant. He maintained that these mishaps could not be explained away by inveighing against the form of syringe used or the carelessness of nurses. There was no reason to doubt that the douches in these cases had been administered with as much care as could be expected, for the nurses had been graduates of the training-schools and lying-in hospitals. As to Davidson's syringe, the only serious objection to its use is its liability to admit air with the water. Now there is no evidence to show that the symptoms in these cases were due to the entrance of air into the uterine sinuses; in fact, the evidence is all against such an hypothesis. As to the practices in foreign hospitals, it has been demonstrated that the various antiseptic precautions taken have reduced the mortality marvelously, but it has not been made clear that the vaginal douche is one of the essential features of their methods. In illustration of this point he read a single extract from the last report of Dr. A. V. Macan, master of the Rotunda Hos-

pital in Dublin, whose diminished death-rate, he said, was as remarkable as any that had been made public. As this report had been quoted during the evening as illustrating the harmless and beneficial effects of the vaginal douche, the subjoined statement was peculiarly pertinent:—

"Hence, if the prophylactic precautions adopted during labor are sufficient, there can be no necessity for any prophylactic antiseptic injections, whether vaginal or uterine, in the puerperal state, and, as a fact, I never allow them to be used either in hospital or private practice. Indeed, I do not even consider it necessary to use an antiseptic solution for washing the external genitals, which is done twice daily with plain warm water, a piece of oakum taking the place of a syringe, a substitution the credit of which belongs to Dr. Atthill" (page 6).

Dr. ADAMS in summing up said the paper was perhaps indifferently composed or badly read, as some points seemed to have escaped the notice which he thought they deserved. The statistics to which he referred from Winckel he then read from the book itself, as translated by Dr. Chadwick. These statistics included considerably *more than half a million* cases treated in hospitals and showed that the mortality was four to five times greater than in private dwellings. That it was not adequate to cite, as some of the speakers had done, the experience of *one hospital* (the Rotunda, he believes), *during a single year*, and ask us to believe on this evidence alone that Winckel's statement was ill-founded. He hoped that no one thought that the variety of syringe used was a vital point in the question under discussion. Whether a "Davidson" or a "Fountain" syringe was used, it still remained true that it was essential to give considerable force to the stream of water if you wished to wash out the vagina. That to enter the point of the syringe not more than half an inch within the orifice, or to give to the stream only the force of a column of water a foot in height, could not be called "douching the vagina." Such methods could not effect more than simply to wash out the *orifice* of the vagina. It had been denied that the process was *ever* painful. He could only say that he had frequently found that pain was complained of on merely placing the finger gently within the os tium vaginæ preparatory to passing the catheter to relieve retention. He agreed with Dr. Reynolds that rents or tears were frequent, especially in primiparæ, about the vaginal orifice. These readily healed if let alone, but if disturbed, by washing or otherwise, the process of repair might be delayed and the period of auto-infection by these wounds be thus prolonged. He then referred to a discussion on this subject in the seventh International Congress, and quoted Professor Tarnier, of Paris, who said that he himself *never used the douche so long as everything went well*. He also quoted Dr. Munde, who, at the New York State Medical Association said, speaking of the antiseptic intra-uterine douche: "It is useless and sometimes positively injurious, first, *where the lochia are not at all offensive*." Dr. Garrigues said that he had been disappointed in the douche in the Maternity Hospital, since, in spite of its use in the most thorough manner, there had been many cases of puerperal fever. He said that if we wished to draw a line

between the healthy condition, where the douche is not only useless but positively injurious, and the unhealthy, in which the douche may be of the greatest service, such line may very properly be placed at *fetid lochia*. So long as the lochia are not offensive the douche, in his opinion, had better be let alone.

In the *Journal of the American Medical Association*, vol. iii., No. 16, is an article by Dr. Wm. T. Lusk, of New York, on "Sudden death in labor and childbed," in which he says: "Air may be forcibly driven into the uterus by means of the uterine or even the vaginal douche. For this reason the syphon syringe ought to be discarded from midwifery practice. It is never a safe instrument, and I have prohibited its employment in all the public institutions with which I have been connected."

"It is not necessary that the nozzle of the syringe should be introduced directly into the uterine cavity for accidents to occur."

"In a case reported by Wiener in Spiegelberg's clinic, where the tube of the douche apparatus was free from air, collapse resulted from the hydrostatic pressure forcing air previously introduced into the vagina up into the uterine cavity."

## THE NEW YORK ACADEMY OF MEDICINE.

STATED meeting, February 5, 1885. A number of gentlemen from a distance, including Drs. S. Weir Mitchell and Theophilus Parvin, of Philadelphia, John S. Billings, U. S. A., of Washington, and James R. Chadwick and George B. Shattuck, of Boston, were present on this occasion, when Dr. FORDYCE BARKER delivered his

### VALEDICTORY ADDRESS,

on retiring from the presidency of the Academy. He was followed by Dr. A. JACOB, the President-elect, who made his

### INAUGURAL ADDRESS.

In it he paid a tribute to his gifted predecessor, and expressed the hesitancy which he felt in venturing to occupy the position which he had relinquished. He trusted, however, that he would receive the cordial support of all in his efforts for the welfare of the Academy, and that every individual would consider the interest of the institution as his personal charge. Having spoken of the differences between this and the Academies of Medicine in Europe, which were exclusive, and whose membership was limited to a comparatively small number of men who were distinguished in special departments, while this was of a democratic character and open to all reputable medical men, he said that here all were engaged in active practice instead of devoting themselves entirely to study. This was also the case in Great Britain, and among Anglo-Saxons it had always been the aim of all medical science to accomplish the practical result, or relieving suffering and curing disease. At the same time, he said, no little original work had been accomplished by the profession in America, and the history of modern medicine would be very incomplete without a reference to the names and labors of such men as Bard, Rush, McDowell, Drake, and Beck. In this

connection Dr. Jacobi mentioned a long list of distinguished physicians and surgeons, now deceased, whom he had had the opportunity of personally meeting.

A greater interest, he thought, should be manifested in the Academy on the part of the profession at large. There was too much division and too large a number of societies, it seemed to him, and there was no good reason why the various special medical organizations in New York should not be made sections of the Academy, thus increasing the efficiency and usefulness of that institution, while they could still practically retain their independence. The mixture of the "best brains" and the modest practitioner, such as was seen in the fellowship of the Academy, was capable, he believed, of materially elevating the general standard of the profession. The earnest coöperation of both old and young was desirable for the best success of the institution, for books and brains with experience were a greater power than books and brains without experience. Well might all emulate the example of the Nestor of New York surgeons (the venerable Dr. Alfred C. Post, who occupied a seat on the platform), who was seldom absent from a meeting of the Academy. The time would yet come, he continued, when the profession would have more influence in the community than at present,—when the President of the Board of Health would be nominated by it, when no school-board would be without a physician among its members, and when medical men would actually have something to say in the management of hospitals.

Dr. Jacobi then gave a *résumé* of the history of medicine from the beginning of the eighteenth century down to the present time in France, Germany, England, and America, maintaining that it was entirely the Anglo-Saxon mind that shaped the medical thought of that century. In describing the condition of affairs in Germany just before the brilliant era of Virchow, he said that the people very naturally preferred the homœopathic's little pill to the pathologist's post-mortem box.

Dr. Jacobi next took up the topic of bacteriology, which he treated in rather a disparaging manner. It required considerable courage at the present day, he said, to resist the flood of popular opinion in the profession, but there were some competent observers in America who had taken a stand of this kind. To himself, while no one thought more of pathological knowledge in general than he, it had always seemed that purely bacteric pathology often begged the question. With the rapid advances that were continually being made in the study of organic chemistry it appeared to him more and more probable that some at least of the acute infectious fevers were due to chemical rather than bacteric agents. In this connection the subject of cadaveric poisoning was of great interest, and it was pertinent to inquire whether the poisonous agent might not originate before death. More than once it had occurred that several bacilli were successively announced as beyond doubt the real cause of some disease, so that it seemed altogether probable that some of them were such. Thus, three different microbes had at different times been assigned as the *contagium vivum* of diphtheria by as many authorities, and the matter was becoming

rather ludicrous. A dozen years ago a whooping-cough coccus was discovered, and at the same time it was announced that quinine was an infallible destroyer of it; but notwithstanding all this *accurate* knowledge of the disease and its treatment, it could hardly be said even yet that the affection had been stamped out of existence. Bacteric microscopy in the hands of beginners was exceedingly noisy and self-opinionated, and there was an immense amount of speculating going on all the time in Germany, where it was a very common thing to see in the medical journals "preliminary announcements" of discoveries which are not as yet *completely* substantiated, but the glory of which their authors apparently feared might be wrested from them by some other ambitious investigator.

In concluding, he spoke again of the excellent work accomplished by American physicians, and referred particularly to the fact that Dr. Oliver Wendell Holmes had pointed out the communicability of puerperal fever four years before Semelweis announced its contagiousness in Europe.

#### LETTER FROM DR. HOLMES.

When he had finished his address, the new President introduced Dr. Chadwick, of Boston, who presented to the Academy a copy of the latest photograph taken of Dr. Holmes, and then read a letter written by him to Dr. Barker in reference to his withdrawal from the presidency. This little episode was entirely unexpected on the part of Dr. Barker, and it formed one of the pleasantest features of a very enjoyable evening.

### Recent Literature.

*Osteotomy and Osteoclasis for Deformities of the Lower Extremities.* By CHARLES T. POORE, M.D., Surgeon to St. Mary's Free Hospital for Children, New York. New York: D. Appleton & Co. 1884.

We have rarely read a book to which we can accord more praise than this carefully prepared volume. Osteotomy and osteoclasis are operations which have of late become quite popular. Yet there is a large class of surgeons who have not kept pace with the times, to whom this volume is especially commended. This class of men, either from indifference or a self-sufficient conservatism, refuse, perhaps wisely, to accept facts as principles until the experience of others has sifted the chaff from the wheat.

Dr. Poore has collated the facts bearing on osteotomy and osteoclasis. A large personal experience in the operation has enabled him to put before us the results of these operations in a very satisfactory manner.

The charm of the monograph to us lies in the completeness of its references and the fairness of spirit manifested in judging of the merits of each method of operating. Yet at the proper time Dr. Poore asserts his own views and preferences, so that no one is left with a jargon of methods.

A typographical error in a numeral exists on page 52, line 16, which makes the result of an operation antedate the operation itself.

We most heartily commend this volume to the reading of all surgeons.

E. H. B.

# Medical and Surgical Journal.

THURSDAY, FEBRUARY 19, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by CUPPLES, UPHAM & CO., Boston. Price, 15 cents a number; \$5.00 a year, including postage.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUPPLES, UPHAM AND COMPANY,  
283 WASHINGTON STREET, BOSTON, MASS.

## FIRES IN INSANE HOSPITALS.

SEVERAL years ago we took occasion to point out to our readers the not infrequent fires in hospitals for the insane, and we particularly urged that precautions should be taken to guard against such fires in other institutions.

Fortunately, Massachusetts has as yet been spared such a catastrophe by fire, but the number of recent conflagrations in other States, attended in two instances by a large loss of life, again makes it proper to draw attention to the subject.

Two of these fires were at the Indiana Hospital for the Insane, which contains about seventeen hundred patients. The first one, which occurred on the thirtieth of December, in one of the wards, would have been followed by many deaths but for very prompt action on the part of the officials. The money loss on the second fire, which occurred January 27th, was considerable. The third fire occurred on January 18th, in the South Infirmary of the Illinois Eastern Insane Hospital, at Kankakee, and was attended by a large loss of life.

This infirmary was a two-story building of brick and stone, with no wood except the floors and stairs, and held forty-five patients. The newspapers state that "there were no facilities for putting out fire, the State having made no appropriation for the purpose."

Had the building been properly constructed as to floors and stairs, and had it been provided with fire apparatus, as all institutions should be, before occupation, Illinois would not now have to mourn so large and unnecessary a sacrifice of human life.

One of the chief advantages of the isolated building plan for the insane hospital should be that a fire will thereby be confined to the narrowest limits both as to space and number of inmates, and it is to be hoped that the moral of the Kankakee fire will be to point out more exactly what such buildings require to make them absolutely fire-proof.

The fourth and last fire, that in the insane department of the Philadelphia almshouse, is fresh in the minds of all. Since Dickens wrote his "American Notes," the "Blockley Almshouse"

has unfortunately not possessed, to say the least, an enviable reputation, and the destruction of its insane department, with the loss of eighteen or more lives, brings down the curtain on the lurid and terrible glare of the end of its existence, which is, perhaps, not altogether inappropriate.

The most incomprehensible feature of the Philadelphia tragedy seems to be, if we may trust the newspapers, that a very appreciable number of the patients who were burned at the stake, as it were, or those who escaped, were bound with chains, either by hand or foot. The cells in the third story were bad enough, but the chains in these days of advanced treatment of the insane seem like a return of the days of barbarity practised at the beginning of the century.

If Philadelphia should erect another institution for her insane, it is to be hoped that it will not be an almshouse, or managed on the almshouse plan, for the combined experience of the best experts, as well as the present condition of large numbers of almshouses, prove to our minds conclusively, that only medically educated men can so appreciate the nature of the *disease* insanity, and the needs of the insane, as to successfully care for them.

We are glad to see that large numbers of the former Philadelphia almshouse insane are being transferred to the Pennsylvania State Hospital. To them the recent horrible fire is after all a blessing in disguise.

In conclusion, may we not beg all our Legislatures to see to it that as far as they are concerned no stone shall be left unturned to guard public institutions against fire?

Why should not Massachusetts, at least, have a law in her statute-books that no new building should be occupied as a dwelling-place for any of those in her care, until a report had been made in writing to the governor by a proper board of fire experts, that it was fireproof and thoroughly provided with fire apparatus?

Our turn may come next, and the present winter is none too soon to establish such a law.

## EXPERIMENTAL PNEUMONIAS.

It is worthy of note that of all the numerous attempts which have been made to induce artificial pneumonia in animals under experimentation, none have ever resulted in the production of a pulmonary inflammation identical with true fibrinous pneumonia, otherwise called "frank" or "croupous" pneumonia, — "lobar" pneumonia. Bretonneau tried the effect on hares of irritant-acid vapors, such as hydrochloric acid; the animals were confined in barrels where they were exposed to these fumes for a considerable time, being rescued only at the point of death. They were shortly afterward killed, and a careful examination made of the pulmonary

lesions. Both lungs were strewn with ecchymosed patches, and in the centre of the congested tissue were nodules of lobular hepatization. Similar experiments were made with ammonia and chlorine; in some instances nitrate of silver was injected into the bronchi; Cornil used turpentine. The results were negative in effecting anything resembling lobar pneumonia; only bronchitis and islets of broncho-pneumonia succeeded the local application to the air-passages of these irritating chemical agents.

Hohenheimer injected septic fluids, such as putrefying blood and pus, into the bronchi of dogs on which he had practised tracheotomy; he thus determined lobular pneumonias, or pseudo-lobar broncho-pneumonias. Wolff obtained similar results from the injection into the bronchi of hares and Guinea-pigs of fluids containing the ordinary bacteria of putrefaction.

Kuhn injected into the subcutaneous cellular tissue of adult hares pneumonic sputa diluted with water; the symptoms which followed were those of true septicaemia and not pneumonia.

Heidenhain finally essayed to produce experimentally a fibrinous inflammation of the lungs by exposing his animals to sudden severe chilling, after they had been overheated. He obtained "tracheitis, bronchitis, nodules of lobular pneumonia, but in no case did he observe anything resembling lobar pneumonia, or the concomitant pleurisy."<sup>1</sup>

It has been remarked that traumatism of the lung in animals, as wounds of the pulmonary tissue in man, have failed to provoke the lesions and symptoms of ordinary frank pneumonia.

Sections of both pneumogastric nerves above the origin of the inferior laryngeal, and sections of the inferior laryngeal nerves alone, have produced sanguineous engorgement and oedema of the lung, with here and there indurated nodules of gray hepatization; there was always accompanying bronchitis with turgescence of the mucosa and abundance of muco-pus, and the microscope has revealed proliferating endothelium and round (embryonic) cells stuffing the alveoli, besides peri-bronchitis and peri-arteritis,—but never a clearly defined fibrinous exudation. These lesions, called by German writers *lobular broncho-pneumonias by aspiration*—the fact being that they owe their origin not so much to vaso-motor troubles, as to foreign bodies, such as vegetable cells, animal hairs, food particles sneaked into the bronchi during inspiration and remaining there to provoke irritation; the nervous mechanism of expulsion being put *hors de combat* and paralyzed by division of its nerve—these lesions, we repeat, are in no sense those of frank lobar pneumonia.

Talamon and Sée, from whose interesting work<sup>2</sup> we have drawn largely for these facts, plead strongly

in favor of their present view which makes pneumonia a primarily local disease, due to an infectious living agent, which under certain circumstances effects a lodgment in the lungs, and there by its irritating presence produces a specified inflammation with severe febrile reaction and general constitutional perturbation.

Among other powerful arguments, the utter failure of experimentation to produce the disease in question is a striking corroboration of this theory in the abstract. It is, however, not unlikely that we may still have to await the differentiation of the specific organism, and we would not be understood, as might fairly be inferred from an editorial paragraph on page 116 of this volume, to regard the causal relation of any particular microorganism to pneumonia as definitely established.

#### THE ROUTINE USE OF THE VAGINAL DOUCHE AFTER NORMAL CHILDBIRTH.

SINCE this subject was brought prominently to the notice of the profession a year ago by Professor T. G. Thomas, in his memorable paper on the prevention and treatment of puerperal fever, much has been written both in favor of, and in opposition to, the routine use of the douche in normal childbed. A critical review of this literature is not our present purpose, but rather a brief consideration of the subject as presented at a recent meeting of the Obstetric Section of the Suffolk District Society, a report of which appears in another column.

The reader's objections to the douche in normal childbed were that it is artificial, meddlesome, of doubtful utility, that it may be hurtful and even fatal; and the discussion which followed the able introduction of the subject well illustrated the wide diversity of opinion regarding the value of the douche as a prophylactic measure, and the dangers and disadvantages of its use. That the douche has been hurtful, and even fatal, no one will deny; the same may be said of other simple procedures in incompetent hands; and the careful practitioner, whatever his opinion of the utility of the douche, should not subject his patient to possible harm from the careless use of this, any more than of other, therapeutic or prophylactic measures. We believe, however, that the fountain syringe or irrigator, fitted with a vaginal tube having large lateral apertures, may be used with entire safety, provided the tube is not introduced too far and the reservoir of water is not raised too high. It is a wise precaution, too, to introduce the tube with the water running; the entrance of air is thus effectually prevented. The risk of forcing effete material into the uterus we believe to be entirely imaginary, unless improper force is given to the afferent current.

The idea that the douche is artificial and meddlesome is based on the theory that parturition is a physi-

<sup>1</sup> G. Sée, *Maladies Spécifiques des Pouxmons*, page 81.

<sup>2</sup> *Des Pneumonies Algériennes*, Paris, 1885.

ological process and that in normal cases the medical attendant should be merely an intelligent spectator; this theory was vigorously opposed by some in the debate and we think justly so. It seems unnecessary to point out that modern civilization has transferred the parturient woman of the nineteenth century from the physiological status of primitive times to one, which, if not pathological, is certainly beset with many dangerous possibilities. The cry of "meddlesome midwifery" is constantly raised against those who seek to prevent the dangers and palliate the sufferings of normal labor; however justly in other respects, in regard to the douche we can only say that, so far from being painful and annoying, we have always found it considered as comforting and refreshing.

But the vital point at issue seems to be the question of utility. It was pointed out in the discussion that Macan, of the Dublin Rotunda, obtained his extremely favorable results without the aid of the vaginal douche in normal cases; but it should be remembered that Macan employs such extreme antiseptic precautions<sup>1</sup> that he considers the douche simply superfluous. The same may be said of Garrigues, who, in his service at the Maternity Hospital on Blackwell's Island, after the most scrupulous precautions before and during labor, applies to the vulva post partum an antiseptic pad "with the same special care that would be used in dressing a wound after a capital operation"; and this dressing is changed every six hours.<sup>2</sup> Under such circumstances Garrigues regards the douche as unnecessary. In private cases these extreme precautions are seldom feasible and in the purer air of country practice are perhaps unnecessary; but in cities and large towns, where impure air and unsanitary plumbing are a constant source of danger, the douche may be of incalculable value in lieu of the stricter precautions found necessary in hospitals. We should say, therefore, in conclusion, that the vaginal douche in normal childbed, when given by competent hands and with proper apparatus, is not dangerous nor even hurtful; that it affords a refreshing sense of cleanliness and well-being to the patient; that it promotes the healing of abrasions and lacerations; and that it may be the means of preventing infection.

#### HOSPITAL ACCOMMODATION FOR CONTAGIOUS DISEASES.

THE need of better and more extensive accommodation at the Boston City Hospital for the care and isolation of contagious diseases has long been felt by the medical and surgical staff connected with the hospital, and by physicians in general practising in the city, who have occasion to send patients to that institution.

Eighteen rooms, eighteen to twenty feet square, containing seventy-two beds, in a three-story building, constitute the only accommodation for all the noisy, delirious, offensive medical and surgical cases occurring among 250 patients, and for all the cases of contagious disease—except small-pox—which cannot be treated at home, out of a population of 430,000.

It would seem as if this bare statement should be sufficient to incite the city government to immediate action in the premises.

The community at large begins to realize, only less keenly than the medical profession, the importance of isolation and disinfection in dealing with contagious disease, and the double nature of the blessing which flows from suitable hospital provision for them. The care and cure of the individual case is after all a small good compared to the avoidance of extensive epidemics. Our brethren of the daily press have rarely used their energies to better purpose than in concentrating attention upon this point.

#### MEDICAL NOTES.

—The *Australian Medical Gazette* for December 15, 1884, contains four very instructive and interesting photographs of the efflorescence in cases of variola.

—*Science* proposes a new fireproof building for the use of the various scientific societies of Boston, and suggests as an eligible location a part of the lot adjacent to that secured for the new Public Library and next to the Harvard Medical School. "Bowditch Hall" is the name proposed for the new edifice.

—The condition of the two policemen, Cox and Cole, who were the chief sufferers from the recent dynamite explosion in London, is thus given in an English contemporary: Their appearance on admission to the Westminster Hospital indicated clearly the violence to which they had been subjected. Their clothes were torn into shreds and scarcely hung together, while the helmets were damaged almost beyond recognition. The leg of one of the men's trousers was blown completely off, although the leg was apparently uninjured. The men were suffering severely from the shock, and were much prostrated. Cole, in addition, was found to have four ribs broken, presumably from coming violently into contact with some projecting angle, though he was carrying the packet just before the explosion. For some time after admission, too, his urine was tinged with blood. They soon rallied considerably from the shock and partially recovered their hearing and other natural senses, which were in complete abeyance on admission, and from the loss of some of which they will probably suffer for the rest of their lives. Their temperatures at the time of the

<sup>2</sup> See vol. cx., No. 1, page 14, of this journal.

report were nearly normal, and there was every reason to hope that they would accomplish a speedy recovery.

#### NEW YORK.

— The report of the Department of Public Works for the year ending December 31st last was sent to Mayor Grace on the fourth of February. The rainfall in the Croton watershed for the year was 53.71 inches, which has been exceeded only in the years 1878 and 1882 since 1865. At the same time there were several periods of extreme dry weather, when 2,040,000,000 gallons of water had to be drawn from the two storage reservoirs and several lakes to supplement the natural flow of the Croton River, in order to keep the aqueduct fully supplied. All the lakes and reservoirs are now full, and an additional water-supply of about 10,000,000 gallons is at present received from the Bronx River. The average quantity of water supplied per day through 10,905 meters is 20,060,600 gallons. The excessive water which occurs in cold weather through the habit of letting water run from faucets day and night to prevent freezing in the pipes is shown by the fact that in a single cold day, December 20th, the Central Park reservoir was drawn down five inches, indicating an excess of 13,000,000 gallons used on that day over the ordinary consumption, and over the supply received from the aqueduct.

— Under the direction of Dr. Cyrus Edson, of the Sanitary Bureau, a strict investigation into the purity of the drugs sold by the apothecaries has been commenced. Forty samples of quinine have been purchased from various establishments for analysis, and the first arrest for adulteration was made on February 2d. It was that of a druggist in Third Avenue, the quinine purchased from whom was found to be adulterated with a large quantity of sugar of milk. He was charged with violating section 16 of the Sanitary Code, and was admitted to bail.

— Dr. James Owens Smith died January 30th at the age of eighty-two years. He was born at Coxsackie, Greene County, N. Y., and was graduated from the College of Physicians and Surgeons, New York, in 1825. At this time the Republic of Columbia, then recently established under the presidency of Bolivar, was engaged in endeavoring to build up a navy, and Dr. Smith secured the position of surgeon (for which there were no less than seventy applications) on a frigate purchased in the United States, and about to sail for Venezuela. On arriving at Caracas it was found that yellow fever was fiercely raging, and, some of the local physicians having died and some having deserted their posts, there was an instant demand on the part of the inhabitants for the ship's surgeon. Dr. Smith entered upon the work with energy and determination, and his labors were crowned with success. He caused strict sanitary precautions to be ob-

served, closed the drinking-saloons, and finally brought the disease under control. The inhabitants of a neighboring city, also suffering from the scourge, then sent for him, and he succeeded in successfully combating the fever there too. Sir Robert Ker Porter, the artist and traveler, at that time British consul at Caracas, made Dr. Smith his physician, and he practised there for the next five years. He then returned to New York on account of the death of his father, and, although earnestly entreated to return to Venezuela by Sir Robert Porter and many others, he decided to remain in that city. Scarcely had he settled in New York, in 1832, when the cholera broke out. His active labors during this epidemic at once brought him an extensive practice, and he remained engaged in full professional work in the city until fifteen years ago, when he retired. Dr. Smith never married. He was a Fellow of the Academy of Medicine, and was prominently connected with Grace Church, where his funeral took place February 2d.

## Correspondence.

### LETTER FROM VIENNA.

VIENNA, January 17, 1885.

To American physicians studying in Vienna the clinic of Professor Billroth is the chief surgical attraction. The material is very abundant and there are two operating-tables in the amphitheatre, both being often in use at the same time. Nearly all the ordinary operations are performed by the assistants, of whom there are constantly six or eight present. Professor Billroth directs and describes the operations, explaining all important points and making frequent use of the blackboard to illustrate pathological states, operations, mechanical appliances, etc., and so often gives the greater portion of his lecture while operations are being made by the assistants, thus doubly occupying the time. The clinic is of two hours duration daily, and a large number of cases are usually disposed of each day, and several important operations may occur at one clinic.

I had the pleasure of witnessing an excision of the stomach made by Billroth, January 15th, which operation I will briefly describe:—

A male patient, aged about fifty, with scirrhus of the pylorus and presenting the history usual to such cases, was anesthetized and the abdominal cavity opened by an incision about five inches long in the median line directly over the stomach. After a careful examination of the tumor and its relations to the surrounding organs, the greater curvature of the stomach and that portion of the small intestine most convenient for the purposes in view were lifted out of the abdominal cavity and held by assistants while an opening was made in each and their edges so united by sutures as to leave a free communication between the cavity of the stomach and the intestine in this position, this gastric opening being of course through the healthy

tissue not far distant from the diseased portion to be removed. The intestinal opening was made about sixteen or eighteen inches distant from pylorus. The diseased end of the stomach was then separated from its attachments, many vessels being ligated and then, together with the surrounding tissues, cut through either with the scissors or thermo-cautery. That portion of the lesser omentum attached to this portion of the stomach was so cut through. The duodenum was now divided near the pylorus and its cut end closed with sutures. The pyloric end of the stomach, into which a sponge had been crammed to prevent the escape of its contents, was now elevated by the assistant and the incision through the stomach made from below upward, or, in other words, from the greater to the lesser curvature. Let it be remembered that the stomach was without the abdominal cavity and so held as to keep the anterior and posterior walls in contact. When the knife had reached a depth of about one inch, or made an opening in the stomach two inches long (please bear in mind that both anterior and posterior walls are cut at the same time), the knife was laid aside and these two walls stitched together to this extent; then the incision was extended an inch further and again stitched, and so on until the whole organ was cut through and the cut edges of the anterior and posterior walls carefully united. The abdominal cavity was carefully cleansed and the wound united in the usual manner and dressed antiseptically. The portion removed was as large as, and shaped much like, a man's fist seen to the wrist-joint. The operation consumed one hour and forty minutes. At last report, twenty-four hours after the operation, the patient was encouragingly comfortable.

Respectfully,

GEO. W. DAVIS, M.D., *Holyoke, Mass.*

#### MRS. DR. HUDSON. — A WARNING.

Boston, February 14, 1885.

MR. EDITOR. — On Wednesday, a lady, calling herself Mrs. Dr. Hudson, called at my office, stating that, until his death, she had been the amanuensis of the late Dr. J. Marion Sims.

She was very anxious to raise one hundred dollars to pay the interest on the mortgage on her furniture. Several doctors had aided her, and she hoped I would contribute ten dollars, which would, of course, be repaid in ten days, when she was to receive some money.

As I never knew a deserving person to solicit funds of strangers, without at least a letter of introduction, I declined. Thinking it a case of fraud, I send you the facts, to be used if you see fit, should you hear of similar calls, as the lady seemed to be making a pilgrimage among the doctors.

Yours truly, Wm. L. RICHARDSON.

#### TREATMENT OF FRACTURES OF THE FEMUR WITHOUT SPLINTS.

DOVER, N. H., February 6, 1885.

MR. EDITOR. — I notice in your issue of yesterday an article on the treatment of fracture of the

femur without splints, which treatment, the writer says, was originated by Dr. John Swinburne, of Albany, N. Y., and which was published by him, in 1861, in the Transactions of the New York Medical Society.

The writer says he "has never seen a word in print on the subject since 1861," and wishes to call the attention of the profession to it. The Treatise on Surgery of Prof. Samuel Gross, of Philadelphia, page 958, vol. i., edition of 1864, contains a description of Dr. Swinburne's treatment, *in extenso*, with an engraving illustrating the applied dressing, and with an allusion to the "upwards of forty cases" treated by Dr. Swinburne.

Yours truly, JOHN R. HAM, M.D.

#### Miscellany.

##### PUBLIC HEALTH IN WEST VIRGINIA.

IN his last message to the Legislature, the Governor of West Virginia refers to the State Board of Health in the following complimentary terms: —

"It is with pleasure that I direct your attention to the operations of this department of the State service. The act of the Legislature establishing the State Board of Health has become popular with all classes of our people. It has been taken as a model for similar legislation in several of the sister States, and the industrious and intelligent labors of the Board have won much credit for West Virginia."

##### IS THERE A CORRELATION BETWEEN DEFECTS OF THE SENSES?

PEOPLE sometimes assume, remarks Prof. Alexander Graham Bell, in *Science* (February 13, 1885), that a defect of any important sense is balanced to the individual by the increased perception of the remaining senses. For instance: it is often thought that deaf persons have better eyesight than those who hear, and that blind persons have better hearing than those who see. The returns of the tenth census of the United States (1880) concerning the defective classes show clearly the fallacy of such a belief. They indicate that the deaf are much more liable to blindness than the hearing, and the blind more liable to deafness than the seeing.

About one person in every thousand of the population is blind, and one in every fifteen hundred deaf and dumb. Now, if these proportions held good for the defective classes themselves, we should expect to find one in a thousand of the deaf-mute population blind, or one in fifteen hundred of the blind population deaf and dumb; in other words, we should expect to find no more than thirty-four blind deaf-mutes in the country; whereas, as a matter of fact, no less than four hundred and ninety-three blind deaf-mutes are returned in the census.

Tables are given, compiled from the census returns, which seem to indicate that in the case of deafness, blindness, idiocy, and insanity, some correlation exists; for persons having one of those

defects appear more liable to the others than persons normally constituted, and doubly defective persons appear to be more liable to be otherwise defective than persons having a single defect. For instance:—

(a) Of 50,155,783 persons in the United States, 246,816, or 0.492 per cent., are defective.

(b) Of 246,816 defective persons, 4,597, or 1.86 per cent., are doubly defective.

(c) Of 4,597 doubly defective persons, 247, or 5.37 per cent., are trebly defective.

The most marked correlation seems to exist between deafness, blindness, and idiocy. There are

fourteen and a half times as many blind persons among the deaf and dumb in proportion to the population as among the community at large, and forty-six times as many idiotic.

There are fourteen times as many deaf-mutes among the blind in proportion to the population as there are among the community at large, and nineteen times as many idiots.

There are forty-three times as many deaf-mutes among the idiotic in proportion to the population as there are in the community at large, and eighteen times as many idiotic.

## REPORTED MORTALITY FOR THE WEEK ENDING FEBRUARY 7, 1885.

Deaths reported 2,208; under five years of age, 766; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrheal diseases) 315, lung diseases 367, consumption 343, diphtheria and croup 91, scarlet fever 48, measles 26, typhoid fever 33, malarial fevers 22, diarrheal diseases 28, whooping-cough 18, erysipelas 18, cerebro-spinal meningitis 13. From *measles*, New York 30, Boston 3, Philadelphia one. From *diarrheal diseases*, New York 11, New Orleans 7, Boston 3, Baltimore and Nashville two each. From *malarial fevers*, New York 3, New Orleans 8, Philadelphia and Baltimore two each. From *whooping-cough*, New York 10, Philadelphia and New Haven two each, District of Columbia, Lawrence, Somerville, and New Bedford one each. From *erysipelas*, New York 6, Philadelphia and Baltimore 1 each, Boston two, District of Columbia one. From *cerebro-spinal meningitis*, New York 3, Philadelphia and New Haven two each, Fall River one. From *pneumonia*, Fall River 3, Philadelphia, New Orleans, District of Columbia, Lowell, and Worcester one each.

In 110 cities and towns of Massachusetts with an estimated

population of 1,445,519 (estimated population of the State 1,355,000), the total death-rate for the week was 19.15 against 15.00 and 18.54 for the two preceding weeks.

For the week ending January 24th, in the Swiss cities, there were 40 deaths from consumption, lung diseases 10, diarrheal diseases 10, diphtheria and croup 10, whooping-cough 5, small-pox 2, measles 2, erysipelas 2, typhoid fever 2. The death-rates were: at Geneva 21.3; Zurich 5.8; Basle 18.9; Berne 26.2.

In the 28 greater towns of England and Wales, with an estimated population of 8,006,416, for the week ending January 24th, the death-rate was 21.0. Deaths reported 1491: infants under one year of age 880; acute diseases of the respiratory organs (London) 543, whooping-cough 112, measles 89, scarlet fever 17, fever 28, diphtheria 32, small-pox (London 43, Birmingham, Liverpool and Bolton one each) 46. The death-rates ranged from 16.1 in Brighton to 10.9 in Cardiff; Birkenhead 20.7; Birmingham 26.0; Blackburn 17.6; Bradford 20.0; Hull 19.6; Leeds 19.0; Leicester 20.9; Liverpool 28.2; London 27.1; Manchester 28.0; Nottingham 33.1; Sheffield 21.4; Sunderland 26.2; in Edinburgh 20.2; Glasgow 32.8; Dublin 31.9.

The meteorological record for the week ending February 7th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Date.	Barom-eter.	Thermometer.			Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FEBRUARY 7, 1885.

LONG, W. H., surgeon. Relieved at Detroit, Mich., to proceed to Chicago, Ill., and assume charge. February 4, 1885.

GODFREY, JOHN, passed assistant surgeon. To proceed to Vicksburg, Miss., and Memphis, Tenn., as inspector. February 6, 1885.

BENNETT, P. H., assistant surgeon. To assume temporary charge of the service at Detroit, Mich. February 4, 1885.

WILLIAMS, L. L., assistant surgeon. To report to the officer in charge at Detroit, Mich., for temporary duty. February 7, 1885.

#### RESIGNATION.

MILLER, T. W., surgeon. Resignation accepted by the Secretary of the Treasury, to take effect March 1, 1885. February 4, 1885.

#### PROMOTION.

GODFREY, JOHN, passed assistant surgeon. Promoted and appointed surgeon by the Secretary of the Treasury from March 1, 1885. February 6, 1885.

#### APPOINTMENT.

WILLIAMS, L. L., M.D., of South Carolina, having passed the examination required by the Regulations, was appointed an assistant surgeon by the Secretary of the Treasury, February 6, 1885.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM FEBRUARY 7, 1885, TO FEBRUARY 13, 1885.

TOWNS, F. L., major and surgeon. Granted leave of absence for twenty days. S. O. H., Department of Texas, February 1, 1885.

WILSON, WM. J., captain and assistant surgeon. Ordered for duty as post surgeon, Fort Pecos, Tex. S. O. 27, Department of the East, February 5, 1885.

WOODRUFF, E. L., captain and assistant surgeon. Ordered from Willet's Point, New York Harbor, to Department of Dakota.

TAYLOR, MARCUS L., captain and assistant surgeon. Ordered to the Department of the Missouri. S. O. 30, A. G. O., February 5, 1885.

ROBINSON, S. Q., captain and assistant surgeon. From Portland, Oregon, to his proper station, Fort Spokane, W. T. S. O. 29, Department of Colorado, February 2, 1885.

#### SOCIETY NOTICE.

NORFOLK DISTRICT MEDICAL SOCIETY. A meeting for scientific improvement will be held in "Social Hall" (Tremont Temple Building, Boston), entrance at 74 Tremont Street, on Tuesday, February 24, 1885, at 7.45 P. M. Subject for discussion: Pneumonia. Communications: "A Report of a Case of Gastric Anemia," L. Peabody Gerry, M.D., Jamaica Plain.

GEORGE D. TOWNSEND, M.D., Secretary, Roxbury, February 17, 1885.

#### DEATH.

DIED.—In Fall River, February 12, 1885, Ebenezer Turell Learned, M.D., M.M.S.S., aged seventy-two years.

#### RESIGNATION.

DR. C. M. GREEN has resigned his position as Surgeon to Out-Patients at the Free Hospital for Women.

#### BOOKS AND PAMPHLETS RECEIVED.

Consumption: Its Nature, Causes, Prevention, and Cure. By J. M. W. Kitchen, M.D. New York: G. P. Putnam's Sons, 1885.

Report of the Chief of the Bureau of Medicine and Surgery, Navy Department. Surgeon-General.

School Hygiene in Relation to its Influence upon the Vision of Children, or School Sanitation. An Address delivered before the Medical Association of Georgia, 1884, by A. W. Calhoun, M.D., President. Atlanta, Ga. (Reprint.)

The Medical Student's Essentials of Physics. By Condit W. Cutler, M.D., late House Physician, Bellevue Hospital, etc. New York: J. H. Vail & Co. 1884.

Orthopedic or a Practical Treatise on the Aberrations of the Human Form. A second edition, much enlarged, with additional Engravings and several Colored Lithographs. By James Knight, M.D. New York: J. H. Vail & Co. 1884.

The Role of Bacteria in Infectious Diseases. By Henry O. Marey, A.M., M.D., Boston. (Reprint.) Read before the American Academy of Medicine, Baltimore, October 28, 1884.

Denison's Seasonal Climate Map of the United States. Graphically illustrating combined Humidity Statistics with Isotherms, Wind Statistics, and Seasonal Tables. Compiled from Data of the Signal Service Bureau. By Charles Denison, A.M., M.D., Denver, Colorado.

UNUSUAL CASES OF VESICO-VAGINAL AND VESICO-UTERINE FISTULA.<sup>1</sup>

BY W. H. BAKER, M.D.

THE medical profession are so familiar with the appropriate treatment of vesico-vaginal fistula that a successful operation is now the rule, a failure the rare exception; nor is this most favorable result confined to a few operators of large experience, but, thanks to Sims, Emmet, Simon, and Bozeman, the principles involved in the preparation of the parts have been so clearly set forth, as well as the steps of the operation so carefully worked out in every detail, that any surgeon of ordinary manipulative skill and care has been able to appropriate it to the particular cases under his charge and obtain very satisfactory results. With this almost universal success attending the operation at the hands of the surgeon each is stimulated to excel if possible, either by gaining an equally good result so far as the closing of the fistula is concerned, and leaving the other organs and surrounding parts in a natural and healthy condition, or by diminishing to the minimum the amount of cicatricial tissue in the vagina, both of which he has found to be so necessary for the future comfort and health of his patient. The report then of ordinary cases of this class would seem to be quite unnecessary and would be of but little interest to the members of this society who give more especial attention to these and kindred complaints. If, however, cases arise which, from their cause, course, or method of treatment, differ from those we are accustomed to see, and thus become unusual, they are at once valuable. For any success which has attended my work in this class of cases, as well as many others, I am indebted to Dr. T. Addis Emmet, for whose faithfulness and kindness as an instructor I shall never cease to be grateful. In looking over the records of my hospital and private practice I find four cases which, from their somewhat unusual character, seem of sufficient importance to bring before this society.

## CASE I. VESICO-VAGINAL FISTULA WITH CLOSURE OF THE URETHRA.

August 14, 1879. I was called in consultation by a physician of this city, who gave me the following history of his patient: She was forty years of age, had been married about two years, and was delivered at full term of a still-born child three weeks before my visit, it being her first and only confinement. For a month before her labor the legs were swollen and an examination of the urine showed twenty-five per cent. of albumen present. The waters broke about midnight and the next morning the os was not at all dilated, but through the day it became so to the size of a half-dollar. About eight p.m. of that day one fluid drachm of ergot was given and during the next two hours four drachms more of the same were administered in teaspoonful doses. At ten p.m. the patient complained that she was unable to see; the child was then at the outlet, it having been steadily but slowly progressing. Another physician was then called in consultation, who at

once applied the forceps and delivered the patient of a child, who gave evidence of having been dead twenty-four hours. The attending physician was then informed by the patient that she had not passed much of any urine for two days before the labor: the catheter, however, showed very little urine in the bladder; but the next day and from that time on, there had not ceased to be a continual flow of urine by the vagina.

The left side of the face was paralyzed and the left side of body and left leg were wanting in sensation, though motion was not especially impaired.

On making a physical examination I found a vesico-vaginal fistula in the median line which readily admitted the forefinger, the anterior edge of which rent involved the neck of the bladder. The perineum had also been ruptured to the sphincter muscle. Diagram No. 1 will show the location of the injury.

Fig. 1.

Neither the general condition of the patient nor the local site of the injury were in any state to warrant an immediate operation, and she was advised to use a vaginal injection of carbolyzed warm water three times a day, and to keep the skin of the vulva, inner thighs, and nates well protected with oxide-of-zinc ointment or vaseline. I expressed a desire to see her again after two or three months.

November 20th. At the request of the attending physician I assumed the care of the case, and an examination then made showed the parts in good condition for closing the fistula, the opening being somewhat smaller than at the previous visit, barely admitting the tip of the forefinger. On exploring the urethra it was found that the upper part of the canal at the site of the neck of the bladder was entirely closed by a dense cicatrix. This was incised with a narrow bistoury, and a hard-rubber plug adjusted to keep it from closing again. The closure of the fistula was delayed for nearly two months more, or until the incised wound at the neck of the bladder had entirely healed and the patient's general health, which was fast improving, should be in as perfect a state as possible.

January 13, 1880. The hard rubber plug was removed and the edges of the fistula denuded and brought together in a line transversely in the vagina with eleven silver sutures. A Sims's self-retaining catheter was adjusted. For the next week the vaginal douche was used twice a day, at which times

<sup>1</sup> Read before the Obstetrical Society of Boston, December 13, 1881.

the bladder was washed out and the catheter thoroughly cleansed and replaced. The sutures were removed on the eighth day, and union found to be perfect.

February 10th. She reported perfect control over the urine except when holding it several hours. I have seen the patient within a few months, and she reports herself quite well and as having had no farther difficulty with the bladder.

The point of especial interest in the injury and its repair was that having cut through the dense cicatrix, which must have been nearly a quarter of an inch thick, there showed no tendency for its contraction again, and there has never been any evidence of the formation of any stricture at the site.

#### CASE II. VESICO-VAGINAL FISTULA WITH LOSS OF THE ANTERIOR LIP OF THE CERVIX UTERI.

Mrs. A. S. was admitted to the Free Hospital for Women on October 1, 1883. She was twenty-eight years of age, had been married seven years, and had given birth to six children, all still-born. Labors were all characterized as difficult, and terminated instrumentally. She had a fair getting up after each of her confinements except the last. Three weeks after the last labor she noticed a dribbling of the urine, and she had been thus constantly troubled ever since. She complained of nothing save this continual flow of urine. Her general health was excellent. An examination showed the external parts red, thickened, and excoriated from the irritation of the urine. The cervix uteri was torn bilaterally, the posterior lip everted and turned back into the posterior cul-de-sac, and the anterior lip entirely gone, it undoubtedly having separated with the slough which came away when the urine first passed by the vagina. The cicatrix had so drawn the upper anterior vaginal wall around the stump of the anterior portion of the supra-vaginal cervix that it was not until the posterior lip of the cervix was forcibly pushed toward the sacrum that the cervical canal could be brought into view. This turning of the uterine canal into the fistula was aggravated by the somewhat retroverted state of the uterus. The fistulous opening itself was about half an inch transversely; it was difficult to estimate its size antero-posteriorly, as it was so covered by the anterior vaginal wall (see diagram No. 2).

Fig. 2.

She was prepared for the operation in a similar manner to case I, that is, by the vaginal douche and

anointing with vaseline. The fistula was closed November 1, 1883, fourteen silver sutures being used. It required a considerable amount of patience to free the parts surrounding the fistula sufficiently to denude its edges, as the opening was held so completely out of view by the cicatricial bands all about it. When this was accomplished, it was found that there was not sufficient of the stump of the anterior lip of the cervix to denude, to which the anterior vaginal wall could be attached. The simplest and by far the easiest way would have been to turn the uterine canal into the bladder and attach the anterior edge of the fistula to the posterior lip of the cervix, but this would have necessitated the patient's subsequently menstruating into the bladder, and not only so, but the everted and lacerated posterior lip of the cervix in the bladder, unprotected by its normal vaginal covering, constantly exposed to the urine, would have almost inevitably given rise to increased disease and suffering. By strong traction, therefore, the uterus was brought sufficiently low to enable a portion of the posterior vesical wall above the stump of the anterior lip of the cervix to be denuded through the fistula to which the vaginal edge was attached.

November 7th. The patient was menstruating, therefore the removal of the sutures was delayed for five days, or until the twelfth of that month. The union in this case was perfect. She was allowed to pass the urine herself each two to four hours and the only unfavorable symptoms presenting themselves were the appearance of the menses before the expiration of a week from the date of the operation, which, however, fortunately did not impair the success of the operation, and the development of an attack of cystitis, which yielded to benzoate of ammonia and washing out of the bladder.

November 27th. The patient reported perfect control over the bladder and was discharged cured.

The specially interesting feature in the case was the fact that vesical tissue alone was denuded posteriorly, by which it became possible to close the fistula without turning the uterine canal into the bladder.

#### CASE III. VESICO-VAGINAL FISTULA OCCASIONED BY AN ILL-FITTING PESSARY.

Mrs. D. was admitted to the Free Hospital for Women, December 19, 1883, and gave the following history: She was a widow, forty years of age, and had had five children and two miscarriages. Her labors were, so far as she knew, natural. She had suffered for a long time with bearing-down pains, for which she had consulted a physician a year previous to her admission to the hospital, who told her she had prolapse of the womb, and introduced a Babcock pessary, which she wore for six weeks. During that time she suffered constant pain from it and so reported to her physician; but he refused to remove it, telling her she must become accustomed to it; when he was told, however, that the urine was running away through the vagina, he hastened to remove it.

While in the hospital it was noticed that the urine did not constantly dribble away, but escaped only at certain times or when in certain positions, for example, she was not obliged to wear a napkin and

had complete control over the bladder for three or four hours and could sleep all night in certain positions without the urine escaping, but on suddenly turning she would find herself wet.

Fig. 3.

A physical examination (see diagram No. 3) revealed a vesico-vaginal fistula, about three quarters of an inch in length, at the site of the attachment of the anterior vaginal wall to the cervix uteri. The uterus was in the first degree of retroversion, its lower segment lacerated bilaterally, and the everted anterior lip forced through the fistula into the bladder. This readily accounted for the ability of the patient to hold the urine under certain circumstances, for the opening was so effectually plugged by this portion of the cervix, that it was only when by some movements of the body the edges of the fistula were made to slide on the anterior lip that the valve would open sufficiently for the urine to flow.

After a week of preparatory treatment with the vaginal douche, the fistula was closed with nineteen silver sutures. Some difficulty was experienced at the time *c.* the operation in freeing the fistula sufficiently to allow the anterior lip being drawn back into the vagina from the bladder, where it appeared to be somewhat strangulated by the edges of the fistula which had contracted around its upper part.

On the fifth day after the operation the nurse noticed that the bed was wet and urine continued to dribble afterward. The sutures were removed on January 17th, or the eighth day after the operation; five of them had sloughed out, and were loose in the vagina; these stitches were at the right angle of the wound. Notwithstanding this unfavorable symptom, twenty-five days after the operation no fistulous opening could be found and the bladder filled with milk failed to show any escape into the vagina. The patient herself had noticed no moisture from the vagina for several days previously and she was thought to be cured. It was proved, however, in the succeeding month that she was not entirely relieved, and she entered the hospital again May 14, 1884, and a minute fistula was found at the right angle of the former wound which after denuding, was closed with five silver sutures. The result was perfect and she was discharged, cured, June 3, 1884.

The nearly complete plugging of the fistula by the anterior lip of the cervix, as well as the cause

of the fistula in this case, seem to make it noteworthy.

#### CASE IV. VESICO-UTERINE FISTULA.

Mrs. A. B. was brought to me on October 9, 1884, by a physician of this city, and gave the following history: She was fifty years of age, had been married thirty years, and had had ten children and two abortions. The menopause was established at forty-seven. Twenty-four years before, after a hard and tedious confinement, the head remaining impacted for a long time, she first noticed a dribbling of urine by the vagina, which continued afterward, requiring the use of ten or more napkins a day. The urine flowed away most freely when standing. She could at times retain about four ounces in the bladder and expel it through the urethra.

On examination the fistula could not be detected, and she was advised to enter St. Margaret's Home, and, when etherized, to perfect the examination, and on discovery of the fistula close it at once.

Fig. 4.

October 29th. Ether was given, and a small fistula found communicating with the cervical canal anteriorly about midway between the internal and external os uteri and the bladder. The uterine terminus of the fistula was so small that it barely admitted Emmet's probe, and it was with considerable difficulty that its opening could be discovered, on account of the atrophied state of the uterus, the small size of the os uteri externum, and the somewhat narrow vagina. The anterior lip of the cervix was cut through in the median line down to the fistula, which was then denuded and closed with five silver sutures, the innermost and uppermost suture being turned through the cervical canal and out of the os externum, the remaining stitches uniting the substance of the cervix as in an anterior laceration of the cervix. She had no unfavorable symptoms; four of the sutures were removed on the seventh day and the fifth or uppermost one was left for a month. Union was perfect and the relief complete.

The case is an interesting one, as illustrating the method of the establishment of this class of fistulas from an anterior laceration of the cervix uteri, and the possibility in such a labor of the tear extending beyond the cellular attachment of the bladder to the supra-vaginal cervix into the body of the uterus. It is also worthy of note that, although the urine was constantly flowing through the uterine canal, yet it did not prove a barrier to conception, as she

gave birth to several children after the establishment of the fistula.

In reviewing the cases reported I would remark that a departure was made in the first instance from the general rule which I follow of either allowing the patient to pass the urine after the operation or, if unable so to do, of having it drawn each two or four hours. This was done, as it was thought the patency of the urethra would be surely established by the self-retaining catheter.

The second and third cases showed the advantages of the method of freeing the parts at the time of the operation by cutting the cicatricial bands and thus exposing the fistula sufficiently to denude and close at once, instead of the more tedious way of gradually freeing it by traction and cutting a little at a time, occasioning the patient much more suffering.

In the way of suggestions, I would offer the following:—

First. That in performing this operation more than the usual number of stitches be used; that is, instead of passing five or six to the inch, put in ten or twelve, and then let the patient pass the urine herself, and if we can do without the use of the catheter we can reduce to the minimum the danger of cystitis.

Second. Watch carefully the condition of the urine, and on the first indication of an excess of mucous or ammoniacal odor, give benzoate of ammonia, and if, in spite of this, cystitis is established, frequently wash out the bladder with borated water.

I am indebted to both Drs. F. H. Davenport and J. W. Elliot for their assistance in the operations and subsequent care of three of the cases reported.

#### THE RECENT INVESTIGATIONS CONCERNING THE ETIOLOGY OF CHOLERA.<sup>1</sup>

BY R. R. FITZ, M.D.,

Professor of Pathology in Harvard University.

THE evidence against the constant presence of comma-bacilli in cholera may be said to have begun with the report of the French Commission. Although numerous microorganisms were found in the intestine, and some formed a sort of pure cultivation, there were none resembling the comma-bacillus of Koch. Its examinations of the blood and various organs with reference to the constant presence of any special form of bacillus were negative.

Lewis, in the article previously referred to, although finding comma-bacilli more or less conspicuously present in all of the numerous specimens of dejections from cholera patients in Marseilles, objected to their consideration as the *materies morbi*. His objection was based chiefly on the assumption that the comma-bacilli were identical with forms obtained from the mouth, and on the observation of additional, totally different, organisms in the intestinal discharges in cholera.

Cesi and Klebs report that comma-bacilli are not invariably present in the faeces of cholera patients or in the intestinal contents of the bodies of those

who have rapidly succumbed to the disease. It is obvious from what Koch has already communicated that, in doubtful cases, cultivations are necessary, owing to the small number of comma-bacilli present, and their frequent admixture with other organisms.

The Bavarian government sent Dr. Emmerich to Naples to make pure cultivations of Koch's comma-bacilli. From an abstract of the report of this investigator it appears that he was not content with finding a peculiar microorganism in the intestinal contents, and apparently nowhere else, in cases of cholera, but endeavored to discover specific organisms in the organs and tissues. Although he found comma-bacilli in the intestinal contents in certain instances, he laid greater stress upon the presence of a bacterium. This was obtained in cultivations from blood taken during life, and in others from the kidneys, liver, lungs, and spleen of nine persons who had died of cholera. The same bacterium was found in the dejections, in the intestinal contents after death, and in sections of the wall of the intestine.

Emmerich's paper is criticized sharply and at considerable length by Flüge, of Göttingen, who finds that his observations and experiments are not free from errors, and his conclusions not sufficiently justified.

Klein and Gibbes claim that comma-bacilli are found in epidemic diarrhoea, dysentery, and in the intestinal catarrh of phthisis, as well as in the intestines of cases of cholera. They did not find the comma-bacilli in such numbers and with such frequency in acute, typical cases of cholera as to justify Koch's statement that the ileum contains almost a pure cultivation of comma-bacilli. They deny the presence of comma-bacilli in the tissue of the intestine. They find straight bacilli in mucous flakes taken from the ileum of cases of acute cholera soon after death, even when comma-bacilli are not seen.

These adverse criticisms are controlled by the number of supporting observations, some of which are reported in such detail as to leave but little doubt of their value. Nicati and Rietsch were among the first to confirm Koch's views with regard to the presence of the comma-bacilli in the intestinal contents in cases of cholera. Van Ermengem's observations were alike confirmatory. Doyen examined the intestinal contents and viscera from cholera patients soon after death. The comma-bacillus was found in all cases, and as pure cultivations in the duodenum and upper part of the ileum in rapidly fatal cases. In those more protracted they were found mixed with bacteria in the ileum. He does not mention their presence in cultivations from the blood, liver, spleen, and kidneys, but finds other varieties of microorganisms.

Pfeiffer examined the stools of twelve cases of cholera, and found comma-bacilli in all. In three, rapidly ending in death, the intestinal contents at the post-mortem examination consisted chiefly of comma-bacilli. A microscopic examination of the intestinal wall in one instance showed comma-bacilli in the gland crypts. Controlling observations were made, but with negative results. In all but two cases of cholera out of fifteen examined by Babes comma-bacilli were found. In seven they were so

<sup>1</sup> Concluded from page 129

few and so mixed with other organisms that he could not form an absolute diagnosis with regard to their nature.

Cultivations from five protracted cases, lasting from six to ten days, gave negative results in two instances, although several plates were prepared from one of them. He never found comma-bacilli in intestinal contents except in cholera.

The weight of the evidence thus far recorded is distinctly confirmatory of Koch's claim of the constant presence of characteristic, well-defined micro-organisms in the intestinal contents of cases of cholera, and nowhere else except in direct connection with the latter. In his own words, "the comma-bacilli are specific bacteria found only in Asiatic cholera."

The question now arises for consideration as to the relation borne by the comma-bacilli to cholera.

It follows directly, if the above statement be regarded as proved, that, in the first place, they are to be regarded as diagnostic of Asiatic cholera. The importance of this discovery needs no elucidation. The possibility of recognizing the first case of cholera in any given community, no matter how slight or how abnormal its symptoms, is capable of proving of immense value in permitting appropriate measures to be taken to prevent the spread of the disease.

But Koch claims still more for his discovery: he regards it as proved that the comma-bacilli are the cause of cholera.

When this statement was made at the Berlin Conference he acknowledged the negative results of all his attempts at inoculating the disease in animals. It is needless to say that these were as numerous and as varied as possible. He felt obliged to come to the conclusion that the animals used, and others ordinarily in communication with man, have an immunity from cholera, there being no well-authenticated instances of cholera in animals. At the same time he considers the existing facts sufficient to justify the claim that the comma-bacilli are the essence of cholera. His argument is essentially as follows:—

(1) They are constantly present in the disease and nowhere else.

(2) They are always found in immense quantities, and usually as a pure culture on the linen deiled with dejections from cholera patients.

(3) It is generally admitted that the disease is often transmitted through the soiled linen, and when such transmission occurs the comma-bacilli are the only organisms in question.

(4) Their occurrence corresponds with the pathological changes in the body and the course of the disease.

(5) The entire aetiology of cholera is in harmony with the qualities of the comma-bacilli.

In explanation of the fourth proposition, it is stated that the comma-bacilli grow very rapidly, their vegetation soon reaching its height. With its cessation the comma-bacilli are finally overcome by other bacilli. These features in their growth exactly correspond with what takes place in the intestine in cholera. It is easily conceived that with the admission of even a single bacillus into the intestine a rapid increase may take place, which, when it

reaches a certain point, may occasion irritation and diarrhoea. When the progressive increase has reached its maximum the peculiar symptoms of the attacks of cholera may be considered as present.

The infection of individuals with soiled linen was regarded as equivalent to experimental proof of the production of cholera by inoculation with comma-bacilli. The tank affair, previously referred to, was regarded in the same light. When the epidemic was at its height the comma-bacilli were found in the water in tolerable abundance, and in many places along the tank. The abundance was such as to necessitate a multiplication. Later, when only solitary cases of cholera occurred, the bacilli were found only in one place and in small quantity. If the sick had furnished the bacilli, the latter should have been far more abundant at the second examination.

In reply to the argument, based on the above experience, Pettenkofer claims that for this observation to be of value comma-bacilli should have been found in the tank before the cholera made its appearance in the vicinity. It was natural that they should be found in the water after the foul linen was washed in the tank. Their disappearance with the cessation of the epidemic was a natural consequence of the fact that there were no more clothes from cholera patients to be washed.

Koch's attempts at producing in India a disease among animals resembling cholera were negative. Since his return, however, inoculations have been made, and are claimed to be successful. The assumption that the comma-bacilli are the immediate cause of cholera thus appears to have met with experimental proof. Nicati and Rietsch were the first to report favorable results from the inoculation of animals—dogs—with the bacilli of cholera. The intestinal contents from cholera patients or cultivations of cholera-bacilli were introduced into the duodenum. After one or more days the animals died. The symptoms occurring corresponded with those met with in acute and rapidly fatal cases of cholera in man. The intestinal contents consisted of a milk-like pap, rich in epithelium, and containing immense numbers of comma-bacilli. They resembled those of the intestine in acute and rapidly fatal cases of cholera in the human species. Where large quantities of virulent material were introduced into the stomach and duodenum of Guinea-pigs the comma-bacilli were developed.

Koch repeated these experiments, using scarcely the hundredth part of a drop of the product of cultivation. After its injection into the duodenum the animals died within three days. The mucous membrane of the small intestine was found to be reddened, the contents watery, flocculent, and either colorless or pale red. The comma-bacilli were found in the intestinal contents as a pure cultivation, and in extraordinary quantities. The appearances were such as are found in the intestines in recent cases of cholera. He considered that the possibility of a simultaneous poisoning from toxic material contained in the cultivation was eliminated by the small quantity of the infective fluid used.

Van Ermengen obtained satisfactory results from the inoculation with pure cultivations of dogs, rabbits, and Guinea-pigs. Three out of four Guinea-

pigs died within three days after the inoculation, and the results of the post-mortem examinations were like those in cholera.

Doyen also claims to have produced cholera in Guinea-pigs and dogs. A Guinea-pig inoculated from a cultivation by Babes died after three days, and the intestine showed the changes found in cholera.

The results of these inoculation-experiments show that the comma-bacilli possess decided pathogenic properties. Whether the disease thus produced in animals is to be regarded as cholera must still remain an open question. Pathogenic properties must also be claimed for the bacteria which Emmerich obtained from cases of cholera if they prove to be pure cultivations. He believes that the lesions, especially of the small intestine, resulting from his inoculations simulate those in persons who have died of cholera. The alterations are described as varying from a simple desquamative catarrh, with intestinal contents resembling rice-water, to hemorrhagic exudations and ulcerative destruction of the mucous coat. The larger the quantity used for inoculation the earlier the fatal termination, and the more protracted the course of the disease the greater the severity of the intestinal lesions.

In his criticism of Emmerich's report Flügge states that, although cholera-like conditions resulted from inoculations with some of the cultivations, the evidence is not sufficient to warrant the diagnosis of Asiatic cholera. He further maintains that the described alterations of the intestines are by no means rare after injection with fission-fungi, which have no relation to cholera.

The foregoing analysis, based essentially upon abstracts from the various authors referred to, seems to justify the following conclusions:—

(1) A well-defined characteristic organism—the comma-bacillus of Koch—is to be found in all cases of cholera, especially during the earlier stages of the disease. It is never found except in connection with cholera.

(2) It is present in such quantities and under such circumstances as to indicate that it has an important influence in producing the symptoms and spread of the disease.

(3) When introduced into the intestine of certain animals it occasions alterations of the intestine, especially of the small intestine and its contents, resembling in appearance and in composition those found in cholera.

(4) A thorough appreciation of the properties of this organism is, therefore, essential for the early recognition of suspected cases of cholera, and especially for intelligent attempts at preventing the origin and spread of the disease.

The growth of the comma-bacillus demands a moist medium, a certain temperature, and a suitable soil. Its transfer in an active state requires agencies other than the atmosphere, since dried bacilli are incapable of reproduction. The various observations and experiments show that the comma-bacillus is not only present in the discharges and on the soiled garments of the patient, but is also to be found in water which is drunk and which is employed for various household purposes. Among the latter are to be included its use in preparing

food, in cleaning dishes and various utensils, and for bathing purposes. Babes reports that the comma-bacillus is capable of retaining life for at least forty-eight hours on faeces, cheese, fresh vegetables, potatoes, fruit-juices, in sweetened water, chocolate, and coffee. It could be cultivated after remaining seven days in the water of the Seine and in that supplied through the Berlin aqueduct. The cultivations in gelatine and Japanese isinglass are capable of reproduction after a period of weeks and months. It grows upon various articles used as food, such as carrots, cabbage, boiled potatoes, pulse, fresh meat, boiled eggs, and in milk and broth.

The intestinal contents of the patient during the early part of his illness constantly offer favorable opportunities for the propagation of the bacillus. Abundant material outside his body serves both for the reproduction of the bacillus and for the preservation of its vitality for a long time. In the latter event the transfer to a suitable soil at once permits an active growth. These facts are sufficiently explanatory of the wide differences in the period of incubation of cholera, extending from two days to several weeks, twenty-four days in one instance being referred to by Eichhorst.

The effect of the various levels of the soil-water in the ætiology of cholera, to which Pettenkofer attaches so much importance, admits of a ready explanation in the light of Koch's researches. Provided that suitable nourishment is at hand in a damp soil, the lowering of the water-level favors stagnation and the concentration of nutriment. The bacilli have not been found in air exhaled from the lungs of patients, nor is it likely, in the light of the late researches, that atmospheric currents can transfer the contagium to any considerable extent, as claimed by Pettenkofer. Koch recognizes the possibility of the transmission of active bacilli by means of the air as an exceptional occurrence, but only for short distances, as in the vaporizing of contaminated water sprinkled in streets and inhaled into the mouth and swallowed.

The doctrine of individual predisposition, which also occupies a prominent position in the ætiology of cholera, is readily explained by Koch in accordance with his view that the comma-bacillus is the cause of the disease. It appeared from experiments on animals that under ordinary circumstances the vitality of the comma-bacillus is destroyed in the stomach. The individuals universally regarded as predisposed to cholera are those suffering from indigestion, gastric or intestinal. The rapid transfer of the contents of the stomach to the intestine, especially of masses of partly digested food, offers an easy passage of active bacilli to the alkaline fluids of the small intestine.

The action of the comma-bacillus in producing the symptoms of cholera is regarded by Koch as chiefly toxic in virtue of its assumed products. The history of various bacterial processes indicates that such a poison may be produced, and comma-bacilli are not found in the blood of patients or of animals who have been infected through the intestine. In rapidly fatal cases, with evidence of paralysis of the circulatory apparatus, but little fluid may be exuded from the vessels. In such instances death cannot be attributed to inspissation of the blood.

In a series of feeding experiments on swine by Dr. Richards, referred to by Koch, some of the animals fed with dejections from cases of cholera died within fifteen minutes; others within two and a half hours. So rapid a death was distinctly suggestive of a toxæmia. In the typhoid stage of cholera it is considered probable that the symptoms are in part determined by the absorption of the products of other bacteria, which are found in abundance in the putrid intestinal contents.

A CASE OF PELVIC ABSCESS FOLLOWING CHILD-BIRTH.<sup>1</sup>

BY E. J. FORSTER, M.D.

For the second time in the same house, at about the same season of the year, I delivered Mrs. X., after a short and natural labor. Two doses of chloral, three quarters of a grain each, were given half an hour apart. Everything progressed well until the morning of the third day, when the temperature was found to be 103.2° F.; this fell to 102° F. toward afternoon, and was attributed, erroneously as I now think, to mental worry. The evening of the fourth day the temperature was again 103° F. A local cause was then looked for and found in a slight laceration about the perineum; this was immediately touched with nitrate of silver, and the morning temperature was found to be 99° F., and the patient's condition in every way satisfactory. On the evening of the sixth day, the temperature being nearly 105° F., the lacerations about the perineum were dusted with iodoform. The next day the temperature was 102° F. in the morning, and reaching 105° F. in the evening, a vaginal examination was made and a laceration of the cervix found; this was wiped clean and thoroughly dusted with iodoform. The following day the temperature was normal in the morning, only reaching 99° F. at night. I thought that we should then have continued improvement; but instead the temperature gradually increased and the

general condition became less favorable, and on the tenth day I felt that an inter-uterine injection was indicated to eliminate any further source of poison. One was given, as I thought thoroughly; but I am convinced it was not, though I gave it myself; for the temperature rose the following night to 105° F., when the douche was carefully repeated and some shreds brought away, the temperature then falling to below 100° F. the next morning, and two days later reaching normal.

The general condition during this time was indicative of septicæmia: there were restlessness, diaphoresis, scanty supply of milk, slight show, the latter not offensive, owing no doubt to the vaginal douches and the applications of iodoform which were daily used. The general treatment consisted of quinine, and nourishment by milk, eggs, and alcohol in the form of punch.

The fifteenth day the amount of milk in the breast increased, and the temperature rose to 102° F. The next day the nurse was taken sick with a follicular tonsillitis, and the patient's temperature rose to 104° F. This sickness of the nurse and the increase in temperature led me to think that there might be some cause other than the patient's own discharges for the septicæmia. A careful examination of the plumbing and drainage was made and nothing was found amiss. I submit a plan of the rooms of the floor occupied

by the patient. The open fireplace (in which a fire was kept) and windows gave good ventilation, and the bathroom was sufficiently removed not to be looked upon with serious concern. On the twentieth day a slight induration was noticed in the anterior cul-de-sac, which a day later discharged a drop or two of pus, when opened by a small incision. On the twenty-second day the temperature for the fourth time reached normal, and a slight show appeared. On the twenty-fifth day a bulging of the posterior vaginal wall was detected, and some tenderness in the left inguinal region on deep pressure, and some dull pain on changing posture. This was the first that any abdominal pain was present, though daily sought for. On the twenty-seventh day fluctuation was clearly defined in the posterior cul-de-sac, and on the twenty-ninth, the patient being etherized, with Dr. Baker's assistance and coincidence as to the proper course to pursue, the presence of pus was demonstrated by the aspiration and a free incision made evacuating a full tencup of pus. The sac of the abscess was thoroughly washed out with a Davidson syringe. The washings were continued at first twice, then once, daily, for about two weeks, when the tip of the syringe could no longer be introduced. The only rise in temperature of moment after the operation was on the second day when the common nozzle of the syringe was found not to be long

<sup>1</sup> Read before the Obstetrical Society of Boston, December 14, 1891.

to side, the patient meanwhile moaning slightly. The radial pulse on the right side was very weak; that on the left was almost imperceptible—78 per minute. The left arm and leg were quite paralyzed so far as could be determined. There had been slight vomiting.

On palpation over the præcordia, the cause of the patient's puzzling condition was discovered. A knob of about the size of a large pea was felt adhering to the chest-wall in the situation of the apex-beat; and this object proved to be the head of a large steel shawl-pin, three and three-eighths inches long, which the patient had thrust into her chest in a direction inward and slightly upward and to a depth of two and three-quarters inches. The pin was at once withdrawn and stimulants were given; almost immediately the heart's action began to gain in force, the pulse becoming stronger and steadier; consciousness returned. For some time there was very urgent dyspnoea, and the patient complained of pain in the præcordia, but these symptoms disappeared within an hour. The paralysis of the left side vanished, the pulse became steady and stronger, and the patient fully recognized what went on around her. On the following day she complained of some pain at the situation of the puncture. Her recovery proceeded without interruption.

**II. Recovery after the Passage of a Ramrod through the Brain.** Dr. G. Fischer reports the following:<sup>6</sup>

Through the accidental discharge of a carbine while it was being unloaded, a young man of seventeen received the following injuries: the ramrod was driven into his back at the right<sup>6</sup> side of the fourth dorsal vertebra, passed along the chest cavity, up through the right side of the neck, entering the base of the skull and traversing the brain, and protruded thirty centimeters (eleven and three-quarters inches) above the top of the head on the left side. The ramrod thus passed through the sphenomaxillary fossa, then through the right half of the sphenoid bone. The left frontal lobe must have been penetrated by the missile. The length of the wound, from the fourth dorsal vertebra to the left frontal bone, was thirty-five centimeters (thirteen and three-quarters inches); the length of the ramrod was fifty centimeters (nineteen and five-eighths inches).

The first symptoms after the injury were those of concussion of the brain; while after removing the rod, four hours after the injury (to accomplish which blows with a hammer were necessary), symptoms of compression appeared, due probably to hæmorrhage within the cranium. There was transient loss of memory; and, from the fourth to the twelfth day, escape of cerebro-spinal fluid from the left nostril. Pus was discharged from the right ear on the seventeenth day. Six weeks after the injury, atrophy of the right optic nerve was detected. Other symptoms had then disappeared. The wound in the head had healed on the thirty-fourth day. Eleven months after the injury the man was in a healthy condition, with the exception of the atrophy of the optic nerve.

**III. Rapid Recovery after Wound of the Stomach and Protrusion of Viscera.** Dr. Tansini reports<sup>7</sup> that a peasant was admitted under his care in the hospital at Lodi, with a wound three and a half inches long in the left hypochondrium. Through the wound protruded the stomach, the transverse colon, and a large part of the great omentum. On the anterior surface of the stomach was a wound, an inch and a quarter long, through which the mucous membrane bulged so as to fill it. This wound was closed with catgut sutures. The displaced viscera were cleaned, the external wound was enlarged, and the organs were returned. The peritonæum was cleansed through the wound by introducing pledgets of carbolized gauze soaked in warm carbolized water. The wound was finally dressed antiseptically. No fever supervened. Convalescence was uninterrupted, and the patient was discharged, well, twenty-six days after his admission.

**IV. Resuscitation and Recovery after Apparent Death by Hanging.** Mr. Ernest W. White, senior assistant medical officer in the Kent Lunatic Asylum, details an extraordinary case of resuscitation as follows:<sup>8</sup> A woman, an inmate of the asylum, where she was under treatment for melancholia, after several attempts at suicide by drowning and strangulation, eluded her attendants one afternoon, and was found suspended by the neck from a ladder, by means of portions of her dress and under-clothing tied together. She was discovered and cut down eight minutes after she was last seen. In three minutes more the medical officer reached her and immediately began artificial respiration. At this time her condition was as follows: her eyes were prominent, the corneæ glassy, the pupils widely dilated and insensible to light, the conjunctivæ without reflex irritability. The lips were livid, the tongue was swollen, the skin was ashy pale and inelastic. There was an oblique depressed mark on the neck, most conspicuous on the left side. The small veins and capillaries of the surface were turgid, and the surface temperature was low. There was no radial or temporal pulse, and no definite beat of the heart was recognizable by the stethoscope. There was absolute cessation of all natural respiratory efforts, complete unconsciousness, total abolition of reflex action and of muscular contractility under galvanic stimulus. The urine and faeces had been passed during or immediately following the act of suspension.

Inspiration and expiration were artificially imitated about ten times in the minute, the chest being compressed with expiration. The lower extremities were raised, and manual centripetal friction was used. In ten minutes there was the feeblest possible effort at natural respiration—a single weak, spasmodic contraction of the diaphragm. Simultaneously occurred very distant, weak, reduplicated cardiac pulsations, detected by the stethoscope. During the next half-hour artificial respiration was continued till the breathing was fairly, though feebly, established; the skin began to lose its deathlike hue, and reflex action of the pharynx could be excited. Flagellation with wet towels was

now used with manifest benefit in stimulating the respiration. In about two hours a radial pulse was felt. After two hours and thirty-five minutes the woman was put to bed. Great restlessness and jactitation ensued with the renewal of the circulation in the extremities. The lungs threw off a great amount of extremely fetid organic matter, tabiting the whole ward. Consciousness did not return till the following morning. At this time the woman's pulse was 140; she was drowsy, and her mind was confused. There was no sign of pulmonary engorgement beyond some slight basie hypostasis. She complained of general rheumatic-like pains. Her subsequent progress to full recovery was continuous though slow. She declared that she recollected the impulse which led her to hang herself, and remembered the act of suspension; but from that time, for two days, her memory was wholly obliterated. Her mental convalescence began from the time of this suicidal attempt and its fortunate management by the asylum physicians.

### Therapeutic Memoranda.

#### COCAINE IN THE DILATATION OF URETHRIAL STRICTURES.

BY ROBERT E. DIXON, M.D.

DURING the past month I have used in three cases of stricture of the urethra a four per cent. solution of cocaine previous to inserting, for dilatation of the canal, Otis's conical sounds. Half a drachm of the solution was injected into the urethra from a subcutaneous syringe, with the needle removed, and was retained from five to ten minutes in the different cases. In none of the cases was the stricture contracted below a No. 28 sound, and the sounds were inserted to the full size of the canal, varying from a No. 32 to a No. 31 sound, with usually little or no pain. In two of the cases sounds had been used previously to the injection of the cocaine solution, and always with considerable pain and uneasiness. The sense of relief experienced by those who had had sounds introduced both with and without cocaine was greatly in favor of the employment of the drug.

Its cost (\$1.25 per drachm) is against its being freely used as gradual dilatation of the urethra is generally practised, especially when the stricture is contracted below a No. 26 or No. 27 sound; but in those cases where there is but slight contraction, and the introduction of sounds at one sitting is sufficient to dilate the canal to its full calibre, cocaine is very efficient, and in all probability will soon be frequently employed in the dilatation of slight urethral contractions.

— The friends of the Garfield Hospital in Washington have asked for an appropriation of \$45,000 from Congress to meet the running expenses of the hospital.

— We understand that *The Index Medicus* is to be continued under the same conditions as heretofore, under the auspices of the publishing house of Parke, Davis & Co.

### Reports of Societies.

#### MASSACHUSETTS MEDICAL SOCIETY

##### COUNCILORS' MEETING.

A STATED meeting of the Councilors was held at the Medical Library, Boston, on Wednesday, 4th inst.

The meeting was called to order at eleven A.M., by the President, Dr. C. D. HOMANS. Sixty-nine Councilors indicated their presence by signing the roll.

##### APPOINTMENT OF DELEGATES AND COMMITTEES.

On nomination by the Chair the following delegates to other State Medical Societies were appointed:—

*Maine:* Drs. J. E. Pratt, of Sandwich; T. R. Clement, of Centerville.

*New Hampshire:* Drs. C. C. Pike, of Peabody; C. C. Odlin, of Melrose.

*Rhode Island:* Drs. J. R. Bronson, of Attleboro'; B. D. Gifford, of Chatham.

*Connecticut:* Drs. G. W. Munsell, of Harwich; S. T. Davis, of Orleans.

*New Jersey:* Drs. G. W. Doane, of Hyannis; R. H. Fanne, of Sandwich.

Committees were appointed:—

*To Audit the Treasurer's Accounts:* Drs. J. O. Marble, I. H. Hazelton.

*To Examine the Library:* Drs. Z. B. Adams, A. H. Johnson.

*To Examine the By-laws of District Societies:* Drs. S. D. Presbrey, J. C. White, F. W. Chapin.

In accordance with the recommendation of the Committee on Medical Diplomas it was

*Resolved,* That the following Medical Schools be added to the list of Colleges whose degrees are recognized by the society:—

University of Berne, University of Zürich, Woman's Medical College of the New York Infirmary, Woman's Medical College of Pennsylvania, School of Medicine in Paris.

It was also voted that graduates of all foreign Regular Medical Schools which are under government supervision, and graduates of all foreign Regular Medical Schools not under government supervision, who have obtained a license to practise in any foreign country, shall be eligible for examination by the Censors.

In case any applicant for admission (possessing a foreign medical diploma) should not belong to either of these two classes, the Censors shall refer the degree held by the applicant to the Committee on Diplomas, for instruction.

The Committee appointed at the meeting in October last to consider if it be proper to take steps to change the Constitution and By-laws in regard to Boards of Censors reported, through its chairman, Dr. Hazelton, that it is not advisable to take action toward the establishment of a Central Board of Censors. The Committee further stated that it seems desirable to call the attention of the several Boards of Censors to the lack of uniformity in the methods of examination in the different Districts, and suggested that some agreement be brought

about between them; avoiding too great strictness on the one hand, and too great laxity on the other, and securing this advantage in a measure by regular standards.

DR. HARVEY called attention to the importance of taking immediate steps toward securing from the Legislature a law regulating the practice of medicine. DR. TOWNSEND, chairman of the Committee appointed at the annual meeting of the Society "to advise, and secure, if possible, from the State Legislature, an enactment to protect the people from ignorant and incompetent practitioners of medicine," stated that the Committee had already taken steps in the duty assigned to it. He expressed the hope that when a hearing should be given, the members of the Society by their presence and influence would assist the Committee. After animated discussion it was voted that a committee of five be appointed from the Council to aid the Society's Committee in its petition to the Legislature.

The following were appointed to constitute the committee: Drs. G. C. Shattuck, B. E. Cotting, G. H. Lyman, H. W. Williams, A. Hosmer.

## PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. M. GREEN, M.D., SECRETARY.

DECEMBER 13, 1884. The President, DR. C. ELLERY STEDMAN, in the chair.

### UNUSUAL CASES OF VESICO-VAGINAL AND VESICO-UTERINE FISTULA.

DR. W. H. BAKER read a paper on this subject.<sup>1</sup>

DR. COTTING thought that the name of Dr. George Hayward should be included with those mentioned by the reader as one whose efforts had done much to establish the operation. Hayward was the first to operate in this country, and that too after the operation had been abandoned abroad.

DR. BOARDMAN remarked that in his student days cases of vesico-vaginal fistula were of frequent occurrence, but of late years they are seldom seen.

DR. RICHARDSON said that he could recall having seen only two cases of vesico-vaginal fistula in the out-patient department of the Massachusetts General Hospital during the years of his service there; he thought the rarity of the lesion in recent times was due to an improved practice in obstetrics.

DR. BLAKE thought that there were as many cases of fistula now as formerly; but that now they were cured at the first operation and did not pass from one hospital or physician to another, and therefore the same case was not reported several times. He thought the relation of Hayward and Sims to the operation for the cure of vesico-vaginal fistula was analogous to that of Jackson and Morton to the discovery of the anæsthetic properties of ether. Hayward doubtless could claim priority; but it was Sims who had brought the operation into general notice, established its legitimacy, and made it popular with the profession.

DR. BAKER said he was aware that different operators prior to Sims had cured isolated cases;

but he thought great credit was due to the man who rediscovers and popularizes an operation. Sims with great zeal devoted a large part of his time for three or four years to nine patients and eventually cured them all; he studied his failures and thus patiently perfected the operation. Dr. Baker thought this lesion was of much less frequent occurrence than formerly: in the Free Hospital for Women he had met with only ten or twelve cases in ten years. This comparative infrequency was in his opinion due to an improved practice of obstetrics. Most cases of vesical fistula can now be cured: there are, however, exceptional cases in which there is a great loss of tissue which can be cured, if at all, only by several operations. He recalled one remarkable case in which a large part of the base of the bladder and nearly the whole of the urethro-vaginal septum had sloughed away: Emmet performed thirty operations on this patient, gaining a little each time, until finally a complete cure was effected.

DR. E. J. FORSTER reported a case of

### PELVIC ABSCESS FOLLOWING CHILD-BIRTH.<sup>2</sup>

DR. BAKER said that he first aspired the effusion to establish the diagnosis; then, using the aspirating needle as a director, he opened the abscess with a long, narrow-bladed bistoury sufficiently to admit the finger. He thought this method superior to the use of trocars, as they were too large to be wielded with equal delicacy.

DR. CURTIS remarked that one peculiarity in deep-seated abscesses was the great variation in temperature without special reference to treatment: the temperature would often vary from 99° to a very high degree, was sometimes low at night and several degrees higher in the morning.

DR. BLAKE did not think that these great fluctuations of temperature in post-partum cases were necessarily of much import; but a continuous high temperature was significant. More attention had been given of late years to the diagnosis of this affection, and cases which formerly were called inflammation of the bowels were now known to be pelvic peritonitis or pelvic cellulitis. Regarding the treatment of pelvic abscess Dr. Blake believed in evacuating pus with trocar and bistoury and in subsequent washing and draining of the cavity, rather than in waiting for spontaneous opening which might take place into the bladder or rectum. Dr. Blake further observed that pelvic abscess after labor does not necessarily prevent subsequent pregnancies, that is, the Fallopian tubes are not necessarily occluded; but after non-puerperal cases pregnancy is not likely to occur.

DR. DOB alluded to a case in the City Hospital of a deep-seated abscess in the inguinal region, occurring after a first labor, which was instrumental: the patient was sick three months, but ultimately recovered, and has since been twice delivered.

DR. SINCLAIR said that subsequent fecundity in such cases is influenced by circumstances and depends on the situation of the abscess: he had known abortion to follow pelvic abscess several times before finally the patient came to labor at term. He thought that pelvic peritonitis followed or accompanied by abscess was one of the most

<sup>1</sup> See page 193.

<sup>2</sup> See page 126.

difficult cases to manage; but he believed in the expectant treatment, as it was hard to locate the pus and to know where to open: in this opinion, however, he believed he stood nearly alone in the society.

DR. REYNOLDS said: Pelvic abscess, occurring in the course of puerperal disease, is a comparatively rare event. We should bear in mind the truly conservative effort which it implies. The results may be exceedingly grave; but the fact of the limiting of the pus by the walls of the abscess in itself makes recovery possible, at times through judicious surgical interference, at times by the escape of the offending material through some natural outlet. Two remarkable cases illustrating this fact come to mind. I saw repeatedly some years since in a neighboring town a primipara, who had been many days under most thoroughly skilful hands, but whose temperature, pulse, and general condition continued to give the greatest cause for alarm. Clear evidence that pus existed could not be gained; but with rare judgment and skill Dr. W. H. Baker aspirated deeply, through the abdominal walls, a doubtful spot at the right lateral border of the uterus, and withdrew perhaps two drachms of fetid pus: the threatening symptoms subsided at once, and there was no further interference. The patient made a good, though slow, recovery.

About four years ago, a young and strong primipara, eclamptic, was with much difficulty delivered by forceps at term of a male child, dead. During the second week of the lying-in she became very ill, with a rapid pulse and high temperature, and she remained in that condition for many days. Pus was at intervals discharged from the vagina. In order to secure the best opportunity for the frequent use of the intra-uterine douche Dr. Baker introduced for me a hard-rubber drainage-tube into the uterine cavity and secured it in position. It was noticed that no pus followed the douche when given through this opening, though at other moments a free discharge came. I had conceived an impression that a passage had been formed through the uterine wall on the right side, and I was fortunate enough to introduce at that point a long hard-rubber nozzle, slightly curved toward the end; to my amazement this instrument, eleven inches in length, buried itself completely in the patient's body. Through it the abscess was most effectually washed out many times with carbolyzed injections. During the conduct of this case I had fortunately the presence and counsel of both Dr. W. L. Richardson and Dr. Baker. Dr. Baker agreed with me as to the course which my instrument pursued; but Dr. Richardson was not convinced that the tube had at any time entered the uterine cavity. Careful examination after convalescence showed the exact fact: at the right commissure of the uterine lips the wall had been torn through quite up to the internal os; the curved point of the instrument, reaching the angle at the top of this cleft, had passed out to the right and buried itself far up in the mother's abdomen. When a suitable time had elapsed the lacerated cervix was repaired under Dr. Baker's hand, though the depth of the tear made the operation unusually trying. No fixation of the uterus was ultimately left. The perineal body had

been deeply ruptured, the rent extending to the edge of the sphincter: complete restoration of the perineum was obtained. After a considerable interval pregnancy occurred, and a male child was safely delivered at term without accident. I have lately attended this patient in a third labor, when she gave birth to a large boy: the perineum remained unharmed. During the last lying-in some obscure sensitiveness presented itself at the site of the old abscess; but there was no other trace of the former injuries.

#### OBSERVATIONS ON THE CERVIX UTERI.

DR. HOSMER spoke as follows: The first observation which I report was made in the case of a young married woman, who aborted at the end of the third month in her third pregnancy. In neither of the previous labors, both at term, was anything discovered which bore any resemblance to the unusual condition that was found to exist at the time of the miscarriage. I reached the patient just as the contents of the uterus were passing into the vagina. I at once removed the ovum, and in doing so detected an elongation of the cervix such as I have before met with at that stage of pregnancy. In strong contrast with the firm and solid substance of the uterine body, and depending from it into the vagina, was the cervix in the form of a cylinder, fully twenty-five mm. in length; its lower extremity presenting an edge perfectly even and unbroken in its continuity; and its wall everywhere soft and flexible, with an estimated thickness of between two and three millimeters.

The second observation was made upon the body of a female fetus that was removed at an autopsy made in aid of a medical examination. In this case the pregnancy was supposed to have passed somewhat the seventh lunar month, the length of the child being 37 cm., and its weight 1,070 grams. On inspection of the genital organs the following condition was found: The length of the vagina was 30 mm., that is, eight per cent. of the whole length of the child. The uterine cervix projected into the vagina five mm., and to this fact I would call your attention with emphasis. The interior of the uterus was exposed by a section made through its anterior wall, and after the specimen had been immersed in alcohol for a short time the distinction between the body and the neck was very plainly marked, and the ratio of the latter to the former, in the matter of length, was as three to seven. The relatively large development of the inferior portion of the organ was a striking feature.

These observations possess a very great interest by reason of their relation to a condition which I long since described to this society, when I called its attention to that form of dystocia originating in tonic spasm of the internal os; and to make this relation, or rather resemblance, as conspicuous as possible I would in the shortest possible statement set forth three things: the excessive elongation of the cervix which is sometimes found in labors at term; the unusual development of the cervix noticed in the case of abortion, which was the subject of the first observation just now reported; the anatomy of the fetal uterus, as illustrated by the single case which I have described.

## APPARATUS FOR WASHING OUT THE BLADDER.

Dr. HOSMER exhibited an apparatus which he had designed to obviate the disadvantages of the double catheter and to facilitate the process of washing out the bladder. The difficulties and unsatisfactory results which attend the use of the double catheter are well known. In practice it constantly refuses to perform the reasonable duty assigned to it by the theory and construction of the instrument.

The wood-cut represents the apparatus in actual size: it is essentially a T, with a short body and two arms of unequal length. By means of the screw at D, it can be affixed to a (No. 1) Davidson syringe, in place of the nozzle. The arm C is intended to receive a piece, sixteen inches long, of 3-16 inch rubber tubing. The long conical tip, B A, is to be inserted into a catheter, the calibre of which may vary considerably.

The method of using is as follows: Place in the bladder a catheter as *large* as possible; make the connections already described, and carry the suction-pipe of the syringe to the bottom of a good-sized bottle containing the liquid to be used. Work the bulb until fluid escapes from the free end of the rubber tube; then, with a thumb and forefinger, compress the tube near the point C. By this manœuvre the liquid coming from the syringe is forced into the bladder. Continue to inject, *slowly*, until the patient experiences a feeling of slight distention; then remove the pressure from the rubber tube, and allow the bladder to empty itself. This alternating process must be repeated as often as is deemed necessary for the particular case.

For the male bladder the soft-rubber catheter is the best one, and may be fastened to the T before its introduction. For the female, preference is to be given to the gum-elastic catheter, reduced somewhat in its length.

The method here described offers all the advantage which accrues from the use of a catheter of large capacity. It also accomplishes perfectly the twofold object sought by the practice of washing out the bladder: first, to remove entirely that which is, or may become, foreign material; second, to unfold the diseased mucous membrane, and give it the full benefit of the direct application of a remedial agent.

In addition to these uses the new method furnishes the means of ascertaining, with a good deal of accuracy, the quantity of liquid which the bladder will receive, and the tension to which it may be subjected without serious discomfort. The former can be determined by the number of times the bulb of the syringe is compressed and emptied; and the latter by the degree of pressure that is felt between the thumb and finger which control the efferent current.

Dr. HOSMER alluded to a procedure which he had

found useful in relieving speedily the pain, sometimes serious, which is felt in certain cases of cystitis, as soon as the urine is evacuated: it is to throw into the empty bladder a small quantity (a tablespoonful) of infusion of slippery-elm bark, to which has been added from ten to twenty drops of laudanum. In one case, in the latter stage of convalescence, for the opium Dr. Hosmer substituted carbolic acid in very small proportion, and with very satisfactory results.

## THE USE OF ETHER IN PUERPERAL ECLAMPSIA.

Dr. REYNOLDS said: In accordance with an opinion which has been heretofore advanced by some of our members, I am strongly inclined to believe that in eclampsia continuous administration of ether will wholly prevent the recurrence of paroxysms. At any rate it is thought best to challenge from time to time the production of reliable evidence to the contrary. Ether thus employed should be given only by a physician. It must be so administered as to forbid any consciousness of discomfort or pain and to prevent restlessness. At the slightest indication of an approaching paroxysm it ought to be promptly carried to the surgical degree. The following case is briefly reported for its bearing upon these points:—

A woman, thirty-three years old, V-para, and supposing herself almost at term, had suffered in her first pregnancy severe eclampsia; then necessitating, at six and a half months, the induction of labor. On the present occasion she had been under medical observation. The urine, twice examined, was normal; its quantity continued abundant to the last. Nothing indicated danger. Her unusual health and spirits led her to make very imprudent exertions. There came a day of intense localized headache, with vomiting. I was called at evening. Ten minutes after my arrival she had a well-characterized eclamptic seizure. There was no evidence of labor. The os was soft and easily admitted the forefinger, the cranium presenting. As soon as ether could be procured she was put fully under its influence, Dr. C. M. Green and Dr. R. A. Kingman kindly giving me aid. The conditions were unusually favorable for prompt delivery. After rapid manual dilatation a foot was reached, and in fifteen minutes a small living male was born, apparently eight months advanced. The uterus contracted well. There was no hemorrhage. I remained with the patient till half-past twelve o'clock, frequently giving her ether for relief of pain. I then left her in charge of Dr. Kingman, who kindly offered to watch her. She slept. Ether was discontinued. At length the patient moved and stirred. Dr. Kingman decided to give her a solution of bromide and chloral, which was at hand, and for a moment he left the room to obtain it. A second convulsion of great severity occurred, there was extreme livor of the face, and the tongue was badly bitten. I was at once recalled, and from that hour till half-past ten in the forenoon following I stayed with her, etherizing her most of the time. When in health, Mrs. L. habitually snored in her sleep. One could not decide during these hours whether the labored breathing was the result of the convulsion, was due to the ether, or was

mainly the habit of the woman. Between five o'clock and half-past six the sleep became tranquil, and at that time no ether was given. At ten in the forenoon the temperature was normal, the pulse eighty, the intelligence perfect. Both mother and child did well. Just before the delivery, not less than six ounces of urine were found in the bladder, after an interval of eight hours. The urine was again removed at ten in the morning of the next day. Each of these specimens was carefully examined. The earlier one contained a few hyaline and finely granular casts. Four fifths of the mass formed a coagulum. The next time the amount of coagulum was reduced to one third of the whole. On the sixth day the specimen was normal; no cast could be found by most careful search. There was a bare trace of albumen.

I express my conviction that ether, given instantaneously, would have prevented the second convulsion; and that the tranquillity and opportunity for sleep which its subsequent administration secured to the patient largely influenced the prompt recovery. Under these conditions moderate anaesthesia may be safely kept up for a great number of hours.

This report, if relied on as proof of the foregoing statements, is evidently open to sharp criticism. It is rather presented as a challenge to bring out opposing facts, if such evidence can be produced.

#### PATHOLOGICAL SOCIETY OF PHILADELPHIA.

THURSDAY EVENING, JANUARY 8, 1885. The President, DR. SHAKESPEARE, in the chair.

DR. SHAKESPEARE presented the following specimens:—

PRIMARY TUMOR OF THE LIVER IN A CHILD NINE MONTHS OLD.—AORTIC VALVULAR DISEASE, WITH RUPTURE OF ONE OF THE LEAFLETS.—MALIGNANT TUMOR OF THE KIDNEY.—A LARGE RENAL CYST.

The notes of the above cases are withheld for future publication.

#### SARCOMA OF THE CLAVICLE.

Presented by DR. G. E. DE SCHWEINITZ.

This specimen was sent to me by Dr. John Ashhurst for microscopic examination, and he kindly gives me permission to exhibit it to-night. The tumor occurred in the person of a young girl, S. L. B., aged sixteen, who came to him for treatment last August. She was a somewhat frail-looking, clear-skinned blonde, whose general health up to the time of the appearance of the growth had been satisfactory. The family history was good; none of the other five children composing the family presented any similar affection, nor was there any history of tumor for two generations back. The tumor began at the left sterno-clavicular joint as a small nut-shaped swelling, having arisen without known inflammatory or traumatic origin, although, as the father stated, they always believed that the patient had, in some way unknown to herself, received an injury at this point. The growth of the tumor was rapid, and at the end of five months stood out as a prominent swelling, as large as an orange, occu-

pying the inner two thirds of the clavicle, and was covered by somewhat reddened and thinned skin. Pain, although not constant, was at times a very severe symptom. On the seventh of last August Professor Ashhurst removed the growth, together with the inner two thirds or three fourths of the clavicle. Examination of the gross specimen shows it to be a spindle-shaped growth, about four inches long, three inches at its greatest breadth, and two inches deep, which has taken its origin in the medullary cavity of the bone, gradually, and become surrounded by a firm fibrous or periosteous capsule. The true tumor tissue is of moderate consistence and a reddish-brown color. Microscopic examination reveals the following points of interest: The capsule is composed of dense fibrous tissue, from which prolongations pass, dividing the tumor into numerous spaces, which are filled with small, round sarcoma cells. These spaces are in many places again divided by a delicate spindle-shaped tissue into small alveoli. In addition to the round cells, spindle-shaped cells are also seen in spots; giant cells are absent, or at least only a few multinucleated cells, relegated to the regions of the spindle cells are noted. The tumor, I think, should be classified as a small round-celled sarcoma, with an alveolar arrangement. If this tumor be accepted as a variety of alveolar sarcoma, it is somewhat unusual. Twice before this evening specimens of alveolar sarcomata of the long bones have been exhibited to this society: one of the femur by Dr. Nancrede, and one of the knee-joint by Dr. Formad. At that time Dr. Formad thought the variety of the sarcoma justified a rather more favorable prognosis than usual, while Dr. S. W. Gross, during the discussion, after referring to the somewhat unusual microscopic character of the tumor, thought the outlook for the patient was bad, as this variety of sarcoma is peculiarly fatal. Dr. Formad's prognosis was correct, because in that instance the patient was alive and well, if I am not mistaken, for some time after the operation, and may be now for aught I know. In regard to the result in the present case, I am able to speak quite definitely. Although the operation was most successful and the removal of the growth quite complete, the hemorrhage insignificant, and the recovery of the patient satisfactory, in about two months after the operation the growth reappeared, either in the old wound or about two ribs lower. In this case, then, the truth of Dr. S. W. Gross's remarks has been only too thoroughly proved.

DR. SHAKESPEARE said that this specimen was of interest on account of the rarity with which similar ones had been presented to this society. Through the kindness of Dr. de Schweinitz he had the opportunity of examining sections from the growth, and thoroughly agreed with the exhibitor as to its nature.

DR. SIMES had also examined microscopic sections, and endorsed the statements made by the preceding speaker.

#### ALVEOLAR SARCOMA OF THE KIDNEY.

Presented by DR. M. LONGSTRECH.

The patient, J. E., aged nine months, was first under the care of Dr. McOscar, to whom I am

indebted for the specimens and this history, suffering from an attack of summer complaint. The patient was at that time three months old, and had been ill for a week or two. He was in a state of great emaciation, and upon examination of the abdomen a swelling was found in the right flank. The little patient recovered from the bowel trouble, but the general condition did not materially improve. During the remaining six months of life the child was only occasionally under observation, and at those times suffered from paroxysms of pain, apparently in connection with the tumor. The bulk of the tumor, as felt through the abdominal wall, did not seem to increase greatly up to his death. The urine was not carefully inspected. Three days before death the pain increased to great violence, and in this condition death came. The post-mortem examination showed the enlarged right kidney more firmly adherent to the posterior abdominal wall, and to the ascending colon and mesentery, as well as portions of the small intestine attached to its anterior surface. The diseased organ weighed fifty-two ounces, and presented itself as a rounded, slightly oval mass, regular in outline, smooth of surface, and with a moderately firm, elastic consistence. The capsular surface was of pretty dense, shining whiteness, with conspicuous small vessels passing over it. The section measured three and one-half inches by three inches in the two diameters; the tissue presented a very varied appearance. In parts it was of a dense white, perfectly homogeneous aspect; in others the pinkish-white mass showed streaks of yellow, with numerous small spots of red, and there were also large blood-red areas. In other parts the tissue was breaking down into cysts, of which several large ones were present, the largest of the size of an English walnut. The cysts were all situated on the periphery of the mass, but they did not cause any protrusion of the capsule. At the upper extremity of the mass there was found a portion of kidney tissue not invaded by the new formation. On section this portion occupied about half an inch of the long diameter of the mass, and was seen to be separated from the new growth by a thin partition of connective tissue; externally it showed itself like a lobe of kidney, fitting like a cap on the spherical tumor, as does the supra-renal capsule on the kidney itself. The microscopical examination showed the new formation to be a small, round-celled sarcoma. The greater portion of all sections presented cells nearly rounded in figure, imbedded in a perfectly homogeneous basis substance. The uniform area of cells was, however, interrupted by streaks of spindle cells running in narrow bands, inclosing greater or less areas of round-cell tissue. These circumscribed bands of spindle cells sometimes formed circular areas looking like the cross-section of a tube; in other places the bands pursued a very tortuous course, resembling the outline of a twisting, undulating tube cut in a longitudinal direction. The bands of spindle cells were never of great breadth, rarely more than four or five spindles. The spindle cells were not regularly or closely fitted, but were imbedded, like the round-cell elements, in a homogeneous basis substance. In the spindle-cell bands there were occasionally seen fine capillaries

filled with red blood corpuscles, which sometimes ran along for a considerable length; many other capillaries were seen cut transversely or obliquely; also in the spindle-cell tissue. Many areas of hemorrhage were visible. In many places a scanty fibrillar tissue, with various shaped nuclei, oval, angular, and spindle, was seen. This tissue was thrust in and filled the interstices between the areas of round cells, circumscribed by the spindle-cell tissue. Thus, in the section one passed from areas of round cells to the narrow bands of circumscribing spindles, and then into fibrillar tissue, with open meshes, apparently without any intercellular basis substance. The whole picture resembled the cortical portion of the kidney transformed by the presence of a new growth; the lumen of the convoluted tubes, greatly enlarged, was filled with a round-celled, homogeneous basis-substance tissue; the base membrane of tubes transformed into spindle-cell bands, and finally areas of hyperplastic intertubular connective tissue, in which or along the basement membrane of the tubes (spindle-cell bands) ran the intertubular capillaries. The left kidney weighed five ounces. On section it presented a normal aspect; the capsule separated easily, was not thickened, and the surface of the kidney remained smooth. The microscope showed no alteration of its tissues. The liver was large, smooth, blunt-edged, pale; under the microscope a very high degree of fatty infiltration was found. The other organs showed nothing especial to note. No secondary new formations were found.

### Recent Literature.

#### *A Practical Treatise on Fractures and Dislocations.*

By FRANK HASTINGS HAMILTON, A.B., A.M., M.D., LL.D. Philadelphia: Henry C. Lea's Son & Co. 1884.

Dr. Hamilton's Treatise is too well known to need extended comment upon the appearance of this its seventh edition. A considerable amount of new material has been added, and this, embodying as it does the results of recent observations and experiments, adds greatly to the already approved worth of the work.

#### *A Practical Treatise on Massage: Its History, Mode of Application, and Effects, etc.* By DOUGLAS GRAHAM, M.D., Fellow of the Massachusetts Medical Society. New York: Wm. Wood & Co. Pp. 280.

Dr. Graham's book calls attention to an important and rather neglected subject. There is no question that in "massage" — taking the word in its broadest possible sense, so as to make it include every form of physical exercise for the sick — we have to do with an agent that deserves the respectful attention of physicians. Some of the "irregulars" are better aware of this than we, and the result is that every now and then we are obliged to submit to the mortification of seeing our patients stray off to "respiratory cures" and the like, and return to us benefited and triumphant. Yet of medical men at large how many are there, even

among those who are in the habit of recommending massage, who have really devoted the same amount of study to its action that they have given to a single important drug in the pharmacopœia? Fortunately, this state of things is steadily passing away, and just as surgeons are ceasing to turn over their patients with club-foot or Pott's disease to the mercy of a surgical instrument maker, so physicians will not long continue to "try massage" without knowing just what it is that they are about to try.

Dr. Graham's book aims at collecting the scattered literature of this subject and incorporating with it the results of his own experience. He has certainly succeeded in making an interesting and evidently conscientious statement of what is known about the subject, and one which covers, so far as we know, almost the whole ground.

The mode of applying the different kinds of manipulation to the various parts of the body is clearly described; and the teachings of modern physiology are thoroughly utilized—even overutilized in one or two respects—to explain their mode of action. A long series of citations and personal observations illustrate the practical utility of massage in a great variety of diseases, such as nervous debility, uterine disorders, atony and other affections of the intestinal tract, paralysis, neuralgia, muscular rheumatism, sprains, diseases of the eyes, and catarrhal inflammations of the respiratory tract.

Notwithstanding the large and valuable amount of information which the author places at our disposal, and the fluency of his descriptions, the book has certain blemishes, not of fundamental importance to be sure, but which will often cause it to be read with impatience or thrown aside unfinished, even by some of those who are really interested in the subject-matter. There are too many jokes for a serious work, and too many irrelevant general remarks, especially in the clinical portion, for a critical monograph. Thus we judge the paragraphs given to the history of the Aryans (page 16) and to the question of the suitability of the "rest cure" for melancholia (page 111), and similar excursions. Poetical headings to each chapter impress us unpleasantly, as saying of a desire (which we well know was not present) of making the book appeal to two sets of readers. The style is fluent, but too diffuse.

The writer is conscientious and fair in his manner of quoting the experience of others, as, for example, with relation to uterine and ocular diseases, but we think that even an excess of caution and of critical spirit could advantageously have been shown in this respect. Massage of the uterus especially is so distinctly a treatment for gynecologists to judge of, and to apply, that the discussion of it might have been advantageously curtailed. As a whole the book is interesting and valuable, but we should like it better if the writer had contented himself with a forcible and critical presentation of the evidence showing to what extent, and in what manner, massage acts on the different tissues and organs of the body, and using the clinical data, so far as possible, to illustrate the physiological action of the treatment, and to point out rather the morbid conditions than the diseases in which it is useful, but leaving it mainly to his readers to draw their own thera-

peutic conclusions. Of course, there are some diseases, such as neuralgia and constipation, where we cannot wholly explain the *modus operandi* of such a remedy, but must content ourselves with recognizing its practical utility. In fine, we recommend the book cordially to our readers. There are many typographical errors, but the writer, in his preface, explains the reason for their presence.

*Surgical Delusions and Follies.* By JOHN B. ROBERTS, A.M., M.D. Philadelphia: P. Blakiston, Son & Co. 1884.

Dr. Roberts deals with many delusions held rather by the laity and some physicians than by professed surgeons. Many of the points he makes are however excellent, and might well be considered by practising and hospital surgeons. He justly condemns the habitual use of sponges, and points out the advantages of clean linen and towels, or of absorbent paper for the cleansing of wounds during operation. His recommendation of always incising the scalp over a simple fracture of the skull before the appearance of symptoms of compression or irritation, "whenever there is the least suspicion as to the existence of depression or splintering," cannot be regarded as wise. What surgeon is so sure of obtaining antiseptic conditions over the hairy scalp as to willingly convert a simple fracture of the skull into a compound one, without very strong presumptive evidence of the necessity of interference. It would be hard to say, whether the folly is most conspicuous in the overconservative or in the overbold treatment of these cases.

*Women, Plumbers, and Doctors; or, Household Sanitation.* By MRS. H. M. PLUNKETT. New York: D. Appleton & Co. Pp. 248. 1885.

Mrs. Plunkett's book is a valuable addition to the rapidly increasing list of popular works on household and personal hygiene. The author has treated the subject with the evident object, as expressed in the preface, of arousing the interest and practical efforts of a new class—the women: to whom the volume may safely be commended as a satisfactory illustration of the comment on page 10, that "women can rise above the beaten paths of cookery and needlework to some purpose." The book is supplied with copious illustrations. The chapters on the house-cellar, the water-supply, sewerage, and overlooked channels of infection, are especially commendable.

In view of the recent action, or rather inaction, of Congress in regard to the united appeal of the representatives of State Boards of Health from all parts of the Union, the comments on page 228, entitled "Wanted, an Epidemic," beginning as follows, are especially timely:—

"The only thing that scourges Congress up to any worthy action is an epidemic, either in progress or threatening; so that, while other nations are inaugurating broad and wise and statesmanlike measures, our government stands in the attitude of the typical bad boy who is 'good' just as long as the impending switch is in sight, but returns to his evil ways directly it is laid away."

It appears that not even the "impending switch" has had the desired effect upon the present session.

## Medical and Surgical Journal.

THURSDAY, FEBRUARY 26, 1885.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by CUPPLES, UPHAM & CO., Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.

CUPPLES, UPHAM AND COMPANY,  
283 WASHINGTON STREET, BOSTON, MASS.

## THE RUPTURE OF VEINS.

THE accidental rupture of a superficial varicose vein is an accident of so frequent occurrence that few practitioners of long standing have failed to meet with an example. The rupture of internal veins of any size, in the absence of serious accidental injury of neighboring parts, is of so infrequent occurrence that few practitioners have ever thought of its possibility. The rupture of an artery giving rise to traumatic aneurism is a well recognized accident, but there are many reasons why the veins should escape similar injuries. The fact that veins are liable to rupture, and that a ruptured vein may behave like a ruptured artery, causing an affection analogous to that named traumatic false aneurism and requiring similar treatment for its relief, is set forth in an article by Dr. Henry B. Sands, in the December (and, we regret to say, the final) issue of *The Archives of Medicine*. That the accident deserves special consideration, by and for itself, Dr. Sands has well shown. That the subject is scarcely alluded to in systematic surgery is sufficient excuse, if excuse is necessary, for drawing attention to the matter here.

The case which drew Dr. Sands's attention to the subject was briefly as follows: A gentleman, fifty-one years of age, while walking in the street was suddenly seized with a sharp pain in the left thigh so severe as to compel him to return home in a carriage. On the following day slight swelling of the thigh was noticed, and three or four days later ecchymosis of the upper and anterior portion of the thigh and of the scrotum. Continued pain, increasing swelling, and extensive discoloration marked the progress of the case for the next two months. No positive diagnosis was reached. It was imagined to be scorbutic; it was suspected to be a traumatic aneurism. Two months after the attack the swelling occupied the inner and posterior portions of the upper two thirds of the thigh, the affected limb being six inches greater than its fellow. The skin covering the tumor was stained in various hues by blood which had evidently come from a deep-seated extravasation. Much of the swelling was indurated, but fluctuation was well

marked at its lower and inner part. At first sight it seemed to pulsate, but careful examination showed that the pulsation was limited to the femoral artery, which could be seen and felt beating from Scarpa's space as far down as the lower end of Hunter's canal, which had apparently become superficial in consequence of a displacement of the sartorius muscle from the pressure of the swelling beneath it. The tension of the tumor was only moderate, but the patient alleged that at times it had been very great: an item of the history which attracted little attention, but which was subsequently shown to be of great importance. No thrill or murmur could be detected, nor did compression cause reduction in its bulk. Pulsation could be felt in the arteries below the tumor. A hyperdermic syringe withdrew dark-colored semi-fluid blood but no pus. The effusion was recognized as coming from a vein, and absorption was still hoped for; but seventeen days later, suppuration being again suspected and some indications of septic poisoning appearing, it was decided to lay the tumor open by free incision; but during the administration of ether it suddenly grew large and became exceedingly firm and elastic. Such a change could be accounted for only upon the supposition that the cavity communicated directly with some large blood-vessel. On incision the swelling was found to be filled with blood, mostly coagulated. Most of the coagula were soft and dark-colored, but a globular mass, about the size of a lemon, which escaped last, was light in color, quite firm, and distinctly laminated. An elastic tourniquet allowed a satisfactory inspection of the cavity, at the bottom of which blood was seen trickling from a lateral opening in a vein of considerable size. The direction and situation of the vein was that of the vena comites of the profunda artery, and a ligature was applied above and below the opening by means of an aneurism needle. Four months afterward the patient was entirely well. In this case the absence of cardiac lesion, external violence, or unusual muscular exertion warrants the suspicion that the vein was abnormally weak at the seat of rupture, which suspicion is corroborated by a varicose condition of the long saphena vein of the opposite limb.

The alteration in tension, which can be due only to a fresh extravasation, affords almost positive evidence of communication between an open blood-vessel and the sac, and must be regarded as the diagnostic mark which allows the exclusion of an ordinary hematoma.

A résumé of the scattered literature of the subject accompanies the report of this case, and shows that some very remarkable examples of this accident have been recorded. Morgagni found a rupture of the vena azygos, the vessel being extremely varicose. Portal describes a case of rupture of the superior vena cava, occurring in a woman who died

suddenly in a cold bath. Mr. Else, surgeon to St. Thomas Hospital, wrote a very interesting article "Of tumors formed by ruptured veins sometimes mistaken for aneurysms," which was published in the third volume of *Medical Observations and Enquiries*, in 1769. In one of these cases occurring in the leg, the leg was actually amputated for the supposed aneurism, subsequent dissection showing the lesion to be in the vein not the artery.

#### BUSINESS MANAGEMENT OF INSANE HOSPITALS.

WE notice, in the ninth and last Annual Report of the New Jersey Insane Asylum at Morristown, that a change is to be made in its form of management.

Hitherto a medical superintendent has had general charge of all matters, both medical and business, and has had two medical assistants. Now the managers have undergone a change of faith, and though the number of patients continues the same—upward of seven hundred—they propose to separate the medical from the business department, placing the former under the care of "a competent alienist of advanced views, to be called Medical Director," with four medical assistants, and the latter under the care of a business man to be called "Warden."

The managers call this change a "radical" one, and it certainly is. There can be no doubt of the wisdom of increasing the number of assistants, as hitherto the number must have been very inadequate for the ordinary routine work. They might go even further and appoint a special pathologist, and still have a staff none too large to do the medical work thoroughly.

As to the wisdom of placing the "business concerns of the asylum under the charge of a warden, who shall have sole control of them," we have considerable doubt.

It is an excellent idea to relieve the superintendent of an insane hospital of as much drudgery as possible, but to do this by placing the institution under two heads may not in the end prove to be for the best.

Almost every detail in the management has a bearing on the medical care of the patients. Thus, work on the farm, in the workshops, or buildings; the quality of the provisions which are bought; the clothing and bedding provided; the heating, lighting, and plumbing, and many other matters that might be classed as of a business nature, are all of a medical character in their relation to the hospital.

There should be one head-officer, to be responsible for the entire management of the institution, and not two, as sooner or later there will surely be a difference of opinion. And, as the care of the

insane is essentially medical, he should be a medical man.

The JOURNAL is always glad to announce any real progress in the care of the insane, and, with the above exception, we heartily commend the advanced step taken by the managers of the Morristown Asylum.

#### A NEW TREATMENT OF SCIATICA.

EVERY physician in general practice must have at different times realized how unsatisfactory are all the modes of treating sciatica. Anodynes have failed, or are required in doses so large and so frequent as to be a source of danger to the patient. All the machinery of the revulsive medication, from rubefacient terebinthine liniments to linear vesication, the actual cautery, or punctiform (Paquelin) cauterizations, have been brought to bear upon the suffering member. Electricity in all its forms has been tried and frequently proved disappointing. Local anodynes (solutions of menthol, belladonna, ether spray, chloroform) may have rendered some fleeting service. The general tone of the organism has been fortified by quinine, and the quality of the blood improved by iron and cod-liver oil, but the vitality of the *locus minoris resistentie* (that "greatest and worst nerve of the body," as we have heard patients say) still remains depressed. Anti-rheumatics have been tried from salicylate of sodium to colchicum and iodide of potassium, all to the point of tolerance, but all to little effect. Nerve-stretching remains, but that somewhat delicate and difficult operation has been reserved as a last resort. In view, then, of the want of success which has attended the old methods, a new method of treatment which promises comfort to physician and patient will be welcomed.

Debove has lately proposed refrigeration by chloride of methyl in sciatica, as a medication of singular efficacy. This substance, which is obtained by distilling together methyl alcohol, sodium chlorate, and sulphuric acid, is a colorless gas, slightly soluble in water, with sweetened taste and odor; when projected on a part of the body from a suitable siphon bottle, it is attended with the production of intense cold, followed by intense smarting, and if the action be sufficiently prolonged, considerable erythema and even vesication. The benefit which is claimed from this remedy would seem then to be due not so much to the refrigerant as to the subsequent counter-irritant and vesicant effect. Debove, in a late number of the *Bulletin Général de Thérapeutique*, thus explains the principle and *modus operandi* of his method:—

"When we employ revulsion under any form whatever (vesication, punctiform cauterization, etc.) for a neuralgic affection, we act on certain of the sensory extremities of the painful nerve, but we respect a far greater number of these nerve termi-

nations because it is not possible to multiply to any great extent our vesicatories and cautery points. A process of revulsion which may be extended to the totality of the member innervated by the affected nerve will be then of far greater efficacy. This process I have realized in employing, as a revulsive, *congelation*. To this end I have had recourse to chloride of methyl, which is readily obtainable in commerce, and with which you may produce a speedy refrigeration. I practise with this agent, using for the purpose a siphon bottle furnished with suitable stop-cock and beak, pulverizations along the diseased nerve, directing the spray especially upon the *points douloureux*. This spraying ought not to last longer than a few minutes. It is much less disagreeable than the actual cautery, and (what is more important) it is followed by *instantaneous disappearance of the pain*. I have by this means cured patients who long had been sufferers, and who had obtained only partial relief from other revulsives. Ordinarily one *séance* suffices to cause the pain to completely disappear; sometimes, nevertheless, a second *séance* is necessary; but always after the first *séance* the pains are considerably lessened. When you prolong the spraying a little too long, you produce vesication. Although this is an accident of little importance, I think it better to guard against it, and as a precautionary guide, I habitually consult the feelings of the patient; when they tell me that the sensations which they experience resemble the pain which the punctiform cautery would occasion, I cease the pulverization."

This mode of treatment was lately discussed at a meeting of the Academy of Medicine. Desnos reported four cases of sciatica in which this method was tried; in three it was completely successful. The spraying from a siphon bottle was performed with great precautions, occupying only a few seconds. Rendu had found that a liability to the production of eschars follows the careless or too free use of this new medication: nevertheless, in one or two stubborn instances the most gratifying amelioration, and even cure, resulted. Binequi finds the methyl chloride a revulsive rather than an anodyne; in one rebellious case in his practice it was signally beneficial. Sevestre claims to have cured one inveterate case of sciatica after daily applications for two months of the methyl spray. Legroux has also found spraying with this substance useful in the intercostal neuralgias of the tuberculous. Robin, in December, obtained a striking cure by this means, in a patient forty years of age who had for six months suffered from sciatica with atrophy of the limbs; he was cured after two applications of the methyl, which were followed by vesication and intense pigmentation of the congested region. Letulle has treated two patients by the same process; the one was affected with sciatica from neuritis, and was completely cured; the other, who was suffering

from Pott's disease, complained constantly of diffuse lumbar pains, and derived the greatest benefit from the methyl-chloride spray.

It is to be hoped that the favorable experiences of these French practitioners with this new remedy may be followed by equally good results in this country, and that this painful, inveterate malady may become less of an opprobrium to medicine and surgery.

#### ANNUAL REPORT OF THE NEW YORK STATE BOARD OF CHARITIES.

THE eighteenth annual report of the New York State Board of Charities was presented to the Senate at Albany, January 27th. The statistics of the returns from the various institutions, analyzed and tabulated, show the appraised value of the property of all kinds held for charitable and correctional purposes in the State; the receipts and expenditures for public relief for the fiscal year ending in September, 1881; the number of persons cared for during the year, and the number under care at its close. The report states that the increase in the number of State paupers is wholly due to the defective administration of the Federal laws respecting immigration, by which large numbers of infirm alien paupers find their way to this State to burden the cities, towns, and counties, who should be rejected at the ports at which they land, and then returned to the vessels bringing them, as the law prescribes. The total valuation of State charitable property on October 1, 1884, was \$16,856,670, against \$13,303,478 on October 1, 1883. The receipts and expenditures were both about \$650,000 more than during the preceding year.

#### MEDICAL NOTES.

—We understand that Dr. P. Brynberg Porter, of New York, has been appointed editor of *Gaillard's Medical Journal*, and will have as collaborators Drs. T. Gaillard Thomas and George T. Harrison, of New York; Hunter McGuire, of Richmond, Va., and C. H. Mastin, of Mobile, Ala.

—*A propos* of the dangers of telegraphy as an occupation, to which attention has been called of late, we note the occurrence in a Scottish telegraph office of three cases of lunacy among the operators in as many successive years. An American publication devoted to telegraphic matters mentions two recent cases of operators dying at their posts. A correspondent of the *Edinburgh Daily Express* writes: In the Edinburgh office no fewer than three cases of insanity have occurred this year. It is believed among the operators that reading by sound for prolonged periods is the chief cause in producing this terrible disease. This is confirmed by what Dr. Savage writes in his recent book on "Insanity and Allied Neuroses": "Work of a monotonous

character is injurious, and assists in producing mental disorder. But such work is comparatively rare. To my mind the letter-sorter, the proof-reader, and persons employed to check mechanical labor, run the greatest risk of breaking down from this cause. A clerk or an accountant may suffer from the monotony of his work, but with all its dryness it is not so absolutely uniform as that of the man who sorts letters, signals trains, or corrects proofs under the pressure of time."

— *The Lancet* issues a warning against the various devices recommended for reducing weight, saying that no specific measure will suffice which is not injurious to health. The only safe rule which is of any effect in this direction is that of *slow eating*, as an aid to thorough mastication and a prevention of repletion.

— The apothecaries of the army and navy are ambitious for higher recognition. They are required to pass a technical examination in elementary chemistry, materia medica, pharmacy, and botany, and they now want a title and rank. They have, therefore, introduced a bill in Congress, providing that the apothecaries of the army and navy shall receive a commission, those of the army ranking with second lieutenants, and those of the navy with ensigns, but that they shall not be in the line of promotion.

— The Massachusetts Emergency and Hygiene Association has prepared a course of five lectures upon School Hygiene, to be delivered in the hall of the English High School in Boston, at 10 a.m., February 14th, 21st, and 28th, and March 7th and 14th. The subjects and lectures in order are: "Heating and ventilation," by F. W. Draper, M.D.; "The use and care of the eyes, especially during school-years," by C. H. Williams, M.D.; "Epidemics and disinfection," by G. B. Shattuck, M.D.; "Drainage," by Frank Wells, M.D., and the "Relation of our public schools to the disorders of the nervous system," by C. F. Folsom, M.D.

— It is said that Dr. Koller, the discoverer of the anæsthetic properties of cocaine, has recently fought a duel. His antagonist, one of Billroth's assistants, received a wound that may prove fatal.

— A case of death from the administration of ether is reported from Adelaide, N. S. W. The autopsy showed the deceased to have a fatty heart.

— A record of abnormally low temperature in a case of double pneumonia is reported in *The Australian Medical Gazette* for November, 1884. The maximum temperature on the first three days of the disease was 99°, 99.1°, 100.5° (the second lung becoming affected). After the fourth day it did not go above 99.6°, and after the sixth day it was not above normal, though the lungs did not become clear till the seventeenth day.

— Sir Joseph Lister has received from the Emperor of Germany the "ordre pour le mérite" for Science and Arts.

#### NEW YORK.

*Death of Louis Elsberg, M.D.*—The profession and the scientific world in general have met with a very serious loss in the death of Dr. Louis Elsberg, the distinguished laryngologist, which occurred February 19th. Dr. Elsberg had been suffering for two or three years with Bright's disease, but the immediate cause of death was an attack of pneumonia, which was of very short duration. He was born at Iserlohn, Prussia, on the second of April, 1836, and was, consequently, just in his prime. His parents removing to this country and settling in Philadelphia while he was a boy, he studied medicine at the Jefferson College, where he received the degree of M.D. in 1857. Having, while yet a student, become particularly interested in diseases of the throat, he went abroad immediately after graduation to pursue a course of special studies in this department, and became a pupil of Tabold, in Vienna.

On his return to America he commenced the practice of his specialty in New York, and in 1861 was made professor of laryngology in the medical department of the New York University, a position which he occupied for seventeen years. The year after he assumed this chair, the Faculty established for him a public clinic for diseases of the throat and nose, which is said to have been the first of its kind in the world, and his fame as a laryngologist soon spread throughout the world, bringing him many honors and a handsome fortune. As an operator he was almost unrivaled in skill, and his medical writings have always occupied a very high position in their department. Among the other literary labors to which he devoted himself was the conducting of the admirable *Archives of Laryngology*, published by the Putnams, in which he was much interested, and of which he remained the editor up to the time that the journal was discontinued last year. He was the founder, and first president, of the New York Laryngological Society, as well as the American Laryngological Association, and was a member of many other societies, including the Academy of Sciences, of which he was librarian. In 1876 he was married to Miss Mary van Hagnm Seville (who survives him), and in 1880 he resigned his position at the University and went abroad for a year, in order to take a rest from his arduous professional work; being the recipient of much generous hospitality in every city of Europe that he visited. At the time of his death he held the position of professor of laryngology at Dartmouth Medical College, as well as at the New York Polytechnic; and at the recent annual meeting of the New York Academy of Medicine he was elected corresponding secretary.

## WASHINGTON.

*Army Medical Museum Building.*—The most interesting medical event of this session of Congress has been the passage, on Monday, February 16th, by the House of Representatives, of the bill providing for a building for the records, library, and museum of the surgeon-general's office of the United States Army. The bill reads that a brick and metal fireproof building shall be constructed upon the government reservation in the vicinity of the National Museum and the Smithsonian Institution. The cost is not to exceed \$200,000.

There was some opposition to the bill in debate. Mr. Potter from New York was afraid that the course thus entered upon would end in a national library of medicine, a national collection of medical specimens, and, finally, in a national college of medicine. He favored turning over all the specimens in the museum to a Philadelphia medical college, or, better, burying them and covering them over with green grass, and thus he hidden from sight forever. He did not approve of the general government entering upon the field of education; that should be left to the States.

Mr. Nutting, of New York, opposed the bill in the interests of the Congressional Library, which has asked for a separate building sufficient to hold all the books needed by the government. To erect a number of buildings for separate libraries would in the end defeat any such project.

Mr. Thompson, of Kentucky, would put the 52,000 volumes of records in the New War Department and Pension Office buildings, the specimens in the Smithsonian, and the books in the library of Congress.

Mr. Theodore Lyman, of Massachusetts, spoke forcibly in favor of the bill; alluded to the germ theory of disease, and to the study of it now being so thoroughly carried on at the National Medical Museum, as influencing not only our knowledge of the cause of disease, but also its prevention by inoculation. If our fish commission, signal service, and our national surveys, are worth preserving, then has the Medical Museum a double claim on our fostering care.

Mr. Long, of Massachusetts, seconded the remarks of his colleague by alluding to the practical importance of preserving from threatening destruction this valuable material, now kept in a tumble-down, unsafe building.

Messrs. Hohman, Slocum, and Follett, all favored the bill, alluding to the imminent danger by fire of the present accommodations; to the fact that the building is already twelve inches out of plumb and has begun to tumble down; that there is no room for this purpose in other public buildings; and of the immense importance of the material to members of the medical profession.

The bill passed by a vote of 181 yeas to 23 noes, and now goes to the Senate, where its friends have strong hopes for it unless the question of location should be discussed, as objections have been raised to using any more of the government reservations for the erection of buildings.

*Asiatic Cholera.*—The Committee on Public Health presented a resolution to the House of Representatives on February 17th, which was referred

to the Committee on Appropriations, and which resolves: That from a probably well-founded apprehension that Asiatic cholera may be introduced into this country during the present year; and that it is very desirable that the introduction of all contagious, infectious, and epidemic diseases into this country be prevented if possible; that there shall be provided in the proper annual bill an appropriation of \$500,000, to be expended in the discretion of the President of the United States, through such governmental agencies as he may designate for the purposes indicated. And, further, that there should also be provided an appropriation of \$25,000 to pay the per diem and necessary expenses of the National Board of Health for the ensuing fiscal year.

## Correspondence.

## SPRAY IN OVARIOTOMY.

Boston, February 17, 1885.

MR. ERROR,—The following is an extract from a recent work by Dr. Emmet (*Emmet's Principles and Practice of Gynecology*, p. 715): "In this country I do not know of any prominent operator who now employs the carbolic-acid spray."

This statement implies that the writer is not persuaded of the value of spray in ovariectomy. My own experience has led me to an opposite opinion. Indeed, I should not like to do a laparotomy for any purpose without antiseptic spray. I have been led to this conclusion by the results of one hundred and eighty-three cases of removal of cystic ovaries, of which I have lost only twenty-one—but more especially by the result of the last one hundred of these cases only ten of which were fatal while thirty-eight were consecutively successful. I feel that to omit the antiseptic spray would be to deprive the patient of one of the ready and efficient elements of success.

As I can hardly hope for much better results than those I have cited, and being quite content to let well alone, I shall hesitate before disturbing my present plan of operation by giving up a detail to which I attach much importance.

I am, very respectfully, your obedient servant,

JOHN HOWANS, M.D.

## HARVEY'S MANUSCRIPT LECTURES.

To the Editor of the Boston Medical and Surgical Journal.

SIR,—The MS. of the original lectures at the Royal College of Physicians by William Harvey, including his earliest observations on the heart and circulation, and delivered by him in and after 1616, were rediscovered in the British Museum in 1877. I gave a description of the little book, and exhibited an autotype copy of one page in my Harveian oration at the college in 1877. I then suggested that it would redound to the honor of the present generation, and be an advantage to the history of medicine, if the whole of the lectures could be published in autotype, accompanied by an intelligible transcript. The handwriting is so crabbled, and there

are so many abbreviations, that no one but an expert could succeed in understanding them. Without the valuable aid of Mr. Bond, now the chief of the British Museum, I should have failed in my attempts to understand much, if anything, of the lectures. By dint of severe labor Mr. Bond succeeded in interpreting one of the lectures, and has now been good enough to make me acquainted with a gentleman who will undertake to transcribe the whole of the lectures. My inquiries lead me to believe that no publisher could be found to undertake the risk of publication in the form proposed, unless guaranteed a certain amount of professional support. On the other hand, I calculate that if from two to three hundred gentlemen would engage to each take a copy at a price not exceeding two guineas, the work might be safely proceeded with. Autotyping is a much more expensive process than ordinary printing, and the honorarium to the transcriber would necessarily add considerably to the cost.

May I ask your permission to submit the question to my professional brethren through your journal whether they will aid in this labor of love of, and admiration for, our great prototype of the scientific physician? I am permitted to state that the Presidents of the Royal Colleges of Physicians and Surgeons warmly support the undertaking.

I am, sir, your faithful servant.

EDWARD H. STEVERING, M.D.

17 Manchester Square, W., February 2, 1885.

P. S. Any communications on the subject may be addressed to me, or to Messrs. Churchill, 11 New Burlington Street, W.

### Miscellaneous.

#### RAILWAY ACCIDENTS AND COLOR-BLINDNESS.

DR. WILLIAM THOMSON, writing upon this subject in the *Popular Science Monthly*, says: "It has not been the duty of the writer to investigate cases of accident which might have been caused by defects of sight, but he has been assured by officials that a solution will hereafter be found in them for those hitherto insoluble mysteries where men, otherwise credible, have so flatly contradicted themselves and the circumstances of the case. By one prominent officer he was told that, being upon a train at night, delayed by some slight accident, he himself took a red lantern, and, going a proper distance back, placed himself on the track in the way of an oncoming train, but finding his light not observed he was compelled to dash it into the cab to attract the engineer's attention and arrest him in his progress to a collision. Upon the examination of another engineer, his superior officer being present and convinced of his marked color-blindness remarked that, but a short time before, the man had run into the rear of a train properly protected by a red light in the hands of a brakeman some distance in the rear; that the most careful investigation had resulted only in the suspension of the brakeman for not having gone far enough back; but that he was now satisfied that the color-blindness of the engineer had been the real cause of the acci-

dent. Some slight or minor accidents recently led to the discovery that another engineer had by some oversight not been tested in his division, and this led to his examination and detection there, and to his conviction by the writer as a color-blind. Still another case now presents itself. An engineer some time ago ran over and killed a brakeman, holding a danger-signal on the track in front of his engine, and no satisfactory explanation could then be given; but the division examiner predicted that he would probably be found color-blind, and on his examination this proved to be the case."

#### HOW TO SEE THE SHADOWS OF ONE'S OWN RETINAL VESSELS.

A WRITER in the *Australasian Medical Gazette* (November, 1884) shows how to demonstrate, on one's own person, the retinal vessels and yellow spots. His method is as follows: Standing at a short distance (ten or twenty feet) from a lighted gas-jet in a dark room, and covering one eye, say the left, with the left hand, the observer takes between the forefinger and thumb of the right a strong convex lens, and holds it at about its focal distance in front of the right eye. Then, steadily gazing at the light through the centre of the lens, he shakes the lens rapidly backward and forward along its axis, or up and down, or from side to side. After a few seconds the shadow of the fovea centralis appears in the axis of vision as a light yellow patch studded with dark coarse granules. Simultaneously the retinal vessels in the region of the yellow spot, including the finest capillaries, appear as dark cords against the yellow light. The appearance is not unlike the plate (No. 72) in the last edition of Mr. Nettleship's book on diseases of the eye, except that the difference between the arteries and veins is not so marked, and that one gets a more extensive view, seeing the shadow of the retinal vessels as far as the optic disc. The outline of the shadow of the fovea centralis, which falls upon the most sensitive part of the retina, the yellow spot, is well defined; whilst the outline of the shadow of the optic disc cannot be distinctly seen, as it falls upon a much less sensitive part of the fundus. The shorter and more rapid the movements of the lens the sooner the shadows of the retinal vessels and fovea centralis appear, and the more distinctly are they seen.

The chief other method of accomplishing this end is that of Purkinje, to wit: Whilst looking at a dark ground in a room one concentrates with a lens the rays of light from a gas-jet, and throws them obliquely on the sclerotic immediately behind the sclero-corneal junction, or upon the cornea itself. On rapidly moving the lens up and down, or from side to side, one then sees projected on the dark wall the image of the retinal vessels.

By this method the rays of light are thrown obliquely on the sclerotic or cornea, instead of being, as in the method first described, directed along the visual axis, and consequently falling perpendicularly on the surface of the cornea. The image of the retinal vessels is seen against the yellow light, and

is not projected on a dark well. The author claims that while the shadow of the fovea centralis is faint and difficult to recognize by Purkinje's method, by his method it is as clearly defined and as easily seen as the shadow of the retinal vessels.

REPORT OF THE SALEM (MASS.) HOSPITAL.

The superintendent lately presented the tenth Annual Report. The number of patients admitted to the hospital during the past year was 140. Of these 42 were medical, 98 surgical; 82 were males and 58 females. The average number of days passed in the hospital by free patients was 32½, and by those paying board, 13½. Board was furnished to free patients 553 weeks, and to those paying board 14 weeks. The Eastern Railroad bed was occupied 216 days, the Nantuxeng Mills' 170, and the Salem Lead Company's 20, and 63 days' board was furnished to United States patients. The number of patients paying board was much less than in previous years, as, owing to the increase in the funds, the trustees did not wish board exacted from any who could not easily afford to pay. Thus

many were admitted free, who, in former years, would have been expected to pay something at least. The largest number of patients in the house at any one time was 21; the smallest number, 8. The average cost of board was \$2 per day. There were of out-patients: Medical, 332; eye and ear, 295; surgical, 346; and dental, —.

SANITARY COUNCIL OF THE MISSISSIPPI VALLEY.

The executive committee of the Sanitary Council of the Mississippi Valley has fixed the date of the seventh annual meeting of the Council for Tuesday, March 10th, prox., and for the place the city of New Orleans. This is about a month earlier than these meetings are usually held, and the committee assigns as a reason for the change the probability of Asiatic cholera appearing in the country, and the uncertainty concerning national legislation on public health matters. Invitations are extended to all State and local authorities in the valley, and to representatives of commercial and transportation interests.

Deaths reported 2,897; under five years of age 1,043; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers and diarrheal diseases) 421, lung diseases 509, consumption 400, diphtheria and croup 172, scarlet fever 54, measles 42, typhoid fever 57, diarrheal diseases 31, whooping-cough 23, erysipelas 22, meningitis 22, malarial fever 15, erysipelas 14, puerperal fever 9, typhus fever one, small-pox one. From typhoid fever, Philadelphia 15, New York, Chicago, and Baltimore four each. From diarrheal diseases, New York 8, New Orleans 6, Chicago and Cincinnati three each, Brooklyn, Baltimore, and Nashville two each, Boston, District of Columbia, Lowell, and Lynn one each. From whooping-cough New York and Brooklyn eight each, Philadelphia three, Boston two, Baltimore and District of Columbia one each. From erysipelas meningitis New York and Philadelphia four each, Chicago three, Fall River, Woburn and Chelsea two each, Boston, Baltimore, Nashville, Worcester, and Taunton one each. From malarial fevers New York 10, Brooklyn two, Baltimore one. From erysipelas New York five, Philadelphia four, Brooklyn, Boston, Baltimore, Cincinnati, and New Orleans one each. From puerperal fever Brooklyn, Boston, and District of Columbia two each, Philadelphia, Chicago, and Baltimore one each. From typhus fever Fall River one. From small-pox Chicago one.

The meteorological record for the week ending February 14th, in Boston, was as follows, according to observations furnished by Sergeant O. R. Cole, of the United States Signal Corps:—

Date.	Barometer.	Thermometer.		Relative Humidity.		Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FEBRUARY 11, 1885.

GUTIERREZ, JOHN, passed assistant surgeon. When relieved at Key West, Fla., to proceed to Charleston, S. C., and assume charge. February 11, 1885.

KYLLOCH, P., assistant surgeon. To report to Passed Assistant Surgeon Peckham at Wilmington, N. C., for examination for promotion. February 10, 1885.

GLENNAN, A. H., assistant surgeon. Relieved from duty at New Orleans, La., to proceed to Key West, Fla., and assume charge. February 11, 1885.

#### RESIGNATION.

HEATH, W. H., passed assistant surgeon. Resignation accepted, as tendered, by the Secretary of the Treasury. February 11, 1885.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM FEBRUARY 11, 1885, TO FEBRUARY 20, 1885.

PAULK, J. D. H., captain and assistant surgeon. Leave of absence further extended seven months on surgeon's certificate of disability. S. O. 10, A. G. O., February 17, 1885.

PURLEY, H. O., captain and assistant surgeon. Granted leave of absence for one month, to take effect on March 5, 1885. S. O. 16, Department of Dakota, February 10, 1885.

ROBINSON, S. G., captain and assistant surgeon. Relieved from duty at Ft. Spokane, W. T., and ordered for duty as post surgeon, at Fort Klamath, Oregon. S. O. 23, Department of Colorado, February 9, 1885.

RYAN, J. R., first lieutenant and assistant surgeon. (Recently appointed.) Assigned to duty at Fort Sill, Indian Territory. S. O. 23, Department of Missouri, February 11, 1885.

Cases reported in Boston: scarlet fever 32, measles 23, diphtheria 22, and typhoid fever three.

In 108 cities and towns in Massachusetts with an estimated population of 1,320,070 (estimated population of the State 1,355,104) the total death-rate for the week was 20.57 against 19.15 and 15.00 for the two preceding weeks.

In the 28 greater towns of England and Wales with an estimated population of 8,762,354 for the week ending January 31st: Deaths reported 4,188; infants under one year of age 897; acute diseases of the respiratory organs (London) 556, whooping-cough 141, measles 58, scarlet fever 56, fever 43, diphtheria 35, diarrhoea 32, small-pox (London 29, Liverpool two) 31.

The death-rates ranged from 13.5 in Birkenhead to 36.6 in Norwich; Birmingham 23.7; Bradford 22.6; Hull 19.1; Leeds 25.8; Leicester 20.7; Liverpool 27.1; London 24.1; Manchester 26.5; Nottingham 25.2; Sheffield 23.7. In Edinburgh 21.4; Dublin 35.5; Glasgow 33.8.

For the week ending January 31st, in the Swiss cities there 44 deaths from lung diseases, consumption 33, diarrheal diseases 7, diphtheria and croup 6, small-pox 4, whooping-cough 4, puerperal fever 3, typhoid fever 2. The death-rates were: at Geneva 25.5; Zurich 29.9; Basle 28.7; Berne 39.3.

#### BOOKS AND PAMPHLETS RECEIVED.

Tenth Annual Report of the Salem Hospital. Salem, Mass. 1885.

Helps to Health: The Habitation, the Nursery, the School-room, and the Person. With a Chapter on Health Resorts. By Henry C. Burdett. With 19 illustrations. London: Kegan Paul, Trench & Co. 1885.

Ueber die Stielversorgung nach Myomperone. Von A. Martin. Separat. Abdr. aus der Berl. klin. Wochenschr. 1885.

The Journal of American. An Address delivered before the Philadelphia County Medical Society, January 14, 1885. By W. M. Welch, M.D., Retiring President. (Reprinted from the Proceedings of the Society.) Philadelphia. 1885.

Some Important Points connected with the Surgery of the Urinary Organs. Lectures delivered in the Royal College of Surgeons, London. By Sir Henry Thompson, M.D., F.R.C.S. Illustrated. Philadelphia: P. Blakiston, Son & Co. 1884.

Report of Proceedings of the Illinois State Board of Health. Adjourned Meeting, February 5-7, 1885.

Biennial Message of John M. Hamilton, Governor of Illinois to the Thirty-fourth General Assembly, January 30, 1885.

The Care of Infants. A Manual for Mothers and Nurses. By Sophia Jex-Blake, M.D. London: Macmillan & Co. 1885.

Department of the Interior. Bureau of Education. "Building for the Children in the South." Washington. 1884.

The International Encyclopedia of Surgery. A Systematic Treatise on the Theory and Practice of Surgery by Authors of Various Nations. Edited by John Ashhurst, Jr., M.D. Illustrated with chronolithographs and woodcuts. In six volumes. Vol. V. New York: Wm. Wood & Co. 1885.

## CASES OF CONGENITAL MUSCULAR RIGIDITY, OR LITTLE'S DISEASE.

BY E. H. BRADFORD, M.D.,

*Surgeon to Boston City and Children's Hospitals.*

Any one who has seen a number of idiotic children will have noticed that many of them suffer from a peculiar disability and distortion of the hands and feet, and an inability to control and direct the action of certain muscles. On examination it will frequently be found that the affected muscles are fairly nourished and are unusually firm to the touch, and that they have not lost their contractility; in fact, that they are in a state of spasmodic contraction, that is, in a condition the reverse of paralysis, although the limb is frequently as useless as if paralyzed, voluntary control being impaired or lost. This condition has been classed as a cerebral paralysis, although this expression seems inapt, as the term paralysis, when strictly used, describes a different state; furthermore a similar condition may sometimes be seen where there is no mental impairment, and where the intelligence and symptoms do not justify an opinion that the affection is of cerebral origin.

This "congenital muscular rigidity" was first described as an affection by Little, of London, in 1853, and Rupprecht with justice suggested that the name of Little's disease be applied to it in view of the fact that the pathology at present is conjectural. The following cases will serve as an illustration:—

CASE I. B., a boy aged four years, is said to have been healthy as an infant and that there was no trouble at birth; the child is well nourished, but has never walked, and is apparently deficient mentally and is unable to talk.

Both legs are flexed at the knees, the feet are fixed so that the heels cannot be brought to the floor, the adductor muscles are slightly contracted. These contractions are aggravated when the patient attempts to stand or to move about leaning on a chair or table. The right arm and hand are also in a state of rigidity. The spasm of the affected muscles is not clonic, and the rigidity can be overcome by applying with the hands a constant pressure, but the correction

only lasts while the pressure is maintained. Some permanent contraction, however, of the calf muscles appeared to be present, as the foot could not be brought to an angle with the leg less than a right angle.

There was no atrophy or impairment in the circulation of the limb, and the tissues were firm and hard to the touch, but a diminution of sensation was noticed on the soles of both feet and on the anterior surface of the legs. The knee reflex was exaggerated, but the cremaster and abdominal reflexes were not. No disturbance of the intestines or bladder was noticed.

The tendines Achillis were divided under ether, the knees pulled straight, and a plaster-of-Paris bandage applied to the feet (placed in an over-corrected position) and to the leg and thigh. No pain followed and the stiff bandage was not removed for six weeks. The deformity was found to be entirely corrected and the patient was able to stand well.

A noticeable fact is that the tonic spasm to be seen in the limbs did not disappear under complete anesthesia.

An appliance was furnished to be worn constantly as a preventive to relapse. Four months later the child's condition was reported to be the same; there being no return of the deformity.

NOTE.—Circumcision was done in this case, a phimosis being present; the operation, however, had no beneficial effect on the patient's condition or deformity.

CASE II. P., a girl twelve years of age, of perfect health and excellent family history, suffered since she has walked from a disability of both lower extremities. In walking she was unable to place her heels upon the ground but supported her weight entirely upon the ball of the foot; the knees turned in badly in walking.

The child had not suffered severely from any infantile disease, and though an excitable, active, and nervous child, was intelligent in every particular. No difficulty had taken place at the child's birth, the mother's labor being normal and not protracted.

Tenotomy of both tendines Achillis was performed and the limbs fixed in a corrected position for three weeks. Ankle supports with additional steel rods to pass up the legs were applied, and the child allowed to walk in three weeks. At the present time, six months after the operation, the girl walks entirely upon the flat of the foot, striking the heel at every step normally, and there is no tendency to relapse. The tendency to in-knee remains however.

CASE III. A girl fifteen years old with some mental deficiency, not sufficiently marked as to be termed idiocy, limped badly in walking from a disturbed condition of the right limb, which was held, when standing, with the knee bent and the heel raised four inches from the floor; there was also contraction of the adductors. By the employment of gradual manual force the rigidity of the muscles could be partially overcome and the heel forced down to the floor, but the front of the foot could not be brought above a right angle with the leg. The limb could also be straightened at the knee temporarily by the use of persistent force, the distortion returning, however, immediately.

After a month's attempt to stretch the tendo Achillis by means of appliances, with but partial success, tenotomy was performed with immediate correction and fixation by means of plaster bandages. After three weeks appliances were furnished designed to allow motion beyond the corrected position, but not in the direction of distortion.

At the present time, three years after the operation, the patient is reported to walk with the heel well on the floor and the limb straight at the knee, but there is still some inversion of the limb.

This patient suffered somewhat from rigidity of

the muscles of the right forearm which gave a stiffness to the motion of the fingers. Nothing was attempted to relieve this condition.

CASE IV. D. F., aged seven, was sent to the Children's Hospital with a diagnosis of hip disease and with a history of having always limped with the right lower limb. A condition of rigidity of the leg muscles was found without atrophy or flaccidity or loss of temperature. The heel was, in walking, raised from the floor and the knee bent, with a slight adduction of the thigh and inversion of the foot. The other limbs were normal and the child's intelligence perfect. The tendo Achillis was divided, the foot forcibly flexed, the limb straightened, and the whole done up in a plaster-of-Paris bandage, which was worn for several weeks, after which a light apparatus was used. The child, at the end of two months' treatment, was able to stand with the heel well down to the ground and to raise the toes slightly when standing.

CASE V. Infant, nine weeks old, with a spasmodic contraction of the extensor muscles of both legs, and the flexors of the thigh, to such a degree that the lower extremities, while the child lay on its back, were held stiff at an angle of  $15^{\circ}$  above the plane of the trunk, the legs being more extended than the thighs. The feet were strongly flexed and the adductors of the thigh slightly contracted.

The upper extremities were not affected, and the child was said to be healthy.

The spasmodic condition was noticed immediately after birth; it relaxed during sleep. The child was otherwise healthy. No especial difficulty at birth was mentioned as having taken place.

CASE VI. A girl aged six years, quite intelligent, but with a spastic deformity of the left hand and foot. Treatment for a while was attempted in correcting the deformity of the foot by means of plaster-of-Paris bandages, but without success. Tenotomy was, therefore, performed, followed by immediate correction and fixation with plaster bandages. The patient's condition was such, two months after operation, that, in walking, the heel touched the floor and the front part of the foot raised. No attempt at treatment for the hand was made. The subsequent history of the case was not obtained.

CASE VII. L., three years old, born without difficulty, a healthy child; never had convulsions. The child never moved her legs as freely as other babies did, and when a year and a half old it was noticed that the right knee was rather stiff. As the child grew this became more noticeable. The child, at the present time, is unable to walk; it has never walked or learned to creep, but can stand leaning on a chair. On attempting to use the legs in the motion of walking, they become crossed spasmodically. The child is also unable to put the heels to the floor when standing, although there is no permanent contraction of the gastrocnemius muscle. No atrophy or flabbiness of the muscles. The child is perfectly intelligent, is healthy. No treatment was attempted.

CASE VIII. G., a girl ten years of age, well-built, and with the appearance of health, presented a spastic condition of the left arm and left leg, with a slight spastic equina varus deformity without

atrophy and with exaggeration of the knee reflex on the left side. Slight occasional strabismus was present.

No difficulty occurred at the child's birth, but severe convulsions took place when the child was a few weeks old. Convulsive seizures have occurred since at different intervals. No abnormality in the shape of the head was noticed.

The child could not be classed as idiotic, but appeared backward in intelligence.

No treatment beyond the application of a brace was accepted by the parents.

CASE IX. F., a boy eight years of age, healthy antecedents, and no severe sickness in infancy and early childhood. No difficulty at the child's birth. Peculiarity of the left side noticed when the child was thirteen months old: this peculiarity, however, did not follow any sickness. Increased tendon reflex of left knee. Spastic rigidity of left gastrocnemius and hamstrings. The adductors of the thigh not affected. The right side is normal. Patient can put the heel upon the ground, but, in walking, the heel is raised two inches from the ground, and the weight falls upon the ball of the foot. A stiffness in the motion of the left fingers and hands also noticed. Some atrophy of the extensor muscles of the fingers and of the muscles on the front of the leg, but no paralysis existed, and all motions could be made, though slowly. The spasm of gastrocnemius could be overcome by the persistent use of moderate force.

The child was perfectly intelligent and otherwise well-developed.

Attempts were made for several months to correct the distortion of the foot by an appliance and by massage, but no permanent benefit followed and tenotomy was advised, but declined by the child's parents.

From the above cases and from other observations, it may be said that the following symptoms are characteristic of this disorder: A tonic spasm of many of the symmetrical groups of muscles, the spasm appearing whenever any energetic movement is made by the patient in the affected group of muscles or on passive movements, the muscle, however, becoming relaxed at times if the patient's attention is not attracted; an increase of the deep tendon reflexes without diminution of the faradic contractility, or impairment of nerves of sensation, or interference with the trophic centres. The muscles affected are most frequently the adductors of the thigh and the calf muscles. This causes a peculiar gait, namely, a knocking-in of the knees with flexion at the knee and walking on the toes with inversion of the foot, distortions which are due, not to a paralysis or paresis, but to the fact that the action of certain muscles causes a more powerful contraction of the antagonistic muscles, either from an increased tendon reflex or from the fact that volition acts through too many motor centres or too powerfully. It has been said that the affection always affects both lower extremities, though, frequently, one to a greater degree than the other. A few of the cases here reported were, however, exceptions to this rule, and hemiplegic and not paraplegic. A spasm of the muscles of the eyes, causing strabismus, is sometimes seen,

and grimacing of the countenance and sometimes difficulty in swallowing. In one case the muscles of the tongue and of the right arm were the only ones affected. The intelligence is frequently impaired, the children learning to speak late, and noticeable as backward at school; but this is not invariably the case. The affection is usually not noticed until the child begins to walk, as awkwardness in the use of the limbs passes unobserved in infants and young children. The disease is not progressive in any true sense. As the child grows heavier, however, the disability may become more noticeable; and if the distortion is severe, a degeneration of certain of the muscles from disease may take place from disuse.

The characteristics of the disease are so marked that a diagnosis is easily made if it is borne in mind that the disease is of congenital origin; is usually first noticed in early childhood; that it is characterized by a rigidity of the muscles, chiefly of the adductors of the thigh and calf muscles, and by a peculiar gait.

The affection has, however, been confounded with hip disease, partly owing to the contraction of the adductors and the distortion, which somewhat resembles the distortion of hip disease, and partly because any lameness occurring in a child suggests to the superficial observer a "trouble at the hip," as it is usually termed.

More common is the error which classes congenital muscular rigidity with infantile paralysis — "teething palsy." The distinction is marked. The two classes of organic disease of the nervous system in infancy and early childhood are: first, the atrophic; second, the spastic. The first includes the so-called infantile paralysis: the muscles are flaccid, and undergo wasting; the faradic contractility is lost or diminished, and the galvanic contractility of the muscles may undergo the quantitative and qualitative changes termed "reaction of degeneration," and the reflex actions are abolished. In the second class, that is, the spastic, the muscles are in a state of tension: there is no wasting; the electrical reactions are normal, and the reflex actions increased, the deep reflexes being especially so.

The symptoms in congenital muscular rigidity resemble those sometimes observed in a compressive myelitis, as that from caries of the spine, namely, the spasmodic contraction of the muscles without impairment of sensation and with exaggeration of the deep reflexes. Caries of the spine at a stage of paralysis is characterized by a deformity of the spinal column and peculiar attitude of the trunk, absent in congenital spastic rigidity.

In regard to the pathology of these cases it should be borne in mind that a spastic muscular rigidity may be brought about by different causes, namely: (1) primary sclerosis of the lateral columns; (2) defects of the cerebral cortex near the fissure of Rolando; (3) trauma affecting the head or upper portion of the spinal cord at birth or afterward; (4) disseminated sclerosis of the cord; (5) compression of the cord.

It may be stated in general, to quote the words of Ross: "Spasmodic spinal paralysis is caused by a disease of the large ganglia cells in the third layer

of the motor area of the cortex of the brain, or of the fibres of the pyramidal tract which connect these with the ganglia cells of the anterior horns of the spinal cord."

Injury during birth has been supposed to be the cause of the affection; but of the cases here reported which I have been able to investigate there was no evidence or any injury at birth, or of any instrumental delivery, protracted labor, or breech presentation. In two cases of spastic condition of the arm, not here reported, the condition was evidently due in one to an injury of the head, with a depression of the skull, and a difficult labor (breech presentation with retarded delivery of the head), but in neither was any disturbance in the lower extremities present.

As has been said, the affection is frequently paraplegic (tetanoid paraplegia, Seguin); it is sometimes hemiplegic, but it is sometimes limited entirely to one lower extremity, as in case IV. This condition may occur coexistent with perfect health and without any tendency to progress.

In regard to treatment galvanization of the spine and warm baths, mentioned by some writers, appear to be without use. The condition of the patient, however, can by surgical treatment be improved, and in the lighter cases the deformity which is the chief impediment in locomotion corrected. This is the more important, as the patient's general health frequently is excellent, and also for the reason that continued disuse of the limb injures the unaffected muscles and increases the disability.

Rupprecht<sup>1</sup> pointed out the advantages of tenotomy in this class of cases, and also the permanent correction of the deformity by the use of this measure. Attempts were made to correct the distortion in several of the cases here reported by mechanical means alone, but in the majority the benefit was slight. Tenotomy of the tendo Achillis, followed by immediate fixation in a corrected position, enables the patient to walk on the flat of the foot; this relieves the flexion at the knee, but not the adductors of the thighs. This latter distortion, however, can in a measure be overcome by side steel supports connected with the shoes below, passing to the outer side of the leg and thigh, and fastened above to a waistband. The equinus deformity at the foot does not relapse when fully corrected by tenotomy. This was true in a case under Rupprecht's observation for six years, and in one operated on by me two and a half years ago, as well as in others under observation for a shorter time. Singularly enough, if the distortion is overcorrected, there is danger of the new position becoming as permanent and rigid. In case I, after treatment, the tendency to walk entirely upon the heel was very noticeable, and was attributed to the fact that to avoid the possibility of a relapse overcorrection was sought for by the retaining appliance used after tenotomy.

Stretching the muscles by means of weights and elastic straps, as has been recommended, was tried in several cases without much benefit, as well as forcible correction (without tenotomy) under ether and fixation by plaster-of-Paris bandages. It was found in two cases that the tonic spasm of the

<sup>1</sup> Volkmann's Klin. Vorträge, 172.

gastrocnemius, which relaxed in a measure under gentle passive motion, was in two cases to a degree persistent under profound anaesthesia.

In brief, it may be stated that tenotomy, followed by immediate correction and fixation, and retentive appliances, are the only means to offer relief in this incurable disease.

## ENTERITIS AND GASTRITIS SUCCESSFULLY TREATED WITH ERGOT.

BY ALEXANDER R. BEYER, M.D., OF BERKELEY, CAL.

ALTHOUGH completely retired from practice for several years, I had occasion, a few months ago, to see what I could do for a gentleman who had been suffering from chronic enteritis for more than four years. This was only one of the protean forms of gout to which he had long been a martyr; but it had persisted, with almost no interruptions, in spite of great and intelligent dietary care, and occasional attempts at specific treatment. In fact, the only interruptions during this long period occurred when the gout appeared "frankly" in one or both feet; but, on the other hand, this had been much less frequent since the enteritis set in than formerly. He had also many times suffered very distressingly from gastric catarrh and dilatation, and several times from acute gastritis.

At the time I speak of his appetite was fairly good, and gastric digestion was fairly well accomplished. But his bowels were in a condition to absorb his whole time and attention. Besides the pain, which was almost constant and frequently severe, and the dejections, which averaged from three to eight or nine daily, he suffered intolerable annoyance from flatulence. The various astringents, mineral acids, arsenic, milk, and lime-water, etc., had been fully tried, and I could find no fault with his very carefully arranged diet.

It was evident that the whole intestinal canal was excessively debilitated, and probably more or less dilated. He had also mitral disease, and dilatation of the heart, and had at times, although not very recently, suffered terribly from asthma. Was there not probably a general arterial debility? and might not *ergot* strike at the root of this trouble? As he is exceedingly susceptible to medicine, I ordered only  $\text{mxxx}$  of Squibb's fluid extract three times a day, and in a week his bowels were almost well, and have remained so ever since, requiring only an occasional Pil. Rhei. Comp. to prevent constipation. A week or ten days later, he had a very severe attack of gout in the left foot, lasting three weeks. Since then the gouty tendency has been kept down by Potass. Bicarb. (gr. v. in a glass of claret and water, with his lunch and dinner), and he has been more comfortable than for years.

So far, so good. There is nothing remarkable about the case, except the delightfully prompt and

perfect manner in which the medicine answered my hopes — I can hardly say my expectations.

But a few days ago I found that he had been overindulging his really hearty appetite during the holiday season, and had thereby brought about a severe attack of gastritis. Any food, however bland, brought on immediate and intense pain, which was only partially relieved when the food had left the stomach, which was already considerably dilated. (It is a fact, by the way, that he has developed what might be called gastric gymnastics, for, by lying upon the right side and contracting the abdominal muscles, — and he believes the muscular coat of the stomach itself, — he is able to force the food up from the depths of the dilated organ, and through the pyloric orifice; and he is made perfectly aware of the success of his efforts by the hot, burning, rasping pain, caused by the passage of the food through the inflamed orifice.) This condition had already lasted three days, and was becoming worse. I at once put him upon the *ergot* again, and in the same doses, and in forty-eight hours he was completely relieved, and able to bear a reasonable meal without discomfort.

From the previous experience, this is just what I fully and confidently expected. But I am led to report the case by the fact that I cannot find the least hint or suggestion of such an application of *ergot* in any book within my reach — even in such as treat fully of acute and chronic gastritis, and recommend (slightly and passingly) *ergot* in certain forms of chronic diarrhoea. My possibilities of reference, however, are limited here, and I have not the least ambition to claim priority in the matter, but I am anxious to draw the attention of physicians to a reasonable and probable remedy for this very painful and distressing condition, and beg them to experiment with, and report upon it. May it always — as in this one case — "work like a charm!"

## REPORT ON RECENT PROGRESS IN THORACIC DISEASE.

BY FREDERICK C. SHATTUCK, M.D.

### ACUTE PNEUMONIA.<sup>1</sup>

THE sub-committee to which the report on this subject was entrusted has analyzed and tabulated 1,065 cases of acute pneumonia as reported by 182 different observers in all parts of the United Kingdom. Drs. Sturges and Coupland furnish some remarks on the general conclusions which can be drawn from a study of these cases, from which the following is abstracted: —

"It must be admitted, in the first place, that much of the information elicited is of negative rather than positive value. We are unable to assert that the incidence of pneumonia is in harmony with that of any other acute or specific disease, while the fact that bronchial and catarrhal affections, speaking generally, are apt to concur with it, was known already. On the other hand, the evidence that such concurrence is by no means invariable, the frequency with which pneumonia attacks more than one member of a household at the same time, the

<sup>1</sup> The Collective Investigation Record, vol. II., July, 1884.

fact that when it is unusually prevalent its mortality is exceptionally low, and the rarity of enteric fever in any near association with it, are all observations of value. Similarly, the inquiry into sanitary conditions, although it may not satisfy preconceived ideas, seems to show: first, that defective drainage and sewer-gas poisoning may both cause and favor the spread of pneumonia; second, that the affection, when of this origin, is not of exceptional severity or high mortality. . . . "The high mortality of the disease in the intemperate is no new observation, but the facts before us would seem to show that alcoholic excess is not only an important factor in determining the issue of pneumonia, but that it is often of itself the actual exciting cause of the affection. It may be asserted, indeed, that pneumonia owning this origin is, at all ages, the most fatal form of the disease known to us." Next to alcoholic poisoning there is ground for believing that fatigue and mental depression are the most unfavorable vital conditions with which to meet the disease.

"That pneumonia is sometimes conveyed from person to person must, we think, be admitted, notwithstanding that some of the examples quoted to that effect are capable of other explanation. The sanitary conditions — in which, probably, ill-ventilation as well as defective drainage ought to be included — appear to favor such conveyance, and it would seem necessary that the intercourse should be intimate and prolonged, like that of patient and nurse or of bedfellow. In such circumstances, infectious pneumonia, we think, must be admitted as a reality — a rare characteristic of the disease, of which we are not, at present, in a position to offer an explanation. Yet, while admitting as much, it must be affirmed at the same time, that pneumonia, as we commonly see it, has no infectious character."

The list of previous diseases undergone by the subjects of pneumonia is very small if we exclude infantile diseases; but it is remarkable that one patient in every nine or ten had experienced a previous attack. This fact indicates that one attack predisposes to another, but recovery seems as likely to take place after a second as after a first attack. Only one case in sixty had the disease three times, and of these twenty-five per cent. died.

"In regard to the apex as a seat of pneumonia it is to be noticed: first, that this seat is as favorable for the patient as any other. (In the duration and mortality, indeed, it is more favorable than most.)

"Second, that no tendency is observable on the part of patients of phthisical family to exhibit pneumonia at this seat.

"Third, that in the exceptional event of an apex pneumonia occurring in a patient of phthisical family, such pneumonia shows no tendency to degenerate into phthisis, but undergoes resolution as quickly and completely as another. Thus the doctrine of the exceptional gravity of apex pneumonia finds no support in the Returns.

"There is another point which, equally with the one just noted, may demand notice, inasmuch as it conflicts with some accepted definitions of acute pneumonia. The proportion of sudden to gradual subsidence fails to bear out the statement that sudden remission of fever is the rule of the disease.

The only law that obtains in this regard is this: that when the pneumonic pyrexia has lasted over eight days its sudden subsidence is improbable, and that sudden subsidence after ten days is very rare. The favorite days for sudden subsidence are the fifth, sixth, seventh, and eighth, the seventh being far ahead of all the rest, and the fifth and sixth about equal. Crisis seems especially apt to occur in cases of apex pneumonia."

As regards sequelæ, in twenty cases chronic pneumonia resulted; but sequelæ of any kind are rare. Phthisical destruction occurred in but four cases, one, if not two, of these, having phthisis to start with, and two more, one a drunkard, died of gangrene of the lung. Pleurisy and empyema together are sequelæ in but thirteen instances. Death is most common on the sixth, seventh, eighth, and tenth days.

As regards the nature of the disease, in conclusion, it is stated: —

"Keeping clear of hypothesis, we believe that the following statement defines and comprehends the several forms of the affection which have to be recognized and find illustration in the present report: —

"(1) Of pneumonia as a local affection there are examples in plenty, especially in early life. Its onset is sudden, and due to some notable chill or exposure of the body; it has all the character of acute inflammation, with a marked tendency to spontaneous recovery, and is largely dependent on certain meteorological conditions, which are productive also of other forms of lung inflammation.

"(2) Distinguished from these are examples of secondary pneumonia, such as arise in the course of many acute and specific affections, and which do not, at present, concern us.

"(3) In addition to these two well-recognized forms of the disease, clinical observation, we think, bids us recognize a third variety — a pneumonia due to causes not directly injurious to the lung, but operating through the blood or nervous system. It, too, is properly a secondary pneumonia, for it is but the signal and expression of anterior vital changes; yet, owing to the absence (or the apparent absence) of any other organic lesion, it is not so accounted. Although anatomically indistinguishable (so far as we know at present) it deserves separate recognition in virtue as well as of its distinctive origin as of the fact that it has a variable rate of mortality, and a gravity which is not commensurate with the extent of lung tissue involved."

#### RELAPSING OR INTERMITTENT PNEUMONIA.

Sir Andrew Clark<sup>2</sup> reports the case of a man of eighty-two, who in 1877 went through an attack of pneumonia. In the spring of 1881, after exposure to cold, pneumonia developed at the right lung, and during the following seven weeks the patient passed through nine or ten severe rigors with six pneumonic consolidations, all portions of both lungs being invaded before recovery finally took place. The remarkable character, assemblage, and progression of the symptoms, and the age of the patient, make the case one of great rarity in the annals of medicine.

<sup>2</sup> *Lancet*, 1881, II, p. 1,492.

## TUBERCULOUS CROUPOUS LOBAR PNEUMONIA.

Kinnicutt<sup>3</sup> reports the case of a man of thirty-three who had never suffered from pulmonary disease, and who, three days before admission to hospital, had several sharp chills, followed by cough, expectoration, and fever. On admission the sputa were viscid, though not rusty, and the physical signs pointed to advancing pneumonia of the right upper lobe: solidification rapidly became complete, and, until the eighth or ninth day, the course of the disease corresponded with an attack of ordinary pneumonia. After the ninth day, however, the fever, pulse, and respiration, gradually increased, and the physical signs showed rapid disintegration of the solidified portion of the lung, evidences of a cavity being detected on the thirteenth day. On the sixteenth day after admission the patient died with the signs of general pulmonary oedema and heart failure. The sputa were examined for bacilli on the fourteenth day, but none were found. At the autopsy the solidification of the right upper lobe was verified; the cut surface was not granular, and numerous miliary tubercles were found near the periphery of the consolidated area as well as in the middle and upper portion of the lower lobe. Some of the alveoli were filled with pus and some with cheesy masses. The right upper lobe contained several cavities. Tubercles were not found in the other organs. The disease was correctly diagnosed several days before death. Dr. Kinnicutt refers to two similar cases reported by Sée to the French Academy of Medicine in 1883.

COLLECTIVE INVESTIGATION IN GERMANY.—PNEUMONIA EVENTUATING IN PHTHISIS.<sup>4</sup>

Eight of the fourteen cases returned are selected for analysis, the others being thrown out by the committee. In two of the eight pleural effusion complicated the pneumonia, phthisis following in one to two years. The other six cases are divided into two series of three each. In the first series the pneumonia, twice of the base, once of the apex, terminated by lysis, and, after an interval of several weeks, during which there was no fever, the temperature rose again and the signs of phthisis, rational as well as physical, began to appear. In the second series, all apex cases, there was lysis; but the temperature never reached and maintained the normal point, unmistakable signs of phthisis developing soon after.

## THE CONTAGIOUSNESS OF PHTHISIS.

Meyerhoff<sup>5</sup> furnishes the report on this subject and analyzes forty cases, in eleven of which the disease was communicated by the husband to the wife, and in twelve from the wife to the husband, the parents of the infected partners not having been phthisical in any case; indeed, of the whole twenty-three there were only three who had had any near relative consumptive. [The large proportion of cases in which the disease was taken by the husband from the wife is remarkable. Of cases hitherto reported the proportion has been much smaller, and the explanation which has been given would

seem satisfactory, namely, that the nursing of a sick man naturally devolves in great measure on his wife, whose other duties are also in the house, rather than outside of it, as is the case with men. The reporter is cognizant of a case in which he is satisfied that the husband contracted phthisis from his wife, she having the disease at the time of her marriage. The man had no hereditary predisposition to consumption and finally recovered entirely, some shortness of breath on exertion being the sole rational sign which he presented, and a number of years having elapsed since cough and expectoration ceased entirely. Rep.]

RECOVERY FROM PHTHISIS.<sup>6</sup>

Leyden and Fraentzel analyze fifty-seven cases, in twenty-two of which there was apparent hereditary predisposition. In thirty-four of the cases there was repeated hæmoptysis. Not to encumber our pages too much with figures, it may be stated that these cases, as far as they go, show that the same periods of life during which phthisis is most commonly developed also show the most recoveries; that hereditary predisposition is not of such evil omen as has been supposed; that repeated hæmoptysis occurs in about two thirds of the cases which recover; that even when both apices are attacked the patient may get well; that there is complete disappearance of all signs, both rational and physical, in only from one third to one fourth of the cases, though cough and expectoration had vanished in two thirds. In the great majority of cases there was no medication whatever, change of climate seeming to be the means of cure.

SYPHILITIC PHTHISIS<sup>7</sup>—DOES IT EXIST?

It has long been known that syphilis may attack the lungs; but a vast deal more has been heard of pulmonary syphilis since the question was broached whether the direct cause of the characteristic lesion of phthisis—caseation and cavity formation—may not sometimes be the venereal virus; that is to say, whether there is not also a syphilitic phthisis.

After a careful critical study of all the literature of the subject and also of three cases under his own observation, Hiller concludes that there is, as yet, no clear scientific proof of the existence of such an affection. In the reported cases of syphilitic phthisis sufficient evidence is lacking either of the destructive and ulcerating nature of the pulmonary process or of the syphilitic origin of the same. Those cases in which the diagnosis was apparently confirmed by the autopsy were really simply combinations of syphilis with either phthisical or bronchiectatic lesions.

The anatomical changes in the lung chargeable to syphilis are cicatrices, connective-tissue growth, gummatous, and chronic induration of the pulmonary tissue in the form of peri-bronchial growths, nodular formations, and diffuse lobular condensation, which generally start from the bronchus of the part (diffuse syphilitic infiltration).

The diagnosis of these changes during life may be made with a certain degree of probability at

times, but can never be made with certainty. The shortness of breath, cough, scanty and sometimes bloody expectoration, and other signs, rational as well as physical, are so wanting in characteristic peculiarities that the syphilitic nature of the affection cannot be made out from them. The diagnosis is to be based rather on the history of the case, the presence of the well-known symptoms of general syphilitic infection, and laryngoscopic examination, which will reveal in nearly all cases of pulmonary syphilis old lesions of the upper air-passages.

#### OBLITERATION OF THE THORACIC AORTA.\*

Dr. Hall White showed the specimen and reported the case before the Pathological Society. The patient was a man of forty-six, and the diagnosis of heart disease was made during life, the physical signs being a systolic bruit and some oedema of the lower extremities. "At the post-mortem examination the aorta was found to be so constricted at the point where the ductus arteriosus joins it, that it would only just admit an ordinary probe. The ductus arteriosus had completely disappeared. The aorta between the left subclavian artery and the constriction was so small that the subclavian artery appeared to be the direct continuation of it. The thoracic and abdominal aorta were very small. The collateral circulation was thus carried on: The superior intercostals were very large and convoluted and anastomosed with the first aortic intercostals, which were also very large; the posterior scapular arteries, both of which came from the third part of the subclavian artery, divided on the back of the upper border of the scapula into two branches which, reuniting, formed a circle on the back of that bone; from these posterior scapular arteries branches of great size were given off, which anastomosed with the second, third, and fourth intercostal arteries close to the spinal column; the right subscapular artery was extremely large and tortuous and divided into two branches, both of which joined the intercostal artery in the ninth space; the left subscapular artery joined the arteries of the ninth, tenth, and eleventh intercostal spaces; the internal mammary arteries anastomosed with the aortic intercostals, the phrenic arteries, and by their superior epigastric branches, which were very large and tortuous, with the deep epigastric arteries; the right superior epigastric gave a large branch, which descended in the suspensory ligament of the liver and anastomosed with the hepatic artery in the substance of the liver; small branches of the inferior thyroid artery anastomosed on the longus colli muscle with branches of the intercostal arteries; a descending branch of the profunda cervicis artery running down to the semi-spinalis muscle joined the posterior scapular arteries; the inferior thyroid artery on each side was a branch of the common carotid. The deformity in this case was, as it probably is in all of these cases, due to a faulty development of the fourth left branchial arch, which extends from the left subclavian artery to beyond the ductus arteriosus. The heart, which was also exhibited, showed extreme hypertrophy of both sides. All the cavities were much dilated, the dilatation keeping pace with the hypertrophy. In the

apex of the ventricular wall was a large patch of fibroid degeneration. It was pointed out how extremely rare the deformity was, very few cases having been recorded, and only one of these had been diagnosed during life. The age to which patients thus deformed lived varied very much, for one man lived to be ninety."

[In this connection it is of interest to refer to a case of occlusion of the superior vena cava in a man of seventy-two. The diagnosis was made during life and the full report of the case is to be found in this journal for January 22, 1885. Rep.]

#### CAFFEIN IN HEART DISEASE.

Riegel<sup>9</sup> after extended trial of this remedy and its preparation formulates his conclusions as follows:—

(1) Caffein is a heart regulator and diuretic in the same sense that digitalis is.

(2) Caffein in suitable dose and form increases the power of the heart, slows its action, and increases arterial tension, producing this effect soon after its administration.

(3) Caffein acts rapidly as a diuretic.

(4) The indications for the use of caffein are in general the same as those for the use of digitalis.

(5) Caffein is best administered in small and frequently repeated doses. In most cases one to one and a half grammes of the double salt daily is sufficient, though it is safer to begin with smaller doses.

(6) The main difference between the effect of caffein and that of digitalis is that the former is much more prompt and is not cumulative.

(7) In many cases in which digitalis fails, caffein will succeed.

(8) It is not advisable to give morphia at the same time with caffein; the latter, in that it restores the failing compensation, is practically a narcotic in these cases.

(9) Caffein, and especially its soluble double salts, sodio-caffein benzoate, salicylate, and cinnamylate, the solubility of which favors their subcutaneous use also, are, as a rule, better borne than is digitalis.

Becher's<sup>10</sup> results are not materially different from those of Riegel. Diuresis goes hand in hand with the tonic effect of the drug upon the heart, and this observer also found that caffein succeeds sometimes when digitalis fails. He does not seem to have used the double salts, but thinks that of the more common preparations the hydrobromate is less likely to make the patient wakeful.

#### ADONIS VERNALIS IN HEART DISEASE.

Altmann<sup>11</sup> has tried this drug, the use of which as a heart tonic was revived by Botkin, in a number of cases of valvular disease, with ruptured compensation, and also in cases of fatty heart, myocarditis, and parenchymatous nephritis with scanty urine. It is indicated where digitalis is, works more rapidly than that drug, is not cumulative, and often is

\*Lancet, 1884, II. 826.

efficient when digitalis fails. At the same time the author does not propose to give up the use of digitalis but seems inclined to restrict the use of adonis to cases in which the former does not prove efficacious. The method of administration was generally in an infusion of one part to thirty, of which he gave a teaspoonful every two hours.

In the discussion which followed the paper, Lublinski said that, judging from his experience, the cases are rare in which adonis is to be preferred to digitalis, to which remedy he was generally obliged to recur. The bitterness of adonis, which is very difficult to cover, is an objection to its use, and it may cause nausea, vomiting, and even diarrhoea. Diuresis without corresponding increase in the blood pressure is a remarkable effect of the remedy, and the specific gravity of the urine often reaches 1.022 or more, due to increased elimination of urates and chlorides.

#### A MODIFICATION OF THE BINAURAL STETHOSCOPE.

Dr. D. M. Cammann<sup>12</sup> has devised a new chest-piece which can be fitted to any ordinary double stethoscope, but of which it is not easy to give a clear idea without the aid of a wood-cut. The shaft near the chest-piece passes through a rubber bulb which is so connected with the surface to be applied to the chest that the air can be exhausted and the instrument held to the chest by suction.

The advantages claimed for the invention are intensification of the sounds produced within the chest and the liberation of both hands of the examiner who can thus practice auscultatory percussion.

The reporter on seeing Dr. Cammann's article sent immediately to New York for the chest-piece and has tested it upon a number of cases of thoracic disease; he has not been able to satisfy himself that the sounds are rendered either louder or clearer by this addition, which does, however, facilitate auscultatory percussion. The double stethoscope is sufficiently cumbersome to carry already without an addition the value of which is so very limited.

Dr. B. W. RICHARDSON, in an article on the "Painless extinction of life," in the current number of the *Popular Science Monthly*, says that in the method devised by him the mode of death to which the animals are subject is that by anaesthesia, not by suffocation or asphyxia. Death by anaesthesia is death by sleep; death by asphyxia is death by deprivation of air. Death by anaesthesia is typically represented in death by chloroform; death by asphyxia is typically represented in drowning, or in immersion in carbonic-acid gas. When properly carried out, death by anaesthesia is by far the most certain and least violent of the two processes, although both are probably painless. It is worthy of record, however, that all animals are not equally susceptible to the action of the narcotic vapors. Cats, for instance, lie asleep much longer than dogs before they cease to breathe. They fall into sleep as rapidly as dogs, but do not pass so quickly into the final sleep. There is a difference between different animals of the same kind.

## Reports of Societies.

### PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M.D., SECRETARY.

FEBRUARY 23, 1885. The President, Dr. F. W. DRAPER, in the chair.

#### CASES OF CONSERVATIVE SURGERY.

Dr. C. B. PORTER showed two patients. One had struck himself with an axe while felling trees; the blow extending across the foot from the great toe, dividing the soft tissues of the dorsum and all of the metacarpal bones excepting the fifth, as well as cutting a buttonhole in the sole. When seen by him there had been free bleeding and the extremity of the foot was tipped down from the tarsus. Treatment had been a posterior iron splint with a foot-rest, and a drainage-tube with antiseptic dressing. It is now eight weeks and three days since the accident and the patient will have a serviceable foot, flexing it from the ankle by the tibialis anticus which is strong, although there is no control by the extensors of the toes which were cut.

The other was a lad who by a machinery accident had the soft parts of the arm torn from their attachments to the humerus, with the exception of a small isthmus; the ends of the muscles being turned up and the bone being comminuted. On taking off two tourniquets, which the patient wore to the hospital, the radial pulse was felt, showing good circulation of the brachial artery; the ulnar and median nerves were intact, but the musculo-spiral was stripped of its surroundings for nearly five inches, and laid bare in the wound. After removing broken pieces of bone the muscles were placed in position by two strong catgut ligatures through each muscle, and the skin was stitched together. It is six weeks since the injury and there is practically an excision of the elbow-joint, the skin has not sloughed, and there is perfect control of the muscles supplied by the musculo-spiral. The arm is serviceable and will be more so as the inflammatory thickening passes off.

#### DISCUSSION OF THE BEST SANITARY AND THERAPEUTIC MEASURES FOR THE PREVENTION AND CONTROL OF EPIDEMIC CHOLERA.

Dr. S. H. DEXTER said that there are four factors in the prevention of cholera: Quarantine, cleanliness, isolation, and disinfection. Quarantine, he believed, might, and would, keep all infectious, exotic disease from the land, but to be secure it must be an absolute quarantine, such as no community would submit to. All persons and things must be detained at the port of entry or at the border long enough for the incubation period to pass. Means of purification must be used of course. The delay to commerce at every seaport and on the whole length of our northern and southern frontier would be intolerable. Unless it were enforced at all points business would seek those less guarded, to the commercial injury of the others, and the disease would enter just the same.

What may be called a reasonable quarantine is one against infected places, passengers and goods

from non-infected places being allowed to pass. This is now done at the large seaports of the United States, where it is comparatively easy. On the land border it is more easily evaded, and cholera may come to us, as it has done in the past, from Canada, over whose ports we have no control. Cleanliness, that is, the general principles of hygiene, must be observed. The speaker did not know of any general sanitary means employed against any contagious disease which was not, in his opinion, of service when employed against cholera. We need a clean city. Cholera develops more on one soil than on another, and if an epidemic occurs it is more severe in low, damp, dirty spots, than on high, clean, well-drained ground. The drainage of Boston is to-day fair. Although we are not yet entirely independent of the drainage of other places, the intercepting sewer has done much that it was intended to do. It makes a current in level sewers that were stagnant. Silting has disappeared and some saddle-backed sewers have been tapped at the lowest points and relieved of much filth. The condition of the water-supply is a matter of great importance. Our drinking-water, not always pleasant, has much improved and may still further. Well-water in a city is always liable to contamination, but our wells are fast disappearing, and the Board of Health hope that they will soon be things of the past. Careful inspection of food ought always to be insisted on, and it has been fairly done with us for years. Individual habits are of importance. There can be no doubt that intemperance and filthy habits predispose to the disease. Warm and suitable clothing should be worn inasmuch as chills undoubtedly cause diarrhoea, and the speaker thought that diarrhoea, fear, anger, cold, fatigue, and sleeplessness predispose to cholera. The belief is well-supported that a prevalence of diarrhoea has frequently preceded an epidemic, and it seems rational that the germ may develop in a disordered stomach and bowel, while it may be digested or neutralized in the intestinal canal in a state of health.

If in spite of quarantine and a clean city and individual cleanliness the disease nevertheless comes, then it must be fought by isolation and disinfection; and for this reason every case, and especially the early cases, should be at once reported to the Board of Health. There is a difference of opinion as to whether cases should be removed to hospitals. Dr. Durgin's own opinion is that there are few cholera patients who can be safely carried through the streets, either on their own account or that of others. Time is lost in the treatment, and there is danger of the profuse dejections being scattered about. He believes it unwise to move the very sick, except where isolation cannot be secured at home. It would be better to supply nurses and disinfectants to those who cannot get them otherwise, and as some patients must leave home, a number of district hospitals is preferable to a general cholera hospital. Isolation is of the utmost importance. Should an epidemic occur during warm weather he prefers properly floored tents to buildings, and the Board has asked for legislative authority to take land for the purpose.

Disinfectants will probably be supplied by the

city to the poor and will be sprinkled in the streets and gutters in case of an epidemic, also in vaults, although the Board mean to annihilate vaults and cesspools in the thickly occupied part of the city. They are unnecessary and honeycomb the ground with filth. Corrosive sublimate, chloride of zinc, and sulphurous acid are used by the Board as disinfectants. Corrosive sublimate has been used for a year and is the stronger and better. Importation of rags from any place without disinfection is prohibited by the general government. We shall have in a few days an apparatus now used in New York for forcing dry steam into a bale without unpacking it, by which the temperature is raised in less than a minute to 200°-300° F., and in less than four minutes to 500° F. Dr. Sternberg in New York reports that it is very efficient, although a single experiment with sulphurous acid applied in the same way has failed. The speaker had used sulphurous acid in Boston for eighteen years and has learned to have great confidence in it which he would be sorry to have destroyed. He has been in the habit of burning not less than two pounds of sulphur to 1,000 cu. feet tightly closed, and after this disinfection has not hesitated to equip convalescents from small-pox with the clothes worn by their less fortunate comrades of the hospital. He would do it again.

Dr. H. I. BOWDITCH referred to a recent paper of Dr. Vanderpoel, of New York, on this subject. He, Dr. Bowditch, thought that it ought to be the duty of consuls to telegraph the sailing of ships from cholera ports unless they had been thoroughly explored and found clean. It would be well if every physician in the country should write to his member of Congress on the subject. Everything should be done in advance without panic, and then if cholera comes we should isolate. He agrees with Dr. Durgin that where possible it is better to isolate in the house than to send to the hospital, also that the disease finds its home in filthy places. The city water-supply is filthy at its source and ought to be controlled at once, otherwise if the disease occurs at Natick we shall have it here. Nevertheless, Dr. Bowditch does not think we are to have a serious epidemic.

Dr. FRANCIS MINOT wished to emphasize Dr. Bowditch's remarks on our water. The people of Natick will not drink it themselves. They have a good supply from another source which they pass through their water-closets into our reservoirs. He hopes that cholera will not go to Natick.

Dr. H. W. WILLIAMS said that he was in Paris last summer and had never before seen it so clean. Communication with the infected districts of France was not cut off, but the epidemic was mild. He agrees with Dr. Durgin that it is desirable to have a careful inspection of food, and he thinks that it is a matter of public concern that our inspector of milk, upon whom we can thoroughly rely, should be kept in office.

Dr. J. G. BLAKE said that it is not easy to protect our water collected from a watershed of 72 square miles, in the face of a hostile Legislature. It is for the convenience of the country towns on the watershed to use it for drainage. Last year an effort made to compel another disposal of sewage

was vigorously opposed, and a suit against a Natick hotel-keeper for polluting water was defended by the town. The city, however, won at every step, and there is reason to hope that we may get a proper law on the subject. Much has been said of Peagan Brook. It is an example of what we want to abolish, and of what ought to be abolished. It has, however, been exaggerated. There are one hundred and fifty water-closets discharging into the brook, and the brook is filtered through charcoal and sand before entering the lake, which is three miles from the conduit. There is no current in the lake and it is doubtful if much of this filth gets into the city supply. Many factory owners on the Sudbury River have, at the request of the Water Board, made other arrangements for their filth, and we hope to soon have power to compel. The committee on drainage at the State House is largely made up of members from Framingham and the towns on the Sudbury. The matter has, however, lately been referred to the committee on health. The water is really in fairly good condition, yet if cholera should show itself on the watershed, the speaker would prefer to boil it or to get another supply if possible.

Dr. J. H. McCOLLUM spoke of a source of danger in the city prison under the Court House. Prisoners are there for but a short time, but it is foul, and cholera occurring there would have a tendency to extend. It would not be necessary for a patient to be there long to be very dangerous. In a former epidemic, the presence of a few emigrants at Suspension Bridge for a few hours was enough to give the disease a start at that place. Another source of danger is digging up the ground. There is reason to believe that large quantities of freshly turned soil favors the spread of cholera. Considering the cases at Toulon, reported at the last meeting by Dr. Shattuck, it would seem important to have a sanitary inspection of second-hand clothing-shops, which may be very dangerous, and which are certainly often offensive to passers-by.

In an Indian hospital, reported by Dr. Scudder, there was the difference between 10 per cent. and 20 per cent. of deaths in two similarly situated wards, but in one of which, the one with the smaller mortality, a small quantity of sulphurous acid, not enough to be offensive, was passed into the air constantly. In other respects treatment was the same as everywhere—heat, ice, morphia subcutaneously, etc. In the *Berliner Klinische Wochenschrift*, Dr. Lippert, after speaking of the pathological appearances, recommends rectal injections of opium and dilute disinfectants, in the hope of destroying the comma-bacillus.

Dr. J. C. WHITE said that he thought a quarantine, to be efficient, must be carried out by general rather than by local authorities. Otherwise there will certainly be a weak point somewhere and the restrictions will utterly fail of their object.

Dr. BOWBACH said that, so far as power goes, we have no national board of health; and that the surgeon-general of the Marine-Hospital service has announced that he will take no steps with regard to cholera until officially notified by the governor of a State that an epidemic exists.

Dr. DURGIN, in reply to Dr. White, said that

when a cargo was known or suspected to have come indirectly from an infected port, he would have it quarantined as if it had come directly. He also said that there is good reason to hope that the Board of Health is about to have power to close vaults. At present it can recommend their closure, but can only enforce their cleansing, which has, of course, only a temporary effect. The present committee on health of the Legislature is disposed to give the Board all the support needed.

Dr. R. H. FRZ entirely agreed with Dr. Durgin in his view of the practical impossibility of establishing an absolute quarantine. The importance of local measures in preventing the spread of cholera could not be too strongly emphasized. The earliest possible recognition of cases of the disease was, therefore, of prime importance, and the differential diagnosis between the early stages of cholera, cholera morbus, diarrhoea, and dysentery, during epidemics of the first, was admitted as often difficult and, at times, impossible.

In the light of Koch's researches, it seemed desirable that the medical inspectors of boards of health should be taught how to recognize the comma-bacillus. His statement of its constant presence in cases of cholera had met with such repeated confirmation in different places as to make its identification an important feature in the early diagnosis of doubtful cases of the disease. The training necessary for this purpose could be obtained in a few days by physicians likely to be selected as inspectors, and the preparation of the objects for examination would add but little to the labor of these officials.

Dr. GEORGE B. SHATTUCK thought the position of the comma-bacillus and its relation to cholera too little established and still too uncertain to justify our basing a differential diagnosis upon its presence or absence, or depending upon it for an early diagnosis. It is still premature to affirm that this bacillus is found in all cases of cholera, and is not found in any other disease. The English commission, just returning from India, has adopted, as the result of their labors, conclusions opposed, in important particulars, to those of Koch. One of these commissioners, at least, Dr. Klein, is an accomplished microscopist, and the commission deserve a hearing. Whatever we may think of the individual members of this commission as mycologists, the statement they have recently made, that the occupants of the buttes constantly drink the tank or pond water crowded with comma-bacilli with perfect impunity, is a simple question of fact easily proved or disproved, but which may well make us cautious as to our acceptance of the comma-bacillus as a causative or even pathognomonic cholera bacillus. Dr. Shattuck, in reply to a stricture by Dr. Fitz, said that, so far from wishing himself to weigh the evidence and decide the question, he suggested simply a suspension of judgment until the evidence was in and could be weighed.

Dr. WILLIAMS thought that the disease would be recognized by its symptoms in less time than by the microscope. The train of symptoms is markedly recognizable.

Dr. H. J. BIGELOW said that he thought the

suggestion of Dr. Fitz was in the right direction. He did not understand that Dr. Fitz expected the diagnosis to turn on the microscope. It is one piece of evidence to help in making a diagnosis which, in most cases, can be made without it. In a limited number it may be an important aid. We could not make arrangements for inspection to-night, but he had no doubt they would be made. He hopes and believes that we are not on the eve of a great epidemic, but to-night's discussion is important and valuable.

#### **PATHOLOGICAL SOCIETY OF PHILADELPHIA.**

THURSDAY evening, January 22, 1885. The President, DR. SHAKESPEARE, in the chair.

##### **TWO CASES OF NEVUS PIGMENTOSUS.**

presented by G. E. DE SCHWEINITZ, M.D.

The first of these specimens is one removed from the face of a patient by Dr. John Ashburst, in the University Hospital. The man was aged about forty years, and the tumor took its origin in an ordinary mole, which, under the stimulus either of external irritants or undue manipulation, grew into a slightly raised mass, with flattened top and constricted base. After Professor Ashburst had excised the growth I made a microscopical examination of it with the following result: The uppermost portion of the tumor is densely pigmented and the pigment is further seen to be of a brown or brownish-black color and contained in spindle or round cells or to exist as free nuclei and granules. These pigmented spindle cells sometimes are arranged so as to form the boundaries of alveoli, which are in their turn filled with moderately large unpigmented lymphoid cells. The base of the mass shows a small-cell infiltrate, enlarged sebaceous glands, and a massing of the epithelium of the part, forming the appearances of squamous epithelioma. Below the fat and subcutaneous tissue nothing abnormal presents. This growth may be classed, I think, as a hypertrophied mole, having an epitheliomatous base.

The second specimen was removed by Dr. Agnew from the back of a man, also a patient in the University Hospital. This tumor developed from a mole and grew as a papular-shaped excrescence above the surrounding skin level. Microscopic examination of the mass showed it, like the former one, to be composed of a densely pigmented tissue largely made up of spindle cells and free granules. Among the interstices of these were numerous blood channels filled with corpuscles. No malignant change at its base was noted and the surrounding skin was normal. Ziegler in his recent work on Pathology speaks of the not infrequent occurrence of melanotic and alveolar sarcoma in cellular warts and pigment spots, and certainly some parts of the specimens from the first case are strongly suggestive of a sarcomatous structure.

##### **URETHRAL POLYPI.**

presented by DR. DE SCHWEINITZ.

The specimens of urethral polypi were removed from a patient with the following history: Aged about thirty years, contracted gonorrhoea which was unusually stubborn and prolonged in its course.

The disease had lasted about five months when I first saw the patient. He was then suffering, on account of some imprudence, from a moderately sharp attack of cystitis. Having recovered from this and from the acute symptoms of the exacerbation which had probably caused the cystitis, he returned to his former condition of a drop or two of purulent discharge in the morning which no treatment seemed to relieve. Suspecting then that the long-standing discharge, the diminished calibre of the stream of urine, and the feeling of weight in the perineum might be due to a polypus, I explored the urethra with an improvised endoscope and found first two, and later these three, polypi, removed them, and had the satisfaction of seeing a cure follow this treatment. They were all situated within the first three inches of the urethra. I think, no doubt, these little tumors are papillomas and belong to the more common varieties of new growths which are seen in the male urethra. A rough examination of them with a pocket lens reveals quite nicely their dendritic formation. Tumors of the urethra, in the male at least, are usually stated to be of rare occurrence, although as Dr. William Belfield, of Chicago, has remarked they may not be so rare as is usually supposed as the urethra is seldom systematically examined upon the post-mortem table. Belfield himself in a series of seventy autopsies discovered two urethral tumors.

##### **SLIDES FROM AN ADENO-FIBROMA OF LACHRYMAL GLAND.**

presented by DR. DE SCHWEINITZ.

These sections were made from a tumor of the lachrymal gland which was removed by Dr. Agnew. The growth occurred in a young man; was of five years' duration and painless, having been situated in the upper and outer part of the orbit. The eye was sightless from atrophy of the optic nerve. The tumor, which was about the size of an English walnut, was surrounded by a dense fibrous capsule. The main body of the growth was composed of fibrous tissue through which the remains of the gland tissue are seen. The epithelium is in places in a state of proliferation, but apparently no formation has taken place which could be justly characterized as malignant. The tumor may be classed, I think, as a fibroma or adeno-fibroma of the lachrymal gland.

##### **SPECIMENS FROM EXCISION OF THE ASTRAGALUS FOR CARIES, ETC.**

presented by DR. C. B. NASHBIDE.

Elmer, aged nine and a half years, had for some years suffered from characteristic symptoms of strumous disease of the astragalus, the details of which it is unnecessary to give. Early in November, 1884, he began to have chills, severe pain in the ankle-joint, which now became swollen, hectic and profuse diarrhoea. Although I had never been able to detect dead bone by the probe, I felt convinced that an abscess—the result of carious bone—had ruptured into the previously only slightly diseased ankle-joint. I accordingly, under ether, examined the ankle-joint which I found contained a considerable quantity of very offensive pus, which communicated with a cavity lined with carious bone, situated between the astragalus and os calcis. I excised the

astragalus and scraped out the carious external malleolus, as well the roughened surfaces of the tibia. The boy has since done well.

DR. M. LONGSTRETH presented the following specimens, the notes of which with the discussion not having been placed in the recorder's hands as yet, will appear in print at a future time.

(1) A kidney preserved as to color and texture by ordinary illuminating gas. (2) Sarcoma of the femur removed by amputation by Dr. J. H. Brinton.

PYELONEPHRITIS AND CHRONIC PARENCHYMATOUS NEPHRITIS IN THE SAME PATIENT, COMPLICATING CYSTITIS.

presented by Dr. J. Tyson.

E. D., a prostitute, aged twenty-five years, white, was first admitted to the Philadelphia Hospital on September 10, 1883. She was at that time suffering from diarrhoea, and stated that she had previously passed blood—although apparently none was passed after admission. She had no symptoms which attracted attention to the urinary organs and no examination of the urine was made. The history of the case at present attainable does not show whether or not she had had contracted gonorrhoea. Her diarrhoea disappeared under treatment, but she regained strength slowly. She was discharged on October 4, 1883, apparently in fair health, but was readmitted on October 25, 1883. She now presented oedema of the legs and face, and an examination of the urine made about this time disclosed the presence of pus. She complained of pain in the lumbar region and in the head and was much debilitated. The treatment was directed to warding off a threatened uræmia. The dropsy disappeared, but her other symptoms progressively increased until death relieved her. She died with symptoms of uræmia. Autopsy, December 2, 1883. Nothing noteworthy in external appearance. Slight pleuritic adhesions; thoracic organs otherwise normal. Abdomen: peritoneum normal; liver normal; spleen not examined. Kidneys: left, typical large fatty organ; right, swollen to more than twice its normal size; when opened found to present a marked pyelonephritis with great distension of the pelvis, the calyces filled with pus—partly fluid and partly inspissated. Bladder was in a condition of chronic cystitis. Cause of death, pyelonephritis with large white kidney. Dr. Tyson said that the chief interest attaching to the specimens lay in the association of these two very opposite conditions, apparent pyelonephritis or suppurative interstitial nephritis with chronic parenchymatous nephritis. The former condition is a well-recognized result of cystitis, the latter not. Dr. Tyson had never before met these conditions in association. Usually as a result of a long-continued cystitis however induced, we have a suppurative nephritis of one or both kidneys, but never so far as he knew parenchymatous nephritis. He thought the most reasonable explanation of the association was that of coincidence. That there had existed previously, perhaps, a chronic parenchymatous nephritis; that upon this a cystitis had supervened, and upon this a pyelonephritis.

Dr. Tyson said that he would like to ask the members whether they had ever found association

of these two varieties of diseased kidneys with cystitis. Dr. Fornad thought that he had seen one such case, but there was no history. Dr. Osler said that the condition of this kidney is not infrequently met with in persons dying of intercurrent affections, and that he should not interpret the case as previous speakers had done. The kidney disease was probably of many years' duration, the cystitis was secondary to it, and the other kidney affected with parenchymatous nephritis had become subsequently diseased. It was well-known that the ordinary scrofulous kidney, with pus in the urine, etc., often lasts for many years, ending in general tuberculosis or inspissation of the pus. He would like to ask how long pus had been observed in the urine, the state of the bladder, and whether there was evidence of tuberculosis in the various organs.<sup>1</sup>

Dr. Tyson replied that he was in the possession of no definite facts as to the duration of pus in the urine. The case had only been under observation for three months, and certainly pus had been detected two months before her death.

THE NEW YORK COUNTY MEDICAL ASSOCIATION.

STATED meeting February 16, 1885.

THE PROTECTIVE TREATMENT OF OPEN WOUNDS.

DR. T. R. VANICK, of Jersey City, Surgeon-General of the State of New Jersey, read a paper on the above subject, which, he said, was designed to be supplementary to the paper which he read, in May last, before the Section of Surgery and Anatomy of the American Medical Association, on "Railroad injuries of the extremities, with observations on the site of amputation, and subsequent treatment of the stump." He remarked in the outset that if his views should appear to some to be sacrilegious, attacking as they did the very Lares and Penates of surgical authority, they are not the inspiration of a moment, but the settled convictions arising from long-continued clinical observation. In serious injuries the things that had to be contended against are: first, shock and hæmorrhage; second, sepsis; and from time immemorial it had been the aim of surgeons to minimize the dangers of the one source of trouble and to prevent the occurrence of the other. After the receipt of an injury the open stomata of the vessels offered a means of access for septic material, and the danger of serious results from this cause would be much greater than it really is, were it not that the vessels continue for some time to pour out considerable quantities of serum, which served to cleanse and protect the parts. When, however, this exudation from the vessels ceased, the patient was exposed to imminent danger of septic infection, unless some means are employed to protect him from it. Any method, therefore, which would hermetically seal the vessels without causing irritation to the parts, promptly after the receipt of the injury, would seem to completely fill the indication of preventing sepsis.

<sup>1</sup> Owing to unavoidable circumstances a portion of the discussion, in which various explanations differing from Dr. Osler's were given, has to be omitted.—Recorder.

Dr. Variek quoted from Holmes's Surgery, Sir James Paget's description of the appearances of an open wound, and then showed from Flint's Physiology that blood-serum contained all the principles found in the plasma, or *liquor sanguinis*, with exception of the fibrin. This serum, he continued, was largely albuminous, and it was the albumen that was directly consumed in the method of treatment to which he wished to call attention. On the coagulation of this element depended the success of the treatment, which was so marked that he had not met with a single case of septicæmia since he had adopted it. He would say in passing, also, that whatever success had attended the use of bichloride of mercury and carbolic acid was in reality due to their power of coagulating albumen.

There are, however, positive objections to the use of both these agents on account of the danger of their constitutional effects, as well as of their properties as local irritants. In regard to the bichloride he had heard of several cases in which marked tetanus was caused by it, and he then referred to the opening address of Sir Joseph Lister before the Medical Society of London, October 20, 1884, in which he related the case of a lady from whom he removed the mamma and cleaned out the axillary glands. Immediately over the wound was placed a piece of oiled silk which had been dipped in a 1 to 500 solution of corrosive sublimate; then, over this, sublimate gauze, and outside of all, an abundant eucalyptus dressing. The next day when the dressing was changed, it was found that under the oiled silk, exactly corresponding to its extent, the skin was highly irritated, and was covered with small vesicles. It was also found that the inner side of the arm, where there was no wound, was in the same state of intense irritation. "While this case showed," Sir Joseph remarked, "that in the sublimate we had an agent that might give very beautiful results, it also indicated that we were dealing with an edged tool, which, while it might do admirable work, was very apt to cut our fingers." (*British Medical Journal*, October 25, 1884.)

Having quoted from Bartholow some account of the local and constitutional effects of carbolic acid, Dr. Variek alluded to a large number of cases in the hands of both American and foreign surgeons in which the use of that agent was followed by fatal or dangerous consequences. Among these was one under the care of Dr. H. B. Sands at the New York Hospital in 1879, in which the patient had been subjected to the operation of amputation of the thigh for mummified fracture of the femur. For five days after the operation the urine was green in color; an effect due to the absorption by the wound of carbolic acid, and in accordance with Lister's methods. (*New York Medical Record*, vol. xx, p. 151.) At a meeting of the Clinical Society of London in May, 1879, Mr. A. Pearce Gould had reported a case of amputation at the hip-joint in which the patient died at the end of sixty-eight hours. At the autopsy all the veins of the left foot, leg, and thigh were found to be filled with black coagulum, which extended into the common iliac vein; the thrombosis being due, in his opinion, to carbolic-acid poisoning. All went well up to forty hours after the operation; when, suddenly

and coincidentally with the excretion of carbolic-acid urine, the fatal symptoms set in—symptoms which were not merely local and limited to the affected limb, but general. Among the other cases to which he referred were two nearly identical ones reported by Dr. Alfred C. Post at the New York Pathological Society, March 26, 1881, and by Dr. E. H. Bradford at the Boston Society for Medical Improvement, March 28, 1881. Both were in children suffering from large gluteal abscesses in connection with old hip-joint disease. In Dr. Bradford's case the abscess contained about eight ounces of sero-purulent fluid. Carbolic spray was played upon the limb during the incision; the abscess was hyper-distended with a solution of carbolic acid of a strength of 1 to 40. The patient recovered quickly from the ether, but in the following night was seized with obstinate vomiting, which persisted during the morning, but stopped at noon. It returned again in the night, and the following morning the child was in a feeble condition. The urine that was passed was tar-color, and death took place two days later, with symptoms of collapse. (*Boston Medical and Surgical Journal*, April 7, 1881.)

The method which he had adopted with so much success during the past six years involved simply the use of water that was heated to a temperature slightly below the boiling-point employed freely and continuously until all oozing had ceased. By this means a protective shield was formed over an open wound from autogenous material that was always available. It not only facilitated healing, but aided the heart's action by the transmission of heat, and thus tended to prevent shock. With a very large hospital experience, he had had no death from either primary or secondary shock in his practice since he had resorted to the treatment. Its merits were, briefly, as follows: (1) simplicity, (2) availability, (3) safety, and (4) invulnerability. In order to test the protective agency of albumen he had performed some simple experiments, the results of which he now proceeded to give. In each of a number of test-tubes, rendered absolutely clean, he placed, on the thirtieth of October, 1881, some freshly prepared beef-tea; covering half of them with simple linen and the other with linen coated with serum. Within twenty-four hours the beef-tea in half the tubes of the first series became milky and turbid, and within forty-eight hours that in all of them was loaded with bacteria and evidently undergoing the process of decomposition; while in all the tubes of the second series, which were submitted to the inspection of the members, the beef-tea was as limpid and apparently fresh as on the day, four months before, when it was placed in the tubes. On January 21, 1885, he had repeated the same experiments, and in all the tubes which were covered with linen coated with serum the beef-tea was again found to be in a state of perfect preservation.

The paper was discussed by Drs. William Detmold, J. W. S. Gouley, and C. S. Wood, and by the President. Dr. Detmold stated that throughout his professional career he had been accustomed to use a water-dressing for wounds, but he had not employed the hot water, as recommended by Dr. Variek. He was accustomed

to make use of a simple compress in the case of even the largest wound, and he was careful that it should not be wet enough to drip. Too much water he thought was injurious, as he had sometimes seen the skin macerated by the large quantity employed. It seemed to him that Dr. Varick had omitted one point, and that was, he had not shown that the water he used was hot enough to coagulate albumen. Neither had he proved that blood-serum without being exposed to heat would not have the same effect as serum that had been exposed to heat; and it was his own opinion that it would, for he believed that in the case of wounds the albumen would coagulate, or, rather, dry, without heat.

In his experience he had found that the parts where injuries are most likely to be followed by sepsis were the genital organs. It was a well-known fact that internal urethrotomy was a peculiarly dangerous operation, a great many cases proving fatal; while in external urethrotomy this was not the case. Yet in the latter the parts were exposed to the air, and therefore peculiarly susceptible to the access of so-called germs. In internal urethrotomy he thought that the danger arose from the fact that in the vicinity there were large vessels which did not readily contract, and much loose cellular tissue. He believed that pus could get into the veins without the agency of any germs, and was free to confess that he had not yet quite been converted to the germ theory. All through the prevalence of these new fashions of antiseptics and drainage-tubes he had always adhered to the old methods formerly in vogue. He had been brought up to consider that foreign bodies should always be removed, and he did not like the idea of adding a new source of irritation.

In reply to Dr. Detmold, Dr. Varick said that he was perhaps not fully prepared to answer the objection that had been brought up. Physiologists tell us that albumen remains fluid when outside of the body until coagulated by heat or some other agent having this power. When left to itself for a considerable time, however, it would desiccate, though not coagulate. But during the time that was necessary for this there was ample opportunity for the admission of any germs that might be in the vicinity, granting for the time being that there were such mischievous agencies in existence. The special point that he had made was that the albumen should be promptly coagulated, and the impervious film thus formed over the surfaces of the wound before the oozing had ceased from the vessels.

Dr. Gouley said that years ago he had been accustomed to apply a solution of chloride of zinc to the surfaces of all wounds, as recommended by Dr. Pincus, of Philadelphia; the object of which was exactly the same as that Dr. Varick now accomplished by his much simpler process. In his experience, however, the cases in which septic trouble was most likely to occur were those in which there had been very profuse hemorrhage. Like Dr. Detmold, he had not yet been converted to the germ theory, and he believed that excessive loss of blood was a much more important factor in the etiology of pyemia than any so-called germs. The pus, he thought, did not enter the veins from without, but occurred within the vessels

themselves from the disintegration of thrombi which had formed in them. In conclusion, Dr. Gouley said that he could not too strongly express his approbation of the forcible manner in which Dr. Varick had condemned the use of bichloride of mercury and carbolic acid. As to the latter, he firmly believed that more lives had been lost by it than could have been saved through its agency. All good surgeons were antiseptists, though they were not by any means all *Listerists*.

Dr. Woon, who had been a surgeon in the army during the late war, stated some of the impressions which he had received from his experience at that time. Depressing influences, such as wet weather, the effect of defeat, etc., seemed to him to be more potent causes of septic trouble than the lack of antiseptics, which were then unknown, and he believed that the results obtained by the surgeons were, all things being taken into consideration, as favorable as those now met with in these days of Listerism. Cleanliness, he thought, was the essence of antiseptics.

The President, Dr. LEAH, thought that one great source of danger was the decomposition of blood-corpuscles, which became swollen from endosmosis. By the formation of a film coating the wound, through the coagulating agency of hot water, as employed by the author of the paper, not only was the decomposition of the blood-corpuscles avoided, but the admission of germs from the atmosphere, the possibility of which many of the highest authorities of the day believed in, was prevented. Dr. Varick's success was indeed wonderful, and it was of all the more value to the profession from the fact that his experience was so immense. For a number of years he had been surgeon to two of the largest hospitals in the United States, in which acute surgery formed a very prominent feature.

Dr. VARICK, in closing the discussion, said that in his paper this evening the results which he had met with had been given only in a very general way. The statistics of his amputations were fully set forth in the paper which he read at the meeting of the American Medical Association in May last. They were all major operations, and mostly in cases of railroad injury. He had also performed some major amputations since that paper was prepared, and he would now refer for a moment to these, in connection with the others. From the middle of August, 1879, up to the date of the paper he had had at St. Francis Hospital, Jersey City, twenty-one such operations, and since then one primary amputation of the arm; making in all twenty-two, all of which were successful. At the Jersey City Hospital, during the period named, he had had seven operations, and since then four more, making eleven in all, of which one case proved fatal. This amputation was one of the thigh, and the patient, who was a broken-down tramp, died in the night from secondary hemorrhage. In private practice he had had up to the date of the paper three cases, and since then one. Of these four one died, but in this case the stump was doing perfectly well, and the real cause of death was valvular disease of the heart. There was thus a total of thirty-seven cases, with two deaths, which, he thought, was a pretty good showing for the method of treatment

adopted. His success, he believed, depended also on two other additional points, namely, making the amputation through sound tissue and keeping the stump clean.

That the hot-water treatment exerted a distinct protective influence against hospitalism he had met with several excellent illustrations in his experience. On one occasion, at the Jersey City Hospital, when the house was greatly crowded, and when there were several cases of puerperal fever in the lying-in wards, and nine or ten cases of erysipelas in the male wards, two cases of railroad injury, involving amputation of the thigh, were brought in. Yet both these patients made good recoveries, notwithstanding the exceedingly unfavorable influences to which they were exposed. Referring to Listerism, he said that it had been claimed that it was a system of cleanliness, but this he did not hesitate to deny. While he had seen enthusiastic Listerists shave the limb of a child four years of age, that no precaution might be omitted, he had also seen the most approved antiseptic dressing removed from a wound in the shape of a cup that was filled with the most offensive pus that he had ever met with in his life.

On motion of Dr. Detmold, a vote of thanks was given to Dr. Varick for his valuable paper.

#### THE NEW YORK ACADEMY OF MEDICINE.

STATED meeting February 19, 1885.

##### ELECTRICITY AS A STIMULUS IN CARDIAC AND RESPIRATORY FAILURE.

DR. GASPARD GRISWOLD read the paper of the evening, the object of which, he said, was to inquire how far the methods of applying electricity under the above conditions were in accordance with what is known of the physiology of the heart's action. In referring to the mechanism of the latter he stated that the accelerator nerves are opposed by the retarding action of the pneumogastric, which was always inhibitory. The accelerators increased the rate of the beats at the expense of force. To stimulate the heart, therefore, it would be necessary to apply the stimulus directly to the organ; but practically it was found that the application of electricity over the precordial region had an effect the reverse of stimulating. He then proceeded to narrate two cases which he thought very instructive. The first was reported in the *Philadelphia Medical Times* of June 1, 1881, and was one of death from cardiac failure after etherization. In addition to other measures resorted to, a faradic current was applied for a short time, with one pole to the neck and the other in the precordial region. The respiration remained comparatively unaffected, but the patient continued to sink, and died a little more than an hour after the anæsthetic had been withdrawn. The use of the battery in this case, he thought, might readily have caused the patient's death. The second case was one of poisoning by bitter almonds, which was reported in the *British Medical Journal* of July 2, 1881. When seen, the patient was quite insensible and collapsed; breathing gasping and labored; he was cyanotic; the pulse was hardly perceptible, rapid, and flicker-

ing, and the heart's apex-beat weak and rapid. The stomach-pump was at once used, and the stomach was then washed out with warm water, after which the patient became more collapsed, and his radial pulse almost ceased. The battery was employed for ten minutes,—twenty-five cells,—with one pole over the apex of the heart, and the other in the neck, over the course of the pneumogastric nerve. In twenty minutes liquor ammonie fortior was given as an inhalation, and the current applied as before, contact being made and broken with the inspirations. The battery and inhalations of ammonia were then continued alternately, at first every ten minutes and afterward every half-hour, for almost four hours. The patient's recovery was attributed mainly to the use of electricity, but Dr. Griswold thought that he recovered in spite of it, since the current from a battery of twenty-five cells would kill a large dog when applied to his pneumogastric, and that from six cells would cause faintness in human beings. The reason that the man was not killed by the treatment might be either because the battery was not in good order or else that the pneumogastric was so paralyzed by the hydrocyanic acid that it was incapable of responding to stimulus. That the man was paralyzed was indeed probable from the fact that three hours had elapsed between the eating of the bitter almonds and the application of the battery.

He then went on to say that it was rational to apply an electrical current in the neck in case of respiratory failure, since it had been repeatedly shown that stimulation of the phrenic nerve caused contraction of the diaphragm. Either a mild current could be applied continuously, or else one sufficiently strong to excite a deep inspiration be used momentarily, and the application be repeated at intervals of three or four minutes. But while this application of electricity undoubtedly stimulated the phrenic nerve, it also had the effect of stimulating the pneumogastric, and thus depressing the heart's action, unless the pneumogastric was paralyzed. The two nerves were so close together in the neck that under ordinary circumstances it was utterly impossible to stimulate the one without stimulating the other in addition. The function of the pneumogastric was to retard and even stop the heart's action, but in opium-poisoning this nerve was apt to be paralyzed, and hence electricity could be applied to the neck in this condition with a prospect of its affecting the phrenic nerve alone. He knew of one case of opium-poisoning, however, in which instant death was produced by the sudden application of a current in this locality for the purpose of stimulating the phrenic through the effect which it had upon the pneumogastric. Hence the following conclusions: (1) that electrical stimulation of the phrenic nerve was liable to stimulate the pneumogastric also; (2) that only mild currents should be employed; and (3) that especially should the sudden application of a strong current in the neck be avoided.

Dr. Griswold said that he had been induced to make an investigation of this subject in consequence of a case of his own in which a patient suffered from an overdose of tincture of aconite because the druggist who put up a prescription in which some aconite was ordered neglected to add the water

directed. It was advised by Dr. A. A. Smith, who saw the case in consultation, that electricity should be applied to the neck; but he opposed this measure on the ground that while the current might assist respiration by stimulating the phrenic nerve, it might have a dangerous effect upon the heart through the influence of the pneumogastric, which would also be stimulated. He then decided to make some experiments of his own on dogs. The first drug that he experimented with was aconite, and he found that when he applied an electrical current to the pneumogastric nerve of a dog under the influence of aconite the heart's action was not at all affected by it, while the effect on the heart was very marked, as shown by the cardiometer inserted in the carotid, under ordinary circumstances. Even when the current was increased to the full strength of the battery no effect whatever was produced upon the heart. The results of these experiments, he ascertained afterward, are in accordance with the observations of other investigators, and the deduction from them was that there was no danger from electricity in aconite-poisoning, and it was therefore perfectly safe to apply a current to the phrenic nerve. Consequently, he now believed that Dr. Smith had been right in advising its use in the case which he had described.

In dogs under the influence of chloroform he found that death was quickly produced by the application of electricity to the pneumogastric, and in one case the fatal effect was instantaneous, the heart stopping in diastole and never beating again. The deduction was that the pneumogastric retained its excitability in chloroform-poisoning, and it was, therefore, extremely dangerous to apply electricity to the neck in this condition. In asphyxiation by ether he found that the heart could stand stimulation of the pneumogastric as well as in health, and the deduction was, therefore, that it was safe to stimulate the phrenic nerve to a certain extent. In opium-poisoning, when well marked, the pneumogastric was paralyzed, and there was, therefore, less danger in stimulating that nerve in this condition than in health. When morphia was injected into a vein, however, he found that the case was different, and the deduction which he made from this experiment was that, when morphia was injected into a vein, the heart was easily depressed by the application of electricity to the pneumogastric. The general conclusions at which he arrived were:—

(1) That electricity cannot be applied clinically in such a way as to stimulate the heart, literally speaking.

(2) That the application of one pole to the neck and the other to the præcordial region stimulates the pneumogastric, and may kill.

(3) That the stimulation of the phrenic nerve necessarily involves the stimulation of the pneumogastric, on account of their proximity in the neck.

(4) That the liability to stimulate the pneumogastric is not great in aconite, ether, or opium poisoning, on account of the paralysis of that nerve caused by these drugs.

(5) That in heart failure from chloroform or the injection of morphia into a vein the application of electricity to the neck is strongly contra-indicated.

(6) That under no circumstances should a current strong enough to excite muscular contraction be applied suddenly over the neck.

Dr. ROCKWELL was the first to take part in the discussion which followed the reading of the paper. Theoretically he thought the views expressed by Dr. Grissold were correct; but practically it was not necessary to use electricity with so much caution as he would lead us to suppose. Brown-Séquard had urged with great emphasis the danger of applying electrical currents to the central nervous system through the pneumogastrics, but in actual practice it was not found that the disastrous consequences apprehended really followed such applications. Some authorities believed that the pneumogastric nerves on the two sides of the body had a somewhat different action; the one having more influence over respiration, the other more influence over the heart, and his own clinical observation had seemed to show that this view was probably correct. One of the most important things about the action of electricity, and one which was apparently very imperfectly understood, was its secondary influence; and as a matter of fact this agent had long been recognized as of special value in stimulating the respiratory rather than the cardiac function. In conclusion, Dr. Rockwell related a case of opium-poisoning in which electricity was employed for four hours. When first seen the patient had a pulse of 40, and the respirations were 10 to the minute. The first application of the faradic current to the phrenic nerve in the neck had a very excellent effect, the respirations at once becoming of normal frequency. The pulse also rallied, and for two hours the case seemed to be doing very well. At the end of that time, however, both the pulse and respiration began to fall, and gradually sank to exactly the state they were in when the patient was first seen. After four hours of constant effort a fatal result seemed imminent, and very little more was done to maintain the flagging powers of the patient. After a time, however, a reaction set in spontaneously, and the case recovered. The practical point that this example impressed upon us was that the use of electricity should be maintained as long as there was any breath left in the patient's body. Here undoubtedly the employment of the current for four hours had tired over the system, failing under the depressing effect of the narcotic poison, until nature had a chance to reassert her power.

Dr. FORDYCE BAKER spoke of the influence on the heart of chloroform as compared with that of ether, and said that while the latter was undoubtedly much the safer in surgical practice, there could be no question that chloroform was in every way better in obstetrical cases. The explanation seemed to him to be that in surgery the anæsthetic was given to anticipate suffering, while in midwifery it was given for the relief of pain already existing. He also maintained that the existence of organic disease of the heart was no contra-indication against the use of chloroform in obstetrical cases, but, on the contrary, that it was a positive indication to resort to the anæsthetic at an earlier period than usual. He believed that the administration of chloroform during labor had the effect of conserving the vital energies of the patient to an extent that

more than counterbalanced any depressing effect that the agent might have on the cardiac function.

Dr. AMIDON was glad that the author of the paper had had the courage to tear down the idol electricity from the throne which it had so long occupied; but he regretted that he had not stated what agents could be depended upon instead of electricity as stimulants in cases of respiratory and cardiac failure. Artificial respiration was a very powerful remedy that could always be tried with perfect safety, and he believed it to be a fact that in a very large proportion of cases the cardiac weakness was merely secondary to that of the respiratory function. Dr. ROCKWELL, it seemed to him, was inclined to regard too lightly the danger of applying currents to the neck, and this was no doubt because, being a specialist, he was thoroughly skilled in the use of electricity, while Dr. Griswold looked at the matter from the standpoint of the general practitioner. In the pressing circumstances attending the cases of chloroform or opium poisoning which physicians were called upon to attend, it was unquestionably true that electricity was rarely ever applied in an intelligent or judicious manner.

Dr. PUTZEL thought that however correct the physiological hypotheses of the author of the paper might be, the deductions based on experiments upon animals were inadmissible. No method, he said, had yet been devised by which electricity could be directly applied to the pneumogastric nerves in the human subject. Consequently, the best electrotherapeutists now spoke simply of galvanization of the neck. Moreover, he did not believe that this was by any means as dangerous as Dr. Griswold seemed to believe, and although he had himself repeatedly employed a battery of twenty-five cells in perfect order for this purpose, particularly in cases of exophthalmic goitre, he had never seen any change in the respiration or the heart's action produced by it. From a clinical standpoint he thought the subject was one which required a great deal more attention than it had hitherto received, so that physicians generally might be induced to learn how to apply the current with intelligence and discrimination.

Dr. CORNING said he rose to take exception to the statement made by the last speaker that it was impossible to apply faradization to the pneumogastrics, since he himself had devised a method by which this could be successfully accomplished. This was shown by the practical results that he had obtained, and he referred particularly to one case of exophthalmic goitre under his care, in which the pulse was reduced in twelve weeks from 110 to 80.

Dr. A. H. SMITH said that in opium-poisoning the great difficulty was respiratory failure, and the object of the physician was to restore this function to its normal character. It could not be denied that a full inspiration could usually be secured by the application of electricity to the phrenic nerve, and if this was repeated about sixteen times a minute it was apt to be followed by good results. There was often a strong temptation to apply the current more frequently in the hope of stimulating the respiratory function to the fullest extent, but the too frequent repetition was by all means to be avoided. When the respiration became more natural it would generally be found that the cardiac failure would also

begin to pass off. Electricity was also useful as a general stimulant in opium-poisoning. Flagellation was often injudiciously practised, and from the abuse of this there was liable to arise the added danger of shock.

The President, Dr. JACOB, stated that in former years he had used electricity a great deal in cases of cardiac and respiratory failure, such as were met with in opium-poisoning, but more particularly in the asphyxia of new-born children. He had found that if the current was used more or less continuously for any length of time, while at first these functions would be stimulated, the increased activity was afterward followed by paralysis; and that this effect was reached more speedily the closer to the phrenic and pneumogastric nerves he applied the electrical current. His experience taught him, therefore, that the best practical way of using the agent was not to confine the current to the nerves, but to apply it generally to the muscles. His method was to keep one electrode in contact with the body, and then momentarily touch the skin in various parts of the surface; and this was the plan he would also advise in opium-poisoning. The shock thus received by the patient was often sufficient to excite the respiratory function, and he quite agreed with Dr. Amidon in the opinion that cardiac failure was generally secondary to that of respiration. The electrode used for these general applications upon the surface should preferably be a faradic brush.

In closing the discussion, Dr. GRISWOLD remarked that in his paper he had endeavored to bring out three points. The first was that the heart could not be reached in such a way as to be stimulated efficiently and certainly. He would not have thought it necessary to lay any stress upon this had not the two cases to which he referred in the early part of his paper, which were both published in medical journals of the highest standing, led him to believe that such an opinion might be entertained to a certain extent among the profession. The second point was to call attention to the fact that the pneumogastric and phrenic nerves lay so closely together in the neck that the stimulation of one of them was impossible without that of the other also. In opium-poisoning, when the patient was well narcotized and the heart's action had become frequent, we could stimulate the pneumogastrics with impunity, on account of the paralysis from which they were suffering. In the case of instant death to which he had referred (an account of which he had received from Dr. Janeway, whom he had hoped to have present in order that he might make some remarks in regard to it), the pneumogastric had not yet become completely paralyzed at the time the current was suddenly applied to the neck. It was, therefore, confirmatory of the results shown by his own experiments on dogs; and he believed that the reason why more patients suffering from opium-poisoning were not killed by the application of strong currents to the neck was on account of the complete paralysis of the pneumogastric existing at the time. In chloroform-poisoning particularly, he believed it was best to rely principally on artificial respiration, which was safe and efficient, while stimulation of the phrenic nerve was not safe or efficient.

## THE GERM THEORY OF DISEASE IN ITS RELATION TO THERAPEUTICS.

If the views advocated in a recent editorial<sup>1</sup> prove sound, then an infectious disease may be defined as "a conflict between the subject who is smitten and a particular microorganism, which multiplies at his expense, appropriates his air and water, disintegrates his tissues, or poisons him by the decompositions which accompany its development."<sup>2</sup> Granting this definition (to which daily increasing knowledge lends support), the study of bacteria in general, and especially of the moribigenous bacteria, possesses a surpassing interest to every physician who is not content merely to plod along in the ancient but obscure, and often dangerous and perplexing, path of empiricism, but who looks for illumination from the new aetiology; for it is not too much to affirm that, as the causes of disease are understood, the triumph of therapeutics becomes more easy and more certain.

It has long been the reproach of the medical profession that therapeutics is not an exact science. In the light of the germ theory it might virtually become such, or at least approximately such, with respect to a large group of devastating diseases, consisting of many species, all comprehended under the one genus — *microphytic*. The art of the physician, in the presence of these diseases, will consist in the observance of a few simple rules: What is the nature of the epidemic or particular infectious disease under consideration, and is the causative parasite known? If so, all the recognized agents of the anti-parasitic medication must be brought into use to prevent the development and pullulation of the microbe. What can be accomplished by intelligent and watchful prophylaxis to stay the spread of the infection must first be done, and human habitations and persons protected by suitable aseptic means. Indeed, it is from prophylaxis or prevention that the first and probably the greatest services may be expected. It is needless to say that sanitary science has already taken long strides in this direction.

As for the unfortunates who may be proved to be actually suffering from the invasions of the parasite, the problem of the therapist will be still somewhat difficult of solution. How best to destroy the parasite, and not injure his patient? He may not be able to apply his germicides in quite as unobtrusive a manner to the living human organism as he would to infected barracks or emigrant ships; but this leading indication he will ever have in view, namely, to render the human environment of the moribigenous microbes as uncomfortable to them as possible, and to weaken and limit their powers of multiplication. In short, when once the cause is ascertained there can ever be but one leading therapeutic indication, namely, to destroy this causal agent, or attenuate as far as possible its influence in the economy. The resources of the physician will be enhanced by the practical discoveries of the chemist and the micro-biologist, and experimental physiology will effect for all rival systems of medication "proving" that cannot be gainsaid because of a strictly objective character.

In surgery and obstetrics it must be confessed that the germ theory has already won triumphs; it has almost revolutionized the treatment of wounds, the methods of performing hazardous and difficult surgical operations (especially on deep parts), and the mode of management of that formidable complication of the lying-in state, puerperal septicaemia. Although the specific microbes of surgical and puerperal infection are not known, or but partially known, the influence of bacteria of some baneful kind on septicæmic processes is none the less recognized, and the results of strict aseptic treatment, germicide sprays, germicide dressings, and absolute cleanliness are of the most brilliant kind. Under Listerian precautions, joints are opened with comparative impunity, resections are less timidly performed, abdominal sections and operations on the pleural cavity have ceased to be a terror, and ovariectomy is no longer the hazardous thing it once was; cases of septicaemia and purulent infection after operations, of surgical erysipelas and gangrene, are almost unknown in our hospitals. In obstetrics the success has been more complete still, if we may trust the reports from the lying-in hospitals of the great metropolitan cities of the Old World and the New which have adopted the antiseptic method; the statistics of Tarnier respecting the freedom from all puerperal diseases of the Maternité the past few years are especially gratifying; this old hospital once came near being abandoned on account of the prevalence of child-bed fevers which almost decimated its wards.<sup>3</sup> In short, action based on the assumption that the germ theory is true, has saved thousands of lives and prevented sickness and suffering in a much larger ratio.

How far comparative medicine has benefited by the labors of such men as Koch, Davaine, Pasteur,

<sup>1</sup> Page 111.

<sup>2</sup> Duclaux, *Ferments et Maladies*, Paris, 1882.

<sup>3</sup> *Lec. Phil-le-Bacillaire*, p. 26.

Toussaint, Detmold, and others, who have demonstrated the parasitic nature of anthrax, fowl cholera, swine plague, murrain, etc., it is at present impossible to say. A clearer knowledge has certainly been obtained of the best means of prevention and prophylaxis. The real value of Pasteur's protective inoculations is still under dispute, though Greenfield has confirmed Pasteur's discovery as to the immunity afforded certain animals by attenuated virus, and the French government, on recommendation of their scientific commission, has bestowed on Pasteur high honors and a liberal pension for (as is believed) having saved the cattle and sheep of France by the hundreds of thousands from the pestilential charbon.

Whether the therapeutic application to the human infectious diseases of a wider and more accurate acquaintance with the special morbid agents — supposing it to be finally proved that the *matrices morbi* of all these diseases be a *contagium vivum* — shall verify the old adage that "knowledge is power," it remains for the future to decide. As factors in the problem, climate, locality, food, all have a certain importance; it is also worthy of note, as pointed out by Bouchard, that most of our antipyretic medicaments are antiseptic and antiparasitic. Moreover, all these morbigenous bacteria are able to exist only within a narrow range of conditions. They are all anaerobic, that is, do not thrive, or they lose their morbigenous properties in the presence of free oxygen; on this fact Pasteur has based his principle of the attenuation of virus by repeated cultures. A simple change in the temperature of their surrounding medium is sometimes sufficient to destroy their activity. Thus fowls are refractory to charbon. The normal temperature of birds is higher than that of mammals, attaining 42° C. in the gallinaceæ. But experimentation shows that at this temperature the anthrax-bacillus ceases to manifest activity and to multiply. This increased temperature of the blood constitutes the one factor of the superior resistance of the bird to charbon.

What is true of charbon is true of all micro-organisms as far as their life history is known; a certain temperature is necessary, above or below which they cease to present active manifestations. As for the influence of climate, it is worthy of note that bacteria which infest the higher animals sometimes lose their fecundity by simple change of climate; thus European cattle transported to Algiers become refractory to anthrax. Sée, in his late work on "Bacillary Phtisis," devotes a long chapter to the discussion of altitudes at or above which microphytic life in general, and that of the tubercle-bacillus in particular, is compromised; these are the ideal climates for early phtisis.<sup>1</sup>

With regard to the question of pabulum in its relations to the life of the infective microbes, we

are very much in the dark; we know, however, enough to be assured that the nutritive conditions of their existence are very strict, that *healthy* tissues and blood seldom furnish the aliment they require, — hence one important factor of the resistance of the higher organisms to the invasion of the lower; that, moreover, a lowered condition of the vitality of the fluids and tissues is generally the immediate and necessary precursor of the occupation of these latter by the dangerous microorganisms; that, finally, their triumph under circumstances the most propitious to their nutritive activity is always brief, as though certain special organic compounds on which they depend were soon exhausted.

These considerations are sufficient to furnish hints as to the problems with which medicine and hygiene in the future will have to contend, provided the germ theory of the infectious diseases shall have established its right of empire.

#### THE DANGERS OF WATER-GAS.

CONSIDERED as a sanitary matter, the manufacture and use of water-gas for domestic purposes cannot be defended for a moment. On the contrary, every consideration of safety is opposed to the introduction of this dangerous agent into dwelling-houses and public buildings. The source of the danger lies in the relatively great amount of carbonic oxide which is left in the product of the process of converting steam into gas by its exposure to incandescent anthracite. As is well known, carbonic oxide is of all gaseous poisons the most lethal; it kills as surely, if not as quickly, as hydrocyanic acid, and to admit it to inhabited rooms as an illuminating agent, under even more than ordinary safeguards against leakage, is an experiment the risk of which cannot be denied.

These are trite sayings. Yet the energetic agents of speculative enterprises, eager to place their "plant" and to make money out of the dear public, will declare that there is no danger in water-gas worth mentioning. They catch the attention by emphasizing the economic side of the case, and by reiterating how cheaply they can supply the new article. They wish all statutory restrictions removed so that, in the name of economy, they may make and send through our streets and into our houses an illuminating gas containing thirty per cent., more or less, of carbonic oxide. They grow hilarious when their attention is called to the record of deaths by the accidental inhalation of the "improved" gas in cities which have surrendered to their persuasive overtures. They declare that the coal-gas ordinarily used for illuminating purposes contains carbonic oxide like their water-gas, but that no one thinks of going back to whale-oil or tallow-candles through any apprehensions on that account. In short, they sneer at all the cautions which impre-

<sup>1</sup> That is, at 800 metres. "It is," says Sée, "to this quality of *receptivité* of the atmosphere that elevated climates owe their anti-bacillary or prophylactic property."

judiced and unpurchased sanitary chemists have uttered since the composition of water-gas was first appreciated, and they, in effect, ask the people to take a catamount or a lioness into their laps to caress in place of the familiar domesticated animal which gives its name to the whole feline family. Sensible persons will hesitate before they try the experiment, and will choose rather to endure the gas they have than to fly to other gas four or five times more dangerous to life.

These reflections are suggested by a report of recent investigations made under the instructions and direction of the Massachusetts Board of Health, Lunacy, and Charity, by Professors Sedgwick and Nichols, of the Institute of Technology, in accordance with an order of the Massachusetts Legislature. The report, though only preliminary to a fuller exposition of the subject after further experiments have been made by the authors, is very convincing. After a general statement of the nature and composition of illuminating gas, of which "the only ingredient possessed of really toxic properties is carbonic oxide," this being "intensely poisonous," the report presents a summary of the conclusions to which the authors have been led by their experiments. Of these we give a condensed abstract:—

(1) Water-gas is decidedly more poisonous than coal-gas.

(2) An atmosphere containing a small percentage of coal-gas may be breathed many hours without serious effects, while an atmosphere containing the same amount of water-gas will be injurious and even fatal.

(3) On account of natural ventilation constantly going on in the rooms, thus permitting considerable diffusion, ordinary coal-gas, containing about seven per cent. of carbonic oxide, is not a source of serious danger; with water-gas, on the other hand, on account of the larger proportion (thirty per cent.) of carbonic oxide, the danger line is easy to reach. And it must not be inferred that a gas containing twice as much carbonic oxide as another is necessarily only twice as dangerous. Water-gas is not only in itself *more* poisonous than coal-gas, but is also far more likely to produce injurious effects from similar accidental causes.

(4) Dogs, cats, rabbits, and pigeons did not show any symptoms of poisoning after exposure for many hours to an atmosphere containing *one* per cent. of coal-gas, being apparently able to resist it almost indefinitely; but the same animals and birds when exposed, under the same conditions, to an atmosphere containing from one-half to one per cent. of the water-gas invariably showed marked symptoms of poisoning at the end of an hour and a half, and death generally resulted after from five to eight hours of exposure to an atmosphere containing not more than one per cent.

(5) If instead of comparing the effects of the same percentage of the two gases, we consider the

time necessary to cause poisoning by the use of the same quantities of gas under the same conditions, we find a contrast not less striking. With water-gas let into a closed chamber of known capacity (700 cubic feet) at the rate of six feet per hour, the animals under observation showed well-developed symptoms of poisoning in an hour and a half, and were all dead within eight hours. In a corresponding experiment with coal-gas, a similar set of animals presented symptoms from which recovery would have been possible, and even easy, had they been set free; after twenty-four hours of continuous exposure, one cat and one rabbit were dead, but the other animals (dogs, cats, and rabbits) were not even unconscious.

It cannot excite surprise that, after these results, the report should contain these words in its closing paragraph: "Our opinion, based upon experiments, is decidedly averse to the general distribution of the so-called water-gas." Earnestly solicitous to promote all measures for public health and to oppose the advance, insidious or open, of all projects having a contrary tendency, we commend these independent and trustworthy observations of Professors Sedgwick and Nichols to the attention of our legislatures, and hope none of them will be tempted by false doctrines or other considerations to rescind the wise provision which forbids the manufacture of gas containing more than ten per cent. of carbonic oxide.

#### PENNY DINNERS AND OVERPRESSURE.

PENNY dinners has succeeded school-overpressure as the burning topic of the hour among London philanthropists. At first sight there seems but little connection between the two subjects. But under the surface a common root for the two branches of social reformation may be seen to exist. Dr. Crichton Browne attacked the system of public education as imposing too severe a task on the brains of the scholars. Mr. Mundella, representing the administration of the schools, retorted in effect that there was no overpressure, but if there were, it was due, not to the weight of the tasks imposed, but to the inadequacy of the pupils' mental strength, which insufficiency was due to a lack of proper food. Those who sympathized with Mr. Mundella's view of the question have thereupon organized the penny-dinner movement, or, at least, adopted it and harnessed it to the public educational system. The ponderous enginery by which alone our English brethren like to accomplish their good works has been set in motion. Boards, committees, and sub-committees, with their list of titled names and honorary secretaries, have been organized, and the cry of "overpressure" is already nearly drowned by that of "underfeeding." Already more than fifty penny-dinner centres are either in

operation or in preparation in the city of London, and the movement is extending with the alacrity characteristic of new and fashionable philanthropies over other portions of the kingdom.

The meals are served in connection with the school session, often in the schoolroom itself. A certain number of free tickets are issued to such of the pupils as cannot raise the requisite penny, but in most cases the money is collected. In one instance the shrewd device is adopted of collecting the money for five days' dinners on Monday morning as an incentive to regular attendance of the pupils in order that they may profit by the meals that have already been paid for. It strikes one, however, that the family which is sufficiently "forehanded" to be able to make such a deposit for each of its children as this is likely to be able to feed them at home. The paramount desire of the teacher who devised the scheme just alluded to, to secure a full attendance as the *summum bonum*, is shown by his triumphant statement that in a particularly raw and cold week of midwinter the report of absentees was zero, although whooping-cough was quite prevalent among the scholars!

There is no doubt that the supporters of this movement do furnish for a net cost (the "plant" being supplied by donation) of less than a penny, to each of their patrons, a dish which contains a certain amount of nourishment. In a series of letters published in the *Sanitary Record* (January 15, 1885), a number of receipts are given which can be filled at an average cost per plate of less than a penny. These receipts, for the most part, reduce themselves to two great classes: first, a soup or stew, of which the composition and cost are fairly represented by the following example:—

12 lbs. ox-head at 3½d. . . . .	s. d.
6 " marrow-bones at 1d. . . . .	3 6
10 " carrots at ½d. . . . .	5
4 " turnips at ½d. . . . .	2
Four cabbages . . . . .	5
Sweet marjoram, 2½l. thyme, 2d. . . . .	1
Parsley, 2½l. leeks, ½d. . . . .	11
½ peck of fine oatmeal . . . . .	9
Salt and pepper . . . . .	3
	7 3
12 1-lb. loaves at 4½d. . . . .	4 3
	11 6

This makes sixty gallons of soup and feeds two hundred and forty children. Cost (including labor, &c.), 3.1 farthings per head. Second, a kind of roly-poly pudding, of which the following is a specimen:—

Flour, 1½ peck . . . . .	s. d.
Suet, 2½ lbs. . . . .	2 1
Jam, 2½ lbs. (half a 7-lb. jar) . . . . .	10
Baking-powder . . . . .	2
	1 9

This feeds seventy children or a still greater number of "infants." The first of these dishes is

substantially in character and, we think, in cost what has been furnished in years past (perhaps with undiscriminating bounty) to the poor in many of our large cities. As to the second, when we think of its introduction to the stomach of infancy, we can only say that the pendulum of reform is in danger of swinging back from underfeeding to overpressure.

One of the best points we have noticed in connection with this movement is that on one occasion the recipe for the soup was given as a dictation exercise to the girls, and they were advised to carry it into execution in their own homes. Doubtless, in the instruction of the poorer classes as to the economies of buying and preparing food, there is room for an excellent work. Mr. Edward Atkinson has recently shown that the average cost by actual experiment and tested accounts, strictly and accurately kept, of boarding and lodging fifty-nine women in a factory boarding-house was less than twenty cents a day, and the food was good and abundant—something more, we are sure, than soup and roly-poly suet puddings. The reform most urgently needed is that which will teach the poor classes how to prepare and place the penny dinner on their own tables, and see to it that they are able to earn the penny.

#### MEDICAL NOTES.

—Two or three cases have been reported in which cocaine has been used with good results for vaginismus. The temporary character of the anesthesia was yet sufficient to allow of impregnation, which had before been impossible.

—The Mary Fletcher Hospital of Burlington, Vermont, receives nearly \$200,000 by bequest of Miss Mary A. Fletcher, who has just died in that city. The bequest comprises nearly her whole estate.

—M. Vulpian, at a recent meeting of the Académie des Sciences, read a note from M. Germain Sée, on cardiac hypertrophy consequent on growth. The writer remarks that it frequently happens that growing youths, from fifteen to twenty, are subject to palpitation and constant headaches, accompanied by hypertrophied heart. The principal symptoms of this condition, are increased volume of the heart, recognized by percussion, a *heurt de soufflet* at the apex, and irregular pulse. M. Sée recognizes three forms of this affection: the tachycardic, with rapid pulse and violent palpitations; the dyspnoic, in which the respiration is difficult; and the cephalic type, in which the cerebral circulation is disturbed in consequence of hypertrophied heart. He believes this condition is entirely misunderstood, and often interpreted as anæmia or a nervous affection; he asserts that it is perfectly remediable, and is of opinion that "hypertrophy

from growth" ought not to be considered as a reason for exempting youths from military service, always provided that they follow a treatment and diet appropriate to their condition. M. Vulpian and M. Larrey were less certain that lads with hypertrophied hearts are fit to be soldiers.

—The medical fable of the Crow and the Country Doctor, lately published in the *JOURNAL*, has gone the rounds of the Medical Press. The January number of the *Indian Medical Gazette*, published in Calcutta, repeats it with due credit to the place of its original appearance.

—Dr. William Braithwaite, the founder of the "Retrospect" that bears his name, and which for many years has been so well known to the profession, and especially to members of the Massachusetts Medical Society, recently died in his seventy-eighth year.

#### PHILADELPHIA.

—Prof. J. M. Mallett, having been reelected to the chair of Chemistry in the University of Virginia, has decided to accept, and has therefore notified his colleagues of the Faculty at the Jefferson Medical College that he will resign his present position as Professor of Chemistry at the end of this session.

#### PROVIDENCE.

—The annual meeting of the Providence Medical Association was held in the Medical Library on Monday evening, March 2, 1885. Officers for the ensuing year were elected as follows: W. J. Burge, President. C. H. Leonard, Vice-President. Herbert Terry, Secretary. G. T. Swarts, Treasurer. Standing Committee: H. G. Miller, G. A. Pierce, G. W. Porter, G. D. Hersey, R. H. Carver. Committee on Reading-Room: H. G. Miller, G. D. Hersey, G. W. Porter.

### Correspondence.

#### ROLLER-SKATING.

Mrs. Editor. — An opportunity for "collective investigation" on a point of practical importance seems to me to exist at the present time in view of the discussion, so voluminous but so inconclusive and often so absurd, that has of late been going on in the daily press on the subject of roller-skating. Is it not time to collect individual experiences on the existence or non-existence of any well-defined symptoms coming under the cognizance of medical men, reasonably ascribable to roller-skating — not when carried to an *excess*, but, as every exercise should be conducted, in moderation? A recreation so widely practised should not be left to the random criticisms of the lay public, but facts either for or against its hygienic effect as a form of exercise should be carefully observed and recorded. In hope to learn some such facts, I remain, very truly,

QUESTIONER.

### Miscellany.

#### ADDISON'S DISEASE.

THE details of the post-mortem appearances and the microscopical condition in a case of Addison's disease are related by Professor Cacciola, of Padua (*London Medical Record*, January 15, 1885). The patient, a man-servant, thirty-five years of age, died a year and a half after the skin had begun to bronze. The discoloration, with muscular weakness, had steadily increased. Febrile attacks occurred from time to time, and the patient died in one, delirious and convulsed. After death, beyond a certain softness of the brain, the nervous system, including the brain, the spinal cord, and sympathetic nerve, was found absolutely normal. The semilunar ganglia and solar plexus especially were carefully examined. The supra-renal capsules, on the contrary, were greatly altered. They were enveloped in a mass of fat and fibrous tissue, closely adherent to them. Each capsule was about the size and shape of a hen's egg, and weighed about thirty-five grammes. On section, the organs were seen to consist of a thick fibrous capsule of lardaceous appearance and tendinous consistence, sending prolongations inward. Between these prolongations were caseous substance and calcareous masses. The fibrous capsule and septa consisted of a thick connective tissue, with accumulations of leucocytes in course of degeneration. The contents of the spaces between the septa were made up of albuminoid detritus and oil-globules. In the central portion of the fibrous mass the connective tissue was calcified. Schizomycetes were looked for without success, but it is especially mentioned that some fat-globules looked like Koch's bacilli colored by Weigert's method. There was little noteworthy amongst the other pathological conditions. There was, however, engorgement of the lymphatic follicles and of the agminated glands of the intestinal mucous membrane. The kidneys also were enlarged.

#### NOISE AS A FACTOR IN DISEASE.

The *British Medical Journal* has a word to say on the subject of noise in the sick-room, not merely as a nuisance, disturbing and irritating by its conscious effect, but as having a destructive effect on the nervous system of those who may not be conscious of the irritation.

Just as there are noises which may be too "loud" or too "acute" for the organ of hearing, that is, scientifically excessive in the numerical speed, or in the amplitude, of the vibrations they set up in the membrana tympani, the plate of the stapes, or the elements of the organ of Corti, so there are noises which are either absolutely or relatively injurious to the auditory centre in the sensorium, or to that superior centre of audition, which is situated in the cortical surface of the cerebrum. The destructive effects of noises such as those of an explosion, or a piercing shriek, are understood. It is to be regretted that the mischief too often done by sudden and unexpected, too long expected, or too exciting, or too distressing, noises acting on the brain proper, necessarily or unnecessarily, when perhaps the fault

is not so much in the noise as in the organ by which it is impressed, is not equally well recognized. There is reason to fear that critically fatal, or permanently destructive, injuries are wrought in too many cases of cerebral irritation, nervous excitability, or mental hyperaesthesia, without the knowledge of either patient or medical attendants, so insidious are the effects of these nerve-destroying agents, and so subtle are the processes by which they produce the most disastrous effects. The ticking of a clock, which may at first soothe by its monotony, will sometimes unconsciously become an excitant. Of all noises, those which are repeated at appreciable intervals are the most harmful, because they set up a rhythmical disturbance in the nervous centres, like the rhythmical contraction set up in an area of capillary vessels, by stimulation of surface acting reflexly on the vaso-motor system.

It is not improbable that a morbid flushing of the auditory centres at regular intervals is set up by rhythmically repeated noises, such as that of bells, particularly the "fairy" and "funeral" bells, or the ding-dong of the regulation three or five bells used for service purposes in urban and suburban districts. Another notably injurious form of noise is that which increases in intensity, as the sound of

approaching wheels. The sense of pain produced by this accumulating excitant is a significant indication of the injury this variety of noise works. Another and most destructive noise is that which occurs frequently but at uncertain periods, and which either keeps the centre in a perpetual state of expectancy, or subjects it to a series of successive shocks. The most notable variety of this class of noises is that which finds its typical embodiment in the shriek or prolonged howl of the locomotive whistle. In some neighborhoods, even the cat-call whistle constitutes a tormentor of the same kind acting in the way described. It is not simply that these noises worry and irritate, preventing or disturbing sleep—that is, the physiological rest of the brain. That would be bad enough, but the matter is worse by far than this; for, whereas disturbance set up in the brain by the ideational centres acting *ab initio*—that is, to the extent, and in the way, in which only ideation can be original—may be destructive, by interrupting the nutritive processes, the disturbance set up from without is much more powerful and injurious, not simply over-exciting the cerebral centre, but actually throwing them—mechanically as it were—into a morbid tumult.

## REPORTED MORTALITY FOR THE WEEK ENDING FEBRUARY 21, 1885.

Deaths reported 2,660; under five years of age 556; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers and diarrheal diseases) 335, lung diseases 484, consumption 326, diphtheria and croup 162, measles 47, scarlet fever 45, typhoid fever 40, diarrheal diseases 25, whooping-cough 21, malarial fever 19, cerebro-spinal meningitis 13, erysipelas 13, puerperal fever 9, typhus fever one. From typhoid fever, Philadelphia 23, New York and Boston four each, Chicago three, Lowell two, Brooklyn, New Orleans, Pittsburgh, and Fall River one each. From diarrheal diseases, New York 11, Brooklyn and Samarra three each, Boston two, Chicago, District of Columbia, Lowell, Cambridge, Holyoke, and Newton one each. From whooping-cough New York 7, Philadelphia four, Brooklyn three, District of Columbia two, Chicago, Boston, New Orleans, Pittsburgh, and Lawrence one each. From cerebro-spinal meningitis New York 6, Chicago two, Charleston, New Bedford, and Taunton one each. From erysipelas, Boston 4, New York and Chicago two each, Philadelphia, Brooklyn, New Orleans, Cambridge, Springfield, and New Bedford one each. From malarial fevers, New York 9, Brooklyn four, New Orleans three, Philadelphia, Chicago, and District of Columbia one each. From puerperal fever, New York, Brooklyn,

and Fall River two each, Philadelphia, New Orleans, and Nashville one each. In 110 cities and towns in Massachusetts, with an estimated population of 1,322,024 (estimated population of the State 1,355,104), the total death-rate for the week was 18.25 against 20.57 and 19.15 for the two preceding weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,906,446, for the week ending February 7th the death-rate was 21.8. Deaths reported 3,714; infants under one year of age 753; acute diseases of the respiratory organs (London) 421, whooping-cough 104, measles 53, scarlet fever 59, diphtheria 37, fever 24, diarrhoea 29, small-pox (London 41, Birmingham 3, Liverpool and Cardiff one each) 46.

The death-rates ranged from 15.1 in Birkenhead to 32.2 in Preston; Birmingham 24.5; Blackburn 26.4; Bradford 19.5; Hull 21.6; Leeds 20.2; Leicester 23.6; Liverpool 25.4; London 20.3; Manchester 20.1; Nottingham 21.3; Sheffield 16.7; Sunderland 26.6. In Edinburgh 20.9; Glasgow 30.2; Dublin 30.3.

For the week ending February 7th in the Swiss towns there were 35 deaths from lung diseases, consumption 27, diarrheal diseases 12, diphtheria and croup 9, measles 4, scarlet fever 2, whooping-cough 2, erysipelas 2, puerperal fever 2. The death-rates were: at Geneva 23.3; Zurich 30.7; Basle 23.4; Berne 32.8.

The meteorological record for the week ending February 21st, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Date.	Barom-eter.	Thermometer.			Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM FEBRUARY 21, 1885, TO FEBRUARY 27, 1885.

BENTLEY, EDWIN, major and surgeon. Relieved from further duty at Fort Clark, Texas, and assigned to duty as post surgeon, Fort Brown, Texas. S. O. 17, Department of Texas, February 16, 1885.

TAYLOR, M. E., captain and assistant surgeon. Assigned to duty at Fort Stanton, N. M., as post surgeon. S. O. 29, Department of Missouri, February 21, 1885.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE TWO WEEKS ENDING FEBRUARY 28, 1885.

BATTLE, K. P., assistant surgeon. To proceed to Pittsburgh, Pa., for temporary duty. February 19, 1885.

PERVANCE, GEORGE, surgeon. Granted leave of absence for one week. February 21, 1885.

KALLOCH, P. C., assistant surgeon. When relieved, to proceed to Pittsburgh, Pa., and assume charge. February 27, 1885.

WATKINS, J. H., assistant surgeon. To proceed to Savannah, Ga., and assume charge. February 21, 1885.

#### RESIGNATION.

HATH, W. H., passed assistant surgeon. Resignation accepted, as tendered, by the Secretary of the Treasury. February 11, 1885.

#### PROMOTION.

KALLOCH, P. C., assistant surgeon. Promoted and appointed passed assistant surgeon, by the Secretary of the Treasury, from March 1, 1885. February 19, 1885.

#### SOCIETY NOTICE.

SUFFOLK DISTRICT MEDICAL SOCIETY. — The *Section for Clinical Medicine, Pathology, and Hygiene* will meet at 19 Boylston Place, on Wednesday, March 11th, at 7.45 o'clock. Dr. V. Y. Bowditch will describe a case of "Traumatic Linear Atrophy" (E. Wilson). Dr. F. C. Shattuck will read a paper upon "A Case of Multiple Sarcoma of the Skin. — Treatment by Hypodermic Injection of Fowler's Solution. — Recovery."

A. N. BLODGETT, M.D., Secretary.

FORTY YEARS' EXPERIENCE IN MIDWIFERY.<sup>1</sup>

BY W. SYMINGTON BROWN, M.D., OF STONEHAM, MASS.

THE art of midwifery belongs to prehistoric times; the science of obstetrics is the latest recognized of all the ancient sciences. There is no branch of medicine which demands more skill, presence of mind, or justifiable daring than midwifery. It needs a man who can neither be overwhelmed by disaster nor unduly elated by success,—one who has the courage and honesty to do whatever is best for his patient, irrespective of consequences. Of such men no profession possesses a superfluity.

It is a strange fact, however, that only sixty years ago practitioners in midwifery were not admitted as Fellows to the College of Physicians, London, on the ground of inferiority, and the Royal College of Surgeons did not require candidates for its diploma to undergo an examination in obstetrics. This odium has nearly disappeared in our day, but a single item illustrative of its vestiges may be cited. I refer to the fact that the popular encyclopædias of our own day make no reference to the lives of prominent obstetricians, such as Smellie, Levret, or Naegele. Hundreds of insignificant names are recorded in Appleton's, Chambers's, and Johnson's Encyclopædias, but a profound genius like William Smellie—writer, teacher, inventor, and artist—is not even mentioned.

During a short visit to Scotland, in 1878, I met a lady, thirty-five years old, at whose birth I officiated obstetrically. And I had attended more than a hundred midwifery cases before that one. I wish I possessed a record of them all. While a medical student I served three years as assistant to the late Dr. James Paterson, Professor of Midwifery in the Andersonian University, and delivered many women among the destitute poor of Glasgow. During the last nineteen years I have kept a moderately full record. The whole number, dating from 1840, must exceed 2,000 cases.

In 1842 forceps were rarely used. It was a period of reaction, and many physicians entertained a strong prejudice against their employment, except in extreme cases. Dr. F. H. Ramsbotham, physician to the Royal Maternity Charity, London, in summing up the symptoms warranting recourse to the forceps says: "If the pains have entirely disappeared, if the strength is failing, the spirits sinking, the countenance becoming anxious, if the pulse be 120 or 140 in the minute, the tongue dry, brown, and raspy; if there have been two or three rigors; if there be green discharge; if the head have been locked for four hours, and made no progress for six or eight hours; if the patient be vomiting a dark, coffee-ground-like matter; if there be hurried breathing, delirium, or coldness of the extremities," *then* we may use the forceps,—before sending for the undertaker.

I recollect attending one case in Glasgow during a long-drawn-out week. The woman was very poor, and had been compelled during the whole period of gestation to sit from fifteen to eighteen hours a day,

winding pins, in order to earn a bare subsistence. There were no alarming symptoms, but the abdominal muscles seemed to be powerless. I sent for Dr. Paterson, and requested him to help her flagging powers with the forceps, but he declined to do so. The case did not come under any of Ramsbotham's excuses. At last the poor woman got tired of waiting; she sent for a doctor with fewer scruples, and was instrumentally delivered. This case made a deep impression on my mind, and, in fact, converted me to the faith which I hold to-day.

In this paper I propose to state very briefly the principal conclusions I have arrived at under six heads, namely: Forceps, Turning, Ergot, Anæsthetics, Antiseptics, and Craniotomy. Before doing so, however, allow me to make one remark in regard to the language employed. Although what follows may appear like laying down the law in a somewhat curt fashion, such is not my intention. What follows are simply my own opinions on certain obstetrical problems colored by the personal medium. Nobody is more anxious than I am to be set right where I have been wrong. The late Dr. John C. Warren, in his classical work on "Tumors," gives us this good advice: "He [the surgeon] must get the opinion of other surgeons. Even those who have not so much experience as himself may afford him excellent hints, and strike out from his own mind thoughts which without this collision would not have been elicited." Dr. Barnes also truly asserts that "there is no man whose experience is so great that nothing is left for him to learn from the experience of others." Such societies as this one answer that purpose.

## FORCEPS.

I prefer curved to straight forceps. They are about as easily applied, and are less liable to slip. If a beginner can only afford one it should be a long pair, either nickel or silver plated. But it is convenient to own a short pair, and I always carry one in my obstetrical bag, along with a No. 6 gum-elastic catheter (male), a Davidson syringe, a hypodermic syringe, a few feet of flat, covered wire (such as milliners use), ether, ergot, eldoral, and whiskey.

The short forceps may be used at any time when their employment will benefit the patient or her coming child. We should not use them merely to save our own time. But the long forceps (when applied within the uterus) should seldom or never be used without a consultation. Indeed, it is a wise precaution, in most difficult or dangerous cases, to call in a brother practitioner to share the responsibility. I make it an invariable rule to pass a soft catheter into the bladder before applying forceps. In some cases using the catheter helps progress, even when forceps are not needed. If the rectum contains solid feces I also give an enema of warm soap-suds.

How should the forceps be applied? In Scotland the woman is placed on her left side, with her hips projecting from the bed. In this country the dorsal position is preferred, and it is the one I most frequently use. Lately I have tried a new way, which has certain advantages. The woman lies on her back, in the centre of the bed or anywhere, and is not moved at all. Of course, it is not convenient

<sup>1</sup> Read before the Obstetrical Section of the Suffolk District Medical Society, January 21, 1885.

to use long forceps in this position; but, when practicable, it avoids the appearance of preparing for a surgical operation, and I think the less fuss we make the better it is for our patient.

In most cases I insert each blade at the sides of the pelvis, without regard to the position of the child's head. If the vertex presents, you can scarcely go wrong by following this rule, and it saves the patient the annoyance of searching for an ear and other irritating manipulations. I make traction only during a pain, and relax pressure when the pain abates. I think it is advisable to pull with a slight pendulum motion, instead of using direct traction, on the same principle that it is easier to pull down a pair of tight pantaloons by drawing on alternate sides than by pulling on both sides at once.

#### ERGOT.

As a means of shortening labor ergot is seldom employed nowadays. The forceps have crowded it out of use for that purpose. But as an agent in promoting uterine contraction, after delivery of the placenta, and especially in cases of threatened flooding (some women have a hæmorrhagic idiosyncrasy), it is a valuable remedy. One reason why ergot has fallen into disrepute is the poor quality of many specimens offered for sale. Dr. Squibb's aqueous extract rarely disappoints me. It should be borne in mind, however, that no drug is readily absorbed during extreme depression.

After much blood has been lost our main reliance should be placed on other agencies, such as injections of very hot water and mechanical pressure. The accoucheur's hand inside the womb, with external counter-pressure, is the most reliable method. In milder cases I have succeeded in arresting severe hæmorrhage by injecting hot water and vinegar into the flaccid uterus. But the water must have a temperature of at least 130° F. in the basin, as it cools during its passage along the tube.

#### TURNING.

As this operation requires no surgical instrument, it obviously antedates the forceps, and, since the days of Ambrose Pare, has been a favorite with many practitioners, and even with skilled midwives. I was acquainted with a physician who, if one might draw an inference from his usual practice, seemed to think that nature had made a mistake in placing the child upside down in the womb. In our own day the late Sir James Simpson, Dr. Barnes, and Dr. Braxton Hicks have done much to bring version into favorable notice. On one occasion, before labor had fairly commenced, while making an external examination, I detected the child's head above the brim, and succeeded in converting a cross presentation into a normal one by the Braxton-Hicks method. I was agreeably surprised at the ease with which the change was effected. But, notwithstanding the plausible arguments advanced by Simpson, Barnes, and others, I have come to the conclusion that turning, after the evacuation of the liquor amnii, is a very dangerous operation for the child, and not much safer for the mother. I admit that cases occur where no other alternative (except Cæsarean section) is left us. If we conclude to turn, the operator's left hand should be used, and,

in most cases, it is better to bring down one foot than two feet. The accoucheur's left hand is the obstetrical hand *par excellence*. Physicians should learn to use it adroitly more than they do.

#### ANÆSTHETICS.

The foremost question under this head is, Do anæsthetics injure the patient? I am pretty sure that they do not. Since 1849 I have used ether, chloroform, or a mixture of the two with alcohol, in every case where the woman was willing to breathe an anæsthetic. Some object; they are afraid to take it, and these I do not urge; but the majority are glad to get it before the labor is over. As a general rule I do not give ether during the first stage.

High authorities tell us that there is a greater tendency to post-partum hæmorrhage after ether or chloroform has been administered. During the last sixteen years I have not employed chloroform in midwifery practice, except as a remedy for convulsions; but I believe that ether, in moderate doses, does not tend to bring on flooding. Ether is seldom given to the extent of unconsciousness. The patient knows what is going on, and can render voluntary assistance when solicited.

A small dose of ether acts beneficially in two ways: it blunts sensibility to pain and allows the abdominal muscles to aid in propulsion. Without ether the patient's will-power is instinctively exerted to delay the labor; with it, the canal is more likely to be relaxed, and the voluntary muscles are not so much restrained. The contractile power of the womb itself is not affected by moderate inhalation of ether.

#### ANTISEPTICS.

Cleanliness is a good thing in midwifery, and antiseptics are its aides-de-camp. A young doctor who keeps his nails in mourning will eventually have to mourn the absence of a lucrative practice. Still it is possible to have too much of a good thing. Dr. Thomas, of New York, has recently taken a stand on this subject which most physicians would call ultra. The rules and regulations he lays down might possibly be enforced in a hospital, but hardly in private practice. And even if they could be carried out, I question the advantage of trying to surround a physiological process with all the paraphernalia needed in a surgical operation. Carbolic acid has had its flood-tide, and begins to ebb. Corrosive sublimate will probably follow suit at no distant day. Please observe, I do not object to disinfectants or antiseptics in themselves. Both of the chemicals mentioned will, no doubt, be used occasionally with advantage. But I believe that carbolic acid nearly killed Dr. Thomas Keith, and not a few unfortunate patients have suffered from its wholesale reckless employment. I greatly prefer a weak solution of iodine, prepared with iodide of potassium, which may be diluted with water without precipitation, or a hot solution of permanganate of potass. In ordinary cases absolute cleanliness is all that is needed. The routine employment of vaginal injections is likely to do more harm than good. I concur in the opinions expressed by Dr. Adams, of Framingham, in his interesting paper read at your last meeting. Dr. Wm. Goodell's suggestion that lying-in women should be encouraged to

assume the erect posture early, with a view to facilitate the removal of clots and *débris*, is an excellent one.

As already hinted, it is a good plan for the obstetrician to wash his hands, keep his finger-nails pared pretty close, and to fill the small remaining space with softened soap before making a vaginal examination. A Syracuse aesthetic M.D. kindly suggests that no harm would result if he also washed his hands afterward.

#### CRANIOTOMY.

During the last nineteen years I have performed craniotomy three times, all of the cases occurring in the practice of other physicians. No operation tries a surgeon's nerve more than this one. When we are sure that the child is dead, of course it is plain sailing. But there are cases where the fetal heart cannot be distinctly heard, and yet the child is alive. To plunge a perforator into a living child's skull, and deliberately take its life, with a view to save that of its mother, is, to say the least, a sad alternative. I hope I shall never feel compelled to do it again. In these days of successful abdominal surgery, would we not be justified in appealing to the patient to allow us to perform the Cesarean section or laparoclytomy? But we should not wait until the woman is at death's door before operating. In this, as in all other life-saving operations, promptness and decision win the day.

The medical profession is deeply indebted to Dr. Thomas for his efforts to popularize laparoclytomy. I understand that he tried the operation several times on the cadaver before performing it on a patient. Nearly all great surgeons have been in the habit of doing this. In this case the principal difficulty will be to get the consent of the patient and her friends in season to be of any service. We all love to put off the evil day, or even the evil hour, and so the golden opportunity slips through our fingers. But as successful results in this line increase, the dread of the operation itself will decrease, and obstetric surgery may achieve a new triumph in the salvation of human life.

#### THREE CASES OF PELVIC HÆMATOCELE. —ONE DEATH.

BY M. A. MORRIS, M.D.

On the twenty-third of August, 1876, I first saw Mrs. R., twenty-three years of age, whose previous history was as follows: She had two children, one four, and the other five years of age. In labor she had been attended by an irregular practitioner, and had suffered from "womb trouble" ever since. She first menstruated at the age of thirteen, and had always been regular, the flow continuing three days, and never attended by pain. She had suffered from "inflammation of the bowels."

On the fourth of August her catamenia appeared as usual, but a *watery discharge* had continued up to the time of my visit. On the 17th she had an attack of severe pain in the right iliac region, and soon after, while conversing with a neighbor, she fainted, and fell from her chair to the floor.

Afterward she vomited, and noticed a slight show from the vagina. Four days later, although weak, losing color, and suffering some pain, she felt well enough to start on an excursion down the harbor. When the steamer was reached the pain became suddenly worse, and again she fainted and vomited. She was placed on a mattress and sent home, suffering the most terrible agony. On her arrival a physician was sent for, who gave her an opiate, which, with two doses taken on the way from the boat, relieved her.

I found her in bed, looking very pale, with a pulse of 96, and a normal temperature. There was vomiting, thirst, headache, painful micturition, and rumbling of the bowels,—the abdomen was somewhat swollen, tympanitic, and tender to pressure. Pain over the uterus was complained of, and on examination per vaginam the organ was found to be fixed, somewhat retroverted, enlarged, and tender. The os was sufficiently open to admit the tip of the finger. There was an indistinct feeling of fluctuation above, to the left of the uterus, and the fundus could not be felt through the abdominal wall. She thought she could not be pregnant.

Opium in sufficient quantity to quiet pain was given, and a mixture containing dilute sulphuric acid.

September 1st the flowing had stopped for four or five days, and then returned. September 4th there was barely a sign of flowing, and she was so comfortable that a sound was carefully passed into the uterus, showing its depth to be a little over two and a half inches, and that it was retroverted and displaced to the right. The external os and cervix were sufficiently open to easily admit the finger as far as the internal os. September 8th, with the hand on the abdomen and a finger in the vagina, a mass, perhaps as big as a large orange, could be felt to the left of the uterus. Pressure upon it caused pain, which could be felt in the liver and back. There was a scanty serous flow from the vagina, faintly tinged with blood. Micturition and defecation were still painful. She slowly improved from this time, and the tumor gradually disappeared. She was in bed seven weeks, and was quite well in three months. Four months after the beginning of her illness I made an examination, but found no trace of the tumor, and the uterus was free and movable. I think the hæmorrhage took place into the peritoneal cavity, in this case, as the pain was so severe and the shock so great. The fact that there was no circumscribed tumor at first, and that later on the mass became encysted, and had a well-defined outline, also points to its having been peritoneal. Treatment: Opium, poultices, and dilute sulphuric acid.

The second patient was thirty-three years of age, the mother of three children, the youngest three years old. She had been in good health and regular in her monthly periods up to two months previous, but since that time she had not menstruated. She always suffered from dysmenorrhœa. On the sixteenth of March, 1877, after eating a hearty breakfast, she began work at the wash-tub, and, soon after lifting a heavy tub, experienced severe pain in the abdomen over the uterus, and then a frequent desire to urinate. There was also a feeling of faint-

<sup>1</sup> Read before the Obstetrical Section, Suffolk District Medical Society, January 24, 1885.

ness, which obliged her to lie down. After a time the pain extended up along the right side to the region of the liver, and across the abdomen in the course of the transverse colon. At 3:30 p.m., when first seen by me, she was in bed, lying upon her left side and back, with the legs drawn up. It was difficult to induce her to lie upon her back for an examination, as the slightest motion increased the pain to a degree that was unbearable. Thinking that the heavy meal which she had eaten was the cause of her distress, she had a very large dose of tincture of rhubarb, which had not operated at the time of my visit.

The abdomen was normal in appearance. The pulse 80, the temperature 98.2° F. The pain following the course of the colon, and the attack following a hearty meal, consisting of some indigestible articles, the case was at first supposed to be one of colic, and an opiate was given to relieve it. Five hours later pain was also complained of in the back and lower extremities, the face and lips were very pale, and the surface of the body and extremities was cold, and there was faintness, thirst, and great prostration; the pulse was 120, and very feeble; the abdomen was swollen and tympanitic, but not tender on pressure. The cathartic had produced many loose watery dejections in such quick succession that she was unable to control them long enough to have a bed-pan placed under her. There was no flowing. The case now presented all the symptoms of a profuse hemorrhage, but there was such an enormous loss of serum and water from the bowels that in the absence of external signs of bleeding it was supposed that the symptoms were due to hypercatharsis.

Full doses of morphia were given to check the flow from the bowels, and she was stimulated with an abundance of brandy and carbonate of ammonia; heaters and blankets were applied about the body and to the extremities. It certainly seemed as if she could live but a short time; however, reaction took place, and the diarrhoea was checked. On the following morning she had a temperature of 102.2° F., a small and feeble pulse of 110, and quick breathing. The abdomen was much swollen, tympanitic, and tender; the pain was less, owing to full doses of the opiate, and there was some flowing. On passing my finger into the vagina I found the uterus movable, but the parts about it and the roof of the pelvis were tender.

On the 18th there was some vomiting and retention of urine, so that the catheter had to be used twice daily. The condition of the abdomen was unchanged. During the next six days she continued to suffer from severe peritonitis, and I began to think that there might be a hæmatocele. The temperature at this time ranged between 102.2 and 101° F., and the pulse between 120 and 132; it was not necessary to use the catheter, and the abdominal symptoms were less severe. On the thirty-first of March the abdomen was almost normal in size above a line drawn transversely through the umbilicus, but below that line it was swollen and flat on percussion. As the tympanitis had subsided, a tumor could now be felt extending half way to the umbilicus, occupying the epigastric and most of both iliac regions; the uterus was fixed, and a hard, irreg-

ular mass could be felt in Douglas's fossa, extending high up and behind it, and pressing upon the rectum. All the parts were tender about the roof of the pelvis, and the metrorrhagia still continued. The bowels, which had been constipated, now became loose, and several copious watery dejections were passed.

March 5th the tumor extended to within two inches of the umbilicus, and was tender on pressure; there was a projection from each side of it extending into the iliac regions, the mass on the right being the larger of the two. She urinated five or six times a day, and had a good deal of pain during the act.

At this time, as she was so debilitated and uncomfortable from vomiting, dysuria, and diarrhoea, all of which seemed to be due to the pressure of the tumor, and as it was rapidly increasing in size, and showed no tendency to point in vagina, rectum, or abdominal wall, and as there was also danger of its emptying its contents into the peritoneal cavity, I decided to empty it, if possible, by means of the aspirator.

April 6th. Pulse 112, temperature 99° F., respiration 28. A small needle was passed into the tumor two inches below the umbilicus on the median line, and nearly three pints of dark fluid blood, which had a strong odor of sulphuretted hydrogen, were withdrawn. Much relief was experienced from the operation. The pulse remained at 112.

April 9th. Pulse 96. Patient comfortable.

April 11th. Pulse 88; respiration 20; temperature not recorded. Urinates without pain; bowels regular; tumor enlarging.

April 13th. Pulse 84; respiration 20; temperature 98.2° F.

April 17th. Pulse 124; respiration 28; temperature 103.2° F. Frequent vomiting; flowing freely. Uterus is low down in the pelvis, and firmly fixed. A hard, irregular mass is felt in Douglas's fossa. By examination through the rectum a tumor, which was irregular in outline, tender on pressure, was to be felt. Externally it could be made out half an inch below umbilicus. Another pint of bloody fluid, a little thinner than molasses, and fetid like the first that was withdrawn, was removed.

April 18th. Pulse 108; respiration 20; temperature 100° F. No pain or vomiting. Slight soreness of puncture.

April 19th. Pulse 104; temperature 100.2° F.; respiration 24. Three ounces of very thick fluid removed.

April 23d. Two ounces removed.

April 24th. Pulse 100; temperature 101.2° F. Tumor has been gradually diminishing.

April 28th. Uterus movable. Sound entered two and a half inches. Only a small amount of fluid was obtained at this tapping, and she continued to improve steadily.

May 17th. She was sitting up, and expressed herself as feeling well.

June 22d. I found her about the house attending to her duties. In this case I fully realized from the time of the second visit that my patient had peritonitis, but did not think of hæmatocele as a possible cause of the symptoms till about the fourth day. I attributed the hemorrhage to a rupture of

some dilated vessels, probably in one of the broad ligaments. She had passed one menstrual period, and it was about the time she expected to be unwell that this accident occurred, so the vessels of the genital organs were in a state of congestion favoring the rupture which occurred when she lifted the tub. The treatment employed was opium in sufficient quantity to quiet the bowels and relieve the pain, digitalis and quinine to lower the temperature and pulse. Equal parts of oil of turpentine and olive oil were applied to the abdomen under hot flaxseed poultices. She took stimulants freely, and a diet of milk and yolk of egg.

On December 30, 1884, I was called to Mrs. T., aged thirty. She had four children, the youngest one year old, whom she was nursing. She first menstruated at the age of fourteen, and has regularly since, the flow always lasting four or five days. She never had dysmenorrhea. Notwithstanding that she was nursing she had menstruated regularly during the past four or five months. On December 23d she was surprised to find that her courses had come on just one week before the regular time. She had some pain in the groins and over the uterus, but paid little attention to it. On the 24th she went to the city in the snow and wet to do some shopping, and the snow moistened her feet and legs. The pain gradually increased, but was relieved by hot drinks and applications of hot water to the abdomen on her return home, at which time she noticed the flow had ceased. On the 25th she attended to her household duties, and was quite well. From the 26th to the 29th she kept about the house, but complained of a feeling of weight in the pelvis and rectum, and of pains in the abdomen, which she attributed to wind, as her bowels rumbled and the pains shifted about. I found her in bed on her back, complaining of pains all over the abdomen, which was somewhat swollen and tympanitic. The pain was most severe over the uterus, and to relieve it I ordered one fourth of a grain of morphia at once, then one eighth every hour till the pain was stopped. Her pulse and temperature were normal. On the following morning I found that three eighths of a grain of morphia had relieved her, and advised light diet, bismuth of soda before meals, and rest in bed. On the following morning she got up, ate some cold meat and an apple, and soon after vomited. The pain became very severe, and she grew pale, and complained of great thirst and faintness. In the evening I was called again, and found her pulse 76, and the skin cold and pale. She complained of dyspnea, great thirst, and frequent micturition, and in a few moments fainted, but soon recovered. The pulse was then 110. She complained of dimness of vision, and said that her pains were over the uterus and a little to the left of the middle line, and were like those of "womb colic." She could not turn on her back for an examination, as it increased the pain and made her faint. I introduced my finger into the vagina, and found the uterus quite high in the pelvis; the os was slit on both sides and open; there was no flowing. The body of the womb could not be felt, and the whole cervix was obliterated, and nothing but a ridge around the os to show its situation. The spaces in front of, and posterior to, the uterus were pushed

down, and had a soft, fluctuating feel. When I found she was not having a miscarriage, I made a diagnosis of pelvic hæmatocele. Opium, stimulants, and dilute sulphuric acid were given. In the evening her pulse was 144 and very small, and she had great difficulty in breathing. She said she could not see. She was covered with cold perspiration, and her urine was passed frequently. About twelve o'clock that night she died, apparently from the hæmorrhage.

An autopsy was granted on condition that a small opening only would be made to determine the nature of the case. A tumor, taking its origin in the pelvis behind and to the left of the uterus, could be seen. It gradually enlarged, and, spreading out as it left the pelvis, it extended more than half way to the umbilicus. It was attached by very soft, recent adhesions to the peritoneum, on the left of the abdomen, over a space about two inches square, and the greater omentum (lower border) was attached to the top of it. The tumor was punctured, and found to contain blood. The cause of death being evident, the friends did not allow the autopsy to be carried further.

#### VAGINAL DOUCHES. — ABDOMINAL AND VAGINAL COILS. — RUBBER TUBING CONTAINING BRASS WIRE SPIRAL.<sup>1</sup>

BY M. L. CHAMBERLAIN, M.D.,  
Visiting Physician to Carney Hospital.

THE use of hot vaginal injections has revolutionized the treatment of chronic uterine diseases. Since their introduction into medical practice more women are cured, and more made comfortable during convalescence, than ever before. No remedy, no elaboration of treatment, can show the restorative effects that are now constantly observed from the long-continued, regular application of hot water to the pelvic circulation through the vagina.

I will not enumerate all the various conditions and chronic diseases that are generally treated in this manner, but simply say that regular douches of thirty to forty minutes' duration, twice daily, continued for several months, will reestablish the uterine circulation to an amazing degree; and a continuous douche of several hours will act often-times as a wet blanket to prevent the ignition of inflammatory fires in the cellular tissue after exhaustive examinations, instrumental interference, and after replacing a wayward uterus.

According to Emmet, no procedure will so surely prevent cellulitis in pelvic hæmatocele, and assist in the absorption of the clot.

As given at present it is doubtful if we get the full benefit from douches that we ought. A tin pail or rubber bag, holding from four to eight quarts, is suspended above the level of the body, so that the liquid it contains will pass through the vagina in twenty or thirty minutes. During the first ten minutes the radiation of heat reduces the temperature of the douche-fluid four or five degrees in a room with the thermometer at 67° F. Every ten

<sup>1</sup> Read before the Obstetrical Section of the Suffolk District Medical Society, January 21, 1885.

minutes after it loses two or three points, so that at the end of thirty minutes the loss is ten to twelve degrees. In a chamber where douches are usually taken, the temperature is often under 60°, and the loss is greater. I filled a zinc douche-pail, having a cover, and holding at least two gallons, with water at the temperature of 114°, and allowed it to run out through the tube in nine minutes. I found that the water had lost eight degrees of heat in that time. A douche of the temperature of 100° to 105° has no special value as a remedial agent. If the douche-pail has no attachment whereby the temperature of the fluid can be kept at an even heat, the nozzle should be open enough to allow the water to pass rapidly, and an assistant should refill the pail with water of the desired temperature as often as necessary.

Vaginal douches are given in chronic uterine diseases to constrict the bloodvessels, so as to reinstate the debilitated and defective pelvic circulation, and to produce a salutary contraction of the uterine fibres. To obtain these effects most perfectly, it seems to me that the fluid should be released above the os, so that the cul-de-sacs and the neck of the uterus, at the vaginal attachments, may receive the full benefit of the hot water. To meet these conditions I have devised a hard-rubber nozzle, the upper end of which resembles somewhat the bowl of an ordinary spoon. When introduced the bowl readily seeks the posterior cul-de-sac. The water makes its exit in a continuous sheet from the upper segment, and by rotating the nozzle the whole neck of the uterus and the cul-de-sacs are brought thoroughly under treatment. This does away also with the danger of uterine colic, inseparably connected with the vaginal douche when given with the ordinary nozzle, which parts with the water below the os.

Some of us believe in using the vaginal douche in all cases of obstetrics. Nearly all believe it useful when chills, followed by rising temperature and offensive lochia, indicate that auto-infection is imminent, or is already taking place. Leaving out the question of intra-uterine injections in these conditions, we will confine ourselves to vaginal injections only. It is the custom to order the douche repeated every four to six hours, and perhaps, in some cases, every two hours.

It has seemed to me that washing away an offensive and poisonous discharge intermittently scarcely insures complete antisepsis. If vaginal injections are worth anything in these pathological cases, they should be continuous. One chief essential in giving douches to a parturient woman is that no force shall be imparted to the stream of water. I have observed that after parturition the vagina is nearly perpendicular, when the body is horizontal, and therefore a feeble current must obviously wash mainly the upper segment of the vagina, and leave the bottom of the vaginal well uncleaned; while, if force is used, the poisonous lochia and possibly deadly air may be carried into the cavity of the womb. If it is true, and I believe it is, that the posterior cul-de-sac is the most dangerous point to leave uncleaned, barring rents in the vagina, then the douche-fluid should be released in that spot *when fresh*, having lost none of its

disinfecting power. By this means we make sure that the current will be *upward and outward*, compelling an onward and precluding a backward flow of the lochia, which will be quickly and safely floated out of the vagina. To guarantee such a cleaning of the posterior cul-de-sac I have devised this *vaginal coil*, the mechanism of which I will describe in a few moments.

I think that a continuous or an occasional douche can be given a parturient woman through this coil without force, without air, and therefore *without danger*; and that the fluid will be delivered where it will do the most good. The coil is self-retaining, and can be left in the vagina any length of time without distress or discomfort, even if there is severe inflammation; and to avoid repeated insertions, which are always disagreeable and often painful when a nozzle is used, I leave the coil *in situ* just as long as the patient needs douches, and has not passed out of the stage of convalescence.

#### DESCRIPTION OF APPARATUS.

The complete apparatus which I show to-night consists of a reservoir, abdominal and vaginal coils, and a rubber bed-pan. The reservoir is made of copper, has a thermometer, a brass stopcock with a tin strainer to prevent particles from entering and occluding the coils, and a tin alcohol-lamp. The coils are made of pure rubber tubing, one eighth of an inch in diameter, containing a fine brass wire spiral. The latter prevents the tube from collapsing and allows it to be twisted, tied in knots, coiled or braided into any desired shapes without interfering at all with its patency. The physician or surgeon with fifty or sixty feet of this tubing and a silk fishline can make abdominal, chest, throat, cephalic, perineal, knee-pan coils or a fever mattress, to supply heat or cold to any parts of the body. He can fasten a piece of muslin to one end for a strainer, and drop it into an elevated improvised reservoir of ice-water, and coil as much as necessary around a leg or arm, and by gravity keep up a continuous application of cold; or can irrigate a wound in a similar manner with hot, warm, or cool water. The presence of the wire spiral in the tubing prevents any collapse of the coil by pressure of the body. At the same time the brass wire is so delicate that it adds no appreciable amount to the weight of the apparatus.

The abdominal coil is made by coiling around a central point about sixty feet of the tubing when green; the subsequent vulcanizing process fastens the coils together into a round, smooth, flexible mat, eleven inches in diameter by one eighth of an inch in thickness (the diameter of the tubing), weighing

less than seven ounces empty, and only eight and one-quarter ounces when full of water. It has affluent and effluent tubes, each four feet in length. The water emerges from the outlet in a stream or in rapid drops according to the height of the reservoir, and the temperature of the coil may be kept easily at any point of the thermometer desired. It can be used alone, or in combination with the vaginal coil.

The vaginal coil is made by taking two feet of the same material when green, coiling one end once and a half around into a circle two and one-eighth inches in diameter; the half-circle is laid upon the full circle where it is fastened by the vulcanizing process. The entire circle, only, contains the wire spiral; this forms a delicate spring which adapts itself, without apparent pressure, to the vaginal walls, and makes the coil self-retaining. When in position the coil usually surrounds the uterine neck, the outlet being in the posterior cul-de-sac. The stem emerging from the vagina is tied in a large loose knot which, resting on the pubes, allows the patient entire freedom of motion; it is then fastened by a safety-pin to a bandage around the abdomen. An inch from the end is a metallic cut-off. To give occasional douches by fountain or Davidson syringe, it is a simple matter to couple the smaller nozzles of either to the stem of the coil, under water, after pressing out the air from the inch of stem above the cut-off. Or connected with the reservoir by four feet of tubing, the coil gives a continuous vaginal douche with a minimum of trouble. Heat to the abdomen and hot carbolized water to the vagina can be given simultaneously, and for any length of time, by coupling the vaginal, to the outlet of the abdominal, coil and attaching the affluent tube of the latter to the reservoir.

This tiddle-shaped bed-pan differs from the ordinary rubber one in two or three points. The cushion is filled with water instead of being inflated with air, which makes it quite comfortable for a patient should it be necessary for her to remain on the pan for a length of time. The outlet tube is longer and larger, and the upper end, where it connects with the bed-pan, contains a hard-rubber perforated tube, five inches in length, that is removable for cleansing purposes; this prevents clots from entering and obstructing the flow of water through the outlet tube.

I first used the coils in November. I was called to a lady who had a moderate uterine hemorrhage of a foetid odor; a very tender abdomen, with severe continuous pain just above the pubes, and a pulse of 120 and temperature of 103° F. She did not think she had been pregnant, although she had passed two periods, but had been unwell two weeks previous to my visit. Before examination I found the uterus in a state of high inflammation, a large swollen neck with widely open external os, while the internal os grasped a pulsatious mass, which proved to be a placenta. I removed all that was in reach, gave a carbohc douche, and prescribed morphia, ergot, and digitalis, the latter on account of a mitral lesion which upon stress always developed an ugly pulse. Upon the next visit the patient was much in the same condition. I very carefully cleaned out the cavity of the womb with a wire curette, and, not thinking an intra-uterine

injection advisable, I washed out the cervical canal with a carbohc douche, and continued the same internal treatment. I also directed that she should have large hot vaginal douches, the last pint of which to contain a drachm of carbohc acid, every four hours. The following morning there was no improvement in the pulse, temperature, pain, or swollen condition of the uterus, and the lochia, in spite of the douches, were still offensive. It occurred to me that a continuous douche would not only be of great service in rendering the lochia harmless, but would be of immense value in reducing the inflammation. Accordingly I made and, after bringing them to a proper temperature, applied the abdominal and vaginal coils. I both carbolized and mercurialized the douche-fluid in the reservoir by adding two drachms of carbohc acid and one grain of the corrosive chloride to the two gallons of water. The abdomen was kept as hot as she could bear, and the vagina full of the hot fluid. The patient regulated the flow by the stopcock on the reservoir, which was placed by the side of the bed and elevated ten or twelve inches. She immediately expressed herself as receiving great comfort from the continuous douche, and insisted over and over again that it gave her greater relief from the pain than any other measures we used. The flow was continued for forty-eight hours with two or three short interruptions to relieve her from the disagreeable pressure of the bed-pan, which was of the ordinary china variety. The improvement of the symptoms was immediate and continuous from the hour of the application of the apparatus. The inflammation was quickly dissipated and the pulse and temperature became normal at the end of the forty-eight hours.

From this case I am led to believe that a continuous hot vaginal douche will do more satisfactory work in reducing acute inflammation of the pelvic organs and membranes than any other single remedial agent. Six months before the above attack this lady had a dangerous metritis following childbirth. For nearly seventy-two hours two trained nurses applied hot fannels to her abdomen with unceasing regularity, until, at her urgent request, I directed them to be less assiduous in their attentions. She was so annoyed by the constant changing of the fannels in that sickness that the apparatus used in the last one was most thoroughly appreciated and commended. The vaginal coils I have used in two cases after childbirth. The first was kept in position eight days. The second I applied to Mrs. B. yesterday morning, January 20th.<sup>2</sup> In neither case was there any discomfort produced by them. As they saved the nurses much trouble and the patients the disagreeable application of syringe nozzles, the coils became very popular in both families.

<sup>2</sup> February 7th. The coil came away from Mrs. B. to-day while she was walking about the room, having been in position eighteen days. She says that there has been no pain or disturbance whatever from it.

—We have received the prospectus of a new periodical to be called *Mind in Nature*, whose object is to furnish, in a popular manner, information regarding physical questions. It is issued by the Cosmie Publishing Company, of Chicago.

## RECENT PROGRESS IN ANATOMY.

BY THOMAS DWIGHT, M.D.,

*Parkman Professor of Anatomy at Harvard University.*

ONE of the signs of the progress anatomy is making is the attention paid to the significance of both normal and irregular structures with a view to throwing light on the great questions of the day. We refer to the papers on the nature of ligaments and muscles, showing their changes during the development of the individual and the diverse appearances in various animals of muscles that are held to be the same. Much is doing in animal mechanics; and very great attention is given to anomalies, not merely as curiosities nor for the surgical importance they sometimes present, but as indications in one species of the normal appearances in others. A curious question, which opens a field that is almost absolutely new, is the inter-relation of anomalies. If a subject presents a certain muscular anomaly, is he the more likely to present certain others in the vascular and nervous systems, and, if so, what bearing has one on the other? We can easily conceive of cases in which an anomaly in one system necessitates one in another; but there are instances of the simultaneous occurrence of anomalies in which the relation of cause and effect is not easily seen. The following discussion shows instances of both kinds:—

## ANOMALIES OF THE ARCH OF THE AORTA, OF THE RIGHT INFERIOR LARYNGEAL NERVE, AND OF THE THORACIC DUCT.

Dr. Brenner,<sup>1</sup> of Vienna, reports some interesting cases of anomalies of the arch of the aorta, and discusses the effect on the inferior laryngeal nerve of irregular origin of the right subclavian.

Dr. Brenner has observed three cases in which, with an aortic arch pursuing a normal course, the right subclavian is the last branch, and three other cases of anomalies connected with the passage of the arch of the aorta over the right bronchus.

We will remind the general reader, who may not be as familiar with embryology as he has been, that of the five right and left branchial arches which exist (though not all at once) in the fetus, the fourth arch on the right, originally the right root of the aorta, becomes the right subclavian, while that on the left becomes the arch of the aorta, from which the left subclavian is an offshoot. The fifth arches spring from the pulmonary artery. The left one becomes the ductus arteriosus, the right one (in mammals) disappearing very early. The recurrent laryngeal nerves leave the pneumogastrics at the lower border of these fifth arches. As the right arch disappears, and, as the left one joins the aortic arch, it follows that the nerves practically pass under the vessels which represent the fourth arches.

Two of the cases of the first group were similar in all essential respects. The branches from the aorta were in order, the right carotid, left carotid, left subclavian, and, from the descending portion, the right subclavian. In these cases the right, fourth, and fifth branchial arches atrophy early, and the right subclavian is the lowest part of the right aortic

root, which unites with the left one to form the descending aorta. There is nothing to carry the inferior laryngeal down and consequently it runs directly to the larynx.

The third case appears nearly the same, but is very different. The first artery to leave the arch of the aorta was a vessel that divided some two inches from its origin into the right vertebral and the right carotid; then came the left carotid, the left vertebral, the left subclavian, and finally the right subclavian, as before. The vertebrals entered the transverse foramina of the fourth cervical vertebra. The right recurrent nerve in this case left the vagus opposite the sixth cervical vertebra, turned round the vertebral to reascend to the larynx, while the filaments to the lower part of the trachea came directly from the trunk of the vagus. Why this difference? Because the right vertebral artery in this case represented the fourth right branchial arch. A very peculiar feature of these three cases is that in each of them the thoracic duct emptied into the veins on the right side of the neck instead of on the left.

That this connection was not accidental is shown by the following case observed at the Harvard Medical School in the present year and not yet reported. It was noticed during the dissection of the neck that there was no recurrent laryngeal nerve on the right side but that the nerve ran directly to the larynx. Directions were given to search for an anomaly of the right subclavian, and it was found essentially as in Dr. Brenner's two first cases. Directions were also given to look for the thoracic duct on the right side, but unfortunately the veins were removed prematurely. It was found, however, running up on the right side of the right subclavian artery to the very top of the thorax, so that it is hardly possible to doubt that it emptied into the veins on that side.

Brenner's three cases in which the aorta passed over the right bronchus are extremely curious, but we have no space for a thorough analysis. In one of them the course of the nerves and of the thoracic duct does not appear to have been observed. The others give conclusive evidence that the nerves pass under the fifth branchial arches, represented by the ductus arteriosus, for in one case in which the fourth arch was wanting and the duct on the same side present—at least, or a cord—the nerve turned under the latter. No anomaly of the thoracic duct appears to have been observed.

Professor Turner,<sup>2</sup> in his almost classical paper on the irregularities of the large bloodvessels, published a letter from Professor Allen Thomson, in which the latter described a case of the aortic arch passing over the right bronchus in which the thoracic duct ended on the right side. In this case the vessels from the arch occurred in the following order: an innominate dividing into the left carotid and subclavian, then the right carotid, and lastly the right subclavian. The recurrent nerve on the right side turned under the arch of the aorta, on the left under a cord which probably represented a left ductus arteriosus. With regard to the fact that the thoracic duct ended on the right side while it apparently did not in Brenner's cases of a right aortic arch, it

<sup>1</sup> Archiv für Anatomie und Entwickelungs-geschichte, 1883.<sup>2</sup> Brit. and Foreign Med. Chirurg. Review, 1862.

should be mentioned that in this case the order of the great vessels was a different one.

Mr. Arthur Thomson's<sup>3</sup> discussion of the cause of the variations of the thoracic duct is interesting in this connection. Professor Morrison Watson divides the cases of the duct ending on the right into those in which there is also an irregularity of the vessels and into those in which there is not. There may be two ducts, one opening on either side, or there may be a bifurcation of the duct with a similar termination. We see no reason why Professor Watson's subdivision should not apply also to each of these classes. Mr. Thomson reports two cases he has observed in which the right subclavian was the last branch and in which the thoracic duct opened on the right. (In one of these cases, as in the Reporter's, this point could not be absolutely determined.) Cases essentially similar have been reported by Cruikshank, Todd, and Macdonald Brown. Mr. Tompison reports a third case which resembles somewhat Dr. Brenner's third case—the important point however is that here the duct also ended on the right. It passed up behind the subclavian artery, while in this observer's two other cases the duct went before it.

Mr. Thomson remarks that "it would be interesting to know, if, in every case of origin of the right subclavian from the right aortic root or transposition of the aortic arch, a similar disposition of the thoracic duct existed, as it would lead us to presuppose that the transposition of the duct to the right side had some connection with these arterial anomalies." Dr. Brenner's cases of right aortic arch without transposition of the duct show that the association is not necessary, and moreover Professor Watson reported a case<sup>4</sup> of the duct opening on the right side, in which no lesser duct could be found on the left and in which there was no anomaly of the large branches from the arch. This seems at first sight opposed to Mr. Thomson's suggestion that the thoracic duct is formed from lymph-vessels that are developed beside the large arterial branches so that any cause of a diversion of the current from any part of one system would affect the other, and thus there would be a general correspondence between them. The view attributed to Hense that there are communications between the thoracic duct and the right lymphatic duct which may become enlarged and thus turn the current either way appears plausible, though, as Mr. Thomson states, we are not aware that any such anastomosis has been demonstrated. It seems to us very possible to harmonize the two theories, but it is desirable that a greater number of thoracic ducts should be studied to decide this interesting question.

#### MUSCULAR ANOMALIES.

A very useful work on anomalies of the muscular system has recently appeared in France.<sup>5</sup> It is not free from serious defects; but we will not discuss them here. It is valuable for the abundant, almost exhaustive account of the literature of anomalies, and for the sections on comparative anatomy

which tells us in what animals certain arrangements are normal that are irregular in man. A great deal has recently been written about the *musculus sternalis* (*supra-sternalis* or *sternalis brutorum*) and many divergent views defended. It lies near the median line over the sternum and presents many phases. It is frequently attached to the sheath of the rectus, frequently is continuous with the sterno-cleido-mastoid, and occasionally more or less united to the pectoralis major. Nearly twenty years ago Professor Turner<sup>6</sup> expressed the opinion that it was to be considered a rudiment of the *panniculus carnosus*, though he recognized that the *platysma*, which is generally held to have a similar significance, lies more superficially than the *sternalis*.

Bardeleben,<sup>7</sup> in an article involving great research, in which he gives a table of one hundred and twenty cases of the anomaly, maintains, and we fully agree with him, that it may represent different muscles in different cases. He thinks it may be a variation of the *rectus abdominis*, of the *pectoralis major*, of the *sterno-cleido-mastoid*, of the *panniculus carnosus*, or of the two latter at once.

It is evident that the old idea that as a rule it was due to the extension upward of the *rectus* is quite absurd, as it lies above the sheath of that muscle, and in animals in which the *rectus* reaches higher than in man, it runs beneath the pectorals. Still there are cases in which the *rectus* extends beyond its usual limit. These, however, would account for few, if any, of the cases of the anomaly in question. In this connection an observation by Mr. Dobson<sup>8</sup> is of great interest. In the golden mole the *rectus* runs to the first rib superficial to the pectorals. This is an altogether exceptional occurrence, for which Mr. Dobson offers the explanation that it is due to the shape of the thorax. He thinks Professor Turner's difficulty in calling the muscle a rudiment of the *panniculus*, while it is deeper than the *platysma*, may be got over by regarding the *musculus sternalis* as homologous, not with the *panniculus carnosus* lining the integument, but with the *sterno-cutaneous* (*sterno-facialis* of the hedgehog) which is found in many species of mammals springing from the sternum (extending in some even as far down as the sheath of the *rectus*) and attached to the deep surface of the *panniculus carnosus* either in front or behind of the anterior extremities. The very variable condition of the anterior attachment of the muscle in man also agrees well with this hypothesis, for the rudimentary muscle having ceased to have any function, and having lost its connection with the feebly developed representative of the *panniculus carnosus*, attaches itself irregularly anywhere, though the position of its origin remains to a great extent unchanged.

Mr. Abraham exhibited some anencephalous fetuses before the Academy of Medicine in Ireland,<sup>9</sup> which presented fine specimens of the muscle in question which, he argued, is an aberrant portion of the *pectoralis major*. It is a curious fact that he found it in six of eleven anencephalous fetuses.

<sup>4</sup>Journal of Anatomy and Physiology, vol. XI.

<sup>5</sup>Les Anomalies Musculaires chez l'Homme, expliquées par l'anatomie comparée. Leur Importance en Anthropologie. Le Docteur L. Testut, 1881.

Journal of Anatomy and Physiology, vol. I.

Zeitschrift für Anatomie und Entwicklungsgeschichte. Bd. I.

<sup>8</sup>Journal of Anatomy and Physiology, vol. XXII.

Transactions, vol. I., 1883.

The writer of this report finds among his notes an account of a dissection of such a specimen in which the sternal part of the pectoral was divided on both sides, and which presented a sternalis on the right and one on the left, which was interrupted in its course; the lower portion running from the cartilage of the fourth rib to that of the third, and the upper from the third cartilage to the second.

Dr. J. D. Cunningham<sup>10</sup> finds support for Mr. Abraham's view in the fact that he was able to trace a branch of one of the thoracic nerves (which supplied the great pectoral) to a sternal muscle. It is very much to be desired that the nerve-supply should be ascertained in every instance, though, unless the results should present great uniformity, it may be doubted whether great stress should be laid on this point.

We come at last to Dr. Testut's opinion; but before giving it we would mention that he mentions cases in which the muscle has been found in the living, and its nerve-supply sought by electricity. In one case it responded to irritation of the thoracic nerve, and in another to irritation of the intercostal. We cannot conceive by what process of reasoning it is deduced by Mallbranc that in the latter instance the muscle belonged to the sternomastoid. Testut maintains that the upper portion of this muscle belongs to the sternomastoid and the lower to the external oblique, as it often arises from its fascia. He points out that this is not so surprising as appears at first sight, for the sternomastoid and great oblique have much in common: a common direction, an insertion in the same plane, and the same relation to the integument (which last point we do not feel sure about). Now, in serpents the anterior fibres of the great oblique arise from the mastoid process, and constitute a superficial rectus on the ventral aspect of the animal. Humphrey considers these fibres in the serpent homologous with the sternomastoid of batrachians, birds, and mammals. Testut argues that the apparition of a sternum and the anterior limb separates these muscles, originally one. We might reply that if man descended from the serpent there would be rather a long interval between the loss of this muscle and its reappearance as an anomaly; but as no one maintains this theory, but at most that they come from some common ancestor, we may well be startled at the ages during which this muscle has lain dormant. The evolutionary theory, which is too often imposed upon us as an article of scientific faith, is responsible for a great deal of nonsense.

<sup>10</sup> *Journal of Anatomy and Physiology*, vol. XXII.

—At a recent meeting of the Midland Medical Society, of England, Mr. Bennett May showed a girl whose common carotid artery he had ligatured for hæmorrhage from the external auditory meatus, undoubtedly due to erosion of the internal carotid artery occurring during the fourth week of an attack of scarlatina. The girl had thoroughly recovered, and Mr. May remarked that the case appeared to be the only successful one of the kind recorded. Politzer stated that thirteen cases of a similar nature were to be found scattered throughout surgical literature, and that every one of them had terminated fatally.

## Reports of Societies.

### SUFFOLK DISTRICT MEDICAL SOCIETY.

#### SECTION OF OBSTETRICS AND GYNÆCOLOGY.

ROBERT E. DIXON, M.D., SECRETARY.

JANUARY 21, 1885. DR. JAMES R. CHADWICK in the chair.

DR. W. SYMINGTON BROWN, of Stoneham, by invitation of the Society, read a paper entitled

#### FORTY YEARS' EXPERIENCE IN MIDWIFERY.

DR. W. L. RICHARDSON said that he agreed with the reader in very many of the important points that he had brought forward in his paper, although differing from him regarding the use of vaginal injections. He, however, disagreed with Dr. Brown about introducing the left hand only in the operation of version, but should say it would be far preferable to use that hand which, when inserted into the uterus, would be toward that side where the feet of the child lay.

DR. BOARDMAN remarked upon the difference of opinion held by eminent men concerning the choice of the high forceps operation or version. He said that he was taught that version should always be done when the head was above the superior strait. During the first few years of his practice he used high forceps in preference to version, but now he has gone back to his old teachings, and in the generality of cases prefers version. Anaesthetics he considers to be valuable in the second stage of labor. The chief objection made to their use is that they interfere with the action of the uterus, and are liable to cause post-partum hæmorrhage. In private and hospital practice he gives ether to complete anesthetization for obstetric operations, and has never had a case in which post-partum hæmorrhage followed. He is satisfied, too, that, in the first stage of tedious labor, ether, given in small quantities sufficient to afford comfort, will promote regularity and increase the efficiency of the contractions, so as to favor dilatation of the os, which before had been rigid. He has observed this particularly in recent cases at the Lying-in Hospital, where the more usual employment of chloral had failed to accomplish the object desired. Very decided opinions upon either side of this question have frequently been expressed at some of our Society meetings, and as this meeting was unusually large he thought it well to allude to this point for discussion in order to elicit an expression of opinion from the experience of many gentlemen present who have had a large obstetrical practice.

DR. McCORMACK asked the reader his reason for using, in preference to ether, a mixture of ether, chloroform, and alcohol.

DR. BROWN replied, simply because it seemed more applicable.

DR. RAYMOND mentioned that the last meeting was hardly ended when a member made a statement of great interest in regard to the question that had been debated, the outcome of an extended hospital experience. Dr. Richardson, who is present to-night, will perhaps repeat what he then said. Possibly the Society may direct the Secretary to let the words

appear as an addendum to the minutes. It is much to be desired that diligent search be made for the isolated, and, it may be, quite exceptional, instances of pain following a vaginal douche, of which rumors come to us, that the comparative frequency or infrequency of these events and their importance may become matter of accurate record.

Dr. RICHARDSON remarked that he could but think that the unfavorable symptoms in the few cases mentioned at the last meeting must have arisen from some carelessness on the part of the nurse while giving the douche. At the Boston Lying-in Hospital the thousands of douches that have been given without an unfavorable symptom made the question of the danger of the douche peculiarly pertinent.

Dr. REYNOLDS considered that the prohibition of version after escape of the liquor amnii must not be absolute. Under these conditions full anaesthesia is a wonderful resource, and its use greatly enlarges the scope of the operation. Where the presenting head has already come well down, adjusting the blades of the forceps over the fetal ears is undoubtedly better, more accurate, and safer, though serious objection cannot be made to the method which the paper prefers. We are still without a sufficient number of reliable data establishing the precise effect that lying-in repose has in favoring involution. The arguments in support of early getting-up have not, as a rule, commended themselves to the medical profession. The immense majority of women must soon be again on their feet whether they will or no. There are very few to whom at any period of life a few weeks of quiet will not be an unmixed good. Especially is this the fact when to the discomforts attending the close of pregnancy succeed the exhaustion of delivery and the weariness of early nursing, with its ever-interrupted sleep and its nightly drain. We may dream of a creature who laughs at these disabilities, but to the every-day patient they are very grave evils.

Dr. SINCLAIR said that vaginal douches have for years been given in hospital practice and in the practice of younger men. While physician at the Lying-in Hospital he had instructed that vaginal injections should be used regularly. At one time he was undecided regarding their acting as a cause for the spread of the germs of puerperal diseases. In private practice it is his custom not to use the douche unless indicated by some unfavorable symptoms, as rise of temperature and fetid lochia. He fancies that the routine practice of using douches will not survive much longer. Regarding the applicability of ether in midwifery practice, he considers Dr. Brown's plan of administration admirable. His own habit has been, and is, to allow the patient ether if she demands it, or it is indicated by her condition. He considers the early use of ether as bad practice, and prefers to give it toward the end of the case. Ergot, he thinks, is contra-indicated till after the birth of the child, while disinfectants he uses if bad symptoms develop.

Dr. Cobb asked the reader his reasons for using intra-uterine douches at a temperature of 130° F.

Dr. Brown replied that he uses injections at that temperature to arrest post-partum hemorrhage.

Dr. Cobb then asked the reader his experience with chloral.

Dr. BROWN answered that he had had very little experience with chloral, but when he had used it he had been pleased with its effect. He prefers to use it instead of ether in the early part of the second stage of labor.

Dr. GALVIN asked the reader what his percentage of deaths had been following operations.

Dr. BROWN replied that he did not know, but of his three cases of craniotomy two women recovered and one died.

Dr. DOE remarked that in those cases in which the patient suffered extremely during the first stage of labor, it was his practice to administer ether in sufficient amount to quiet the patient during her pains. He almost always uses ether during the second stage of labor. He had had but one case of post-partum hemorrhage after administering ether, and to this patient but a small amount had been given, and that during the first stage. It was omitted on account of the increased nervous excitement it produced. Although the case terminated naturally half an hour later, hemorrhage followed the delivery.

Dr. MARCY considered it a wise plan to administer chloroform during the first stage if pain is severe, and later give ether if it was needed for operative procedure. Chloroform acted more rapidly and could be used to lessen suffering and yet not make the patient insensible.

He had no doubt that post-partum hemorrhage was much more frequent after anaesthetics and he had observed a number of cases which he attributed solely to their use.

Dr. NORMAN said that for years he had used anaesthetics when the patient asked for them, for he considered them necessary. Generally for operations he uses ether, but not always. He never uses ether during the first stage. If the os is hard and undilatable and the pains ineffective, he gives chloral hydr. and brom. pot., which usually acts satisfactorily. He never uses chloroform in obstetric work.

Dr. BENJAMIN CUSHING mentioned that he had used chloroform formerly in preference to ether, liking its effects better, but of late he had not felt at liberty to risk the danger of its use.

Dr. MINOT wished to call attention to compression of the abdominal aorta, as a means of controlling post-partum hemorrhage, which he had more than once employed with apparent benefit. Considering the ease with which this can be done after delivery, he thought it remarkable that so little attention was paid to what would seem to be an obvious expedient in the emergency. It is hardly noticed in the textbooks.

Dr. ERNEST W. CUSHING asked if those physicians who allow their patients to get up quickly are not those who do not use douches, and, *vice versa*, if douches are not rendered more necessary by keeping the patient continually on her back. Chloroform, he thinks, administered in whiffs in the first stage, produces better results than does chloral, is more easily controlled, and, according to the opinion of all the world outside of Boston, not at all dangerous.

Dr. GRANGER spoke of the value of pressure upon the aorta through the uterine wall for post-partum hemorrhage. He mentioned a case of post-

partum hemorrhage where ice, ergot, and the hand in the uterus, had been tried, but the hemorrhage continued. He then applied pressure to the abdominal aorta, through the posterior uterine wall, causing the hemorrhage to cease at once, and his hand acting as an irritant excited the uterus to contract around it. Version after the evacuation of the liquor amnii had been attendant with no bad results in his practice, but he had sometimes had difficulty in inserting his hand into the uterus. He mentioned a case that he had seen in which the liquor amnii had escaped thirty-two hours previously, and an arm was prolapsed, the hand showing externally. Version was performed with difficulty, and the woman was delivered of a live child. He favored version when the head was above the superior strait whether the membranes were intact or not. He considers opium of great value in post-partum hemorrhage given in two thirds of a teaspoonful dose, from its acting to resuscitate the patient by stimulating the heart.

Dr. BROWN, in closing the discussion, said that it is not Listerism but cleanliness that produces beneficial results in the practice of midwifery, and from cleanliness the good results are due. Any one familiar with the filthy state of British and Continental hospitals thirty years ago, and their present improved condition will be likely to admit that one factor in the lessened death-rate is cleanliness; and this improvement dates from the time that Sir Joseph Lister commenced his antiseptic crusade in Glasgow. Another item in midwifery success is the greater frequency with which forceps are applied or version effected. Dr. Robert Collins, in over sixteen thousand cases at the Dublin Lying-in Hospital, only used the forceps eleven times, while during the same period—1826 to 1833—craniotomy was performed seventy-nine times! We have made progress since that time.

Dr. M. A. MORRIS, of Charlestown, read a paper entitled

### THREE CASES OF PELVIC HEMATOCLE. — ONE DEATH.

Dr. MARCY remarked that he had had several exceptional cases of hematocle similar to those mentioned by the reader. Two histories he gave in brief outline. One was a woman who, on the fourth day after being delivered of twins, developed suddenly all the symptoms of collapse. An ovoid tumor appeared, nearly as large as the uterus before delivery. The uterus was crowded down into Douglas's fossa. Later, it was clearly determined to be a subperitoneal hematocle. After many months it diminished in size, and convalescence came on. Another remarkable case was that of a woman who had never been pregnant, who was suddenly seized with severe pelvic pain, followed by collapse. For days her life was despaired of, and weeks later a large amount of broken-down blood was evacuated by the rectum. She is now well. He also mentioned a case of hematocle which was pressing on the uterus. The insertion of an aspirating needle was soon followed by septic symptoms. A large opening was then made, the broken-down contents evacuated, and carefully cleansed with carbolic acid, and the woman recovered. Dr. Marcy raised the question if, in cases of pelvic hemor-

rhage, like one reported by the reader, where the diagnosis was reasonably assured, it was not a justifiable procedure to perform laparotomy and search for and secure the bleeding vessel.

Dr. SINCLAIR said that, having made a differential diagnosis, the question then arose as to the best method of treatment. Some cases of hematocle he had opened, others he had let alone. If a hematocle is opened there is then risk of septic trouble, and great care is necessary in keeping the parts clean. He believes, on the whole, in the non-operative treatment.

Dr. CHADWICK recalled two cases in which he had great difficulty in making a diagnosis. One was that of a woman who, for six weeks before he had seen her, had considerable pain in the lower part of the abdomen. Upon examination, a tumor was found between the vagina and the rectum. Fluid could be felt, apparently pus, pointing toward the rectum, and blood followed the insertion of a trocar through the posterior vaginal wall. Great difficulty was then experienced, for two or three days, in checking the flow of blood, which came into the cavity of the hematocle as fast as it ran out below. It was finally checked by plugging the vagina. This, then, is one danger of operating, and another is that of septic poisoning. He has never seen a physician who has had a case of encysted hematocle or pelvic abscess that had ruptured into the peritoneal cavity.

Dr. GALVIN asked why, if one was sure of his diagnosis, he could not press on the aorta with good results when severe hemorrhage followed the opening of a hematocle.

Dr. CHADWICK replied that in his case it would have been necessary to have compressed the aorta for several days, a much longer period than was feasible.

Dr. DOE mentioned a case that he had had in his hospital practice, in which the question of abscess or hematocle arose. He inserted a fine aspirating needle, and drew off a small amount of blood. Septicæmia followed, and three weeks later the contents of the sac had become purulent. A drainage-tube was inserted, and recovery ensued.

Dr. CHADWICK remarked that septicæmia generally follows puncture of the sac in extra-uterine pregnancy. In two of Dr. Morris's cases he thought there was a possibility of extra-uterine pregnancy being present.

Dr. MORRIS said that in his cases the symptoms of pregnancy were absent. One of the cases he at first thought was a miscarriage, but later he decided that it was not.

Dr. GEORGE W. GALVIN reported a case of

### ANENCEPHALIC FETUS,

and exhibited the specimen.

Mrs. T., aged twenty-six years, became pregnant about seven months ago, and succeeded in having an abortion performed. At the time I first saw her she had been delivered of an anencephalic fetus, but the afterbirth had been retained in utero. The woman at this time was in a state of collapse, but after the removal of the placenta and the administration of stimulants, she rallied and was soon out of danger. She stated that the fetal move-

ments ceased about one month before the birth of the fœtus, but there was nothing about the appearance of the child to indicate that it died in utero, and, as there was bleeding of the cord after division, there is a strong probability that life was not extinct at birth. The number of names given to monstrosities lacking cranial development is something enormous. It is evident from the external appearance of this particular specimen that the cervical vertebrae fall short in number, but there is an atlas and axis. The base of the skull is undoubtedly occupied by a partially developed cerebellum. The cerebrum is wholly absent. The age of the fœtus is probably between seven and eight months.

DR. DAVENPORT explained the uses and advantages of the douche pan and pail of Dr. W. H. Baker.

DR. CHADWICK exhibited a douche-pan devised by the late Dr. T. B. Curtis, which consisted of a large, flat, round pan of tin, the edges of which turned up and back toward its centre, so as to support a common annular inflated rubber cushion. The tin pan had an overflow-pipe. This contrivance raised the hips as much as does that of Dr. Baker, without necessitating the building up of the bed with pillows, etc., which his patients had complained of as very difficult and laborious.

DR. FORSTER showed a new form of douche-pan, of his invention, which is now on trial at the City Hospital.

DR. R. B. DIXON explained the advantages of a douche-pan invented by Dr. W. M. Searby, of San Francisco, the rights to which are owned by Mr. F. W. Dudley, of Lakin's Pharmacy. The pan is of large size, and its shape is such that it can be easily placed in position for use, and the patient can remain undisturbed in a recumbent position as long as may be necessary to inject a large volume of water, no discomfort from wet or any other cause being experienced. The pan is used largely in hospital practice and is highly spoken of. One great advantage it possesses over the other pans exhibited is that it is by far the least expensive of them all.

DR. C. P. PUTNAM showed on the blackboard that a large sheet of thin rubber could be doubled up and fastened in lines with rubber cement in such a way as to secure a to-and-fro current of hot and cold water, thereby accomplishing the same result as from more expensive apparatuses.

## THE NEW YORK STATE MEDICAL ASSOCIATION. FIFTH DISTRICT BRANCH.

### SCIENTIFIC MEETING.

HELD at the Clarendon Hotel, Brooklyn, on Wednesday, February 25, 1885.

The President, DR. JOSEPH C. HEDDINSON, of Brooklyn, called the meeting to order and delivered an

### ADDRESS OF WELCOME.

The desire of the friends of medicine, represented by the Fifth District Branch, he said, was ultimately to arrange for frequent meetings in King's and other

counties of the district. It was entirely easy for physicians to enter the fellowship of the Association. All who became members of the State Association were, by virtue of that relation, members of the Branch Association of this district, and there were more than five hundred members who joined the former during the first year of its existence. Still, mere members are not the object; the aim was to get the best material for effective and congenial work on behalf of the best interests of the profession and of the public. One of the great features was freedom from legal control or complications. The Association wanted nothing to do with the Legislature or any other political body. It desired to be free to admit or reject whom it pleased. At all times ready to give information, when requested, to the civil authorities, executive, legislative, or judicial, it still wished no official connection with them; for medicine was a voluntary, self-independent profession, governed by its own rules.

At the same time, toward all brethren of a like faith, but of a different policy, all present, he knew, would have only the kindest feeling. Men of culture and honor could differ without anger or loss of mutual self-respect. He felt persuaded that as this Branch Association completed the initial work of organization and dealt with the objects germane to the profession, their union would be found pleasant and profitable, and one crowned with the approbation of their consciences, and with beneficial results to humanity, to science, and to themselves.

DR. J. W. S. GOULEY, of New York, read a paper entitled

### NOTES ON CONTRACTURE OF THE BLADDER, CONSEQUENT ON CYSTITIS.

The existence of this condition of contracture, which might be general or limited in extent, was often not discovered until the difficulty had become irremediable; but if taken in hand early it was usually quite amenable to treatment. Having mentioned a large number of exciting causes which might give rise to cystitis and contracture, he proceeded to speak of some of them in detail. Hysterical women and men of nervous temperament are particularly liable to such trouble, and polyuria, which was frequently met with in this class of subjects, was a very common cause of cystitis. The quantity of urine passed would soon become diminished with each act of urination, while the desire to urinate would constantly increase, until violent contractions of the bladder would result, and permanent contracture be threatened. On the other hand, a condition of the urine in which the specific gravity was very high, as in diabetes mellitus, instead of being low, was also liable to give rise to cystitis and contracture of the bladder. The explanation of the same effect being produced by urine of opposite character was that when the specific gravity was low the epithelial cells of the vesical mucous membrane by an endosmotic process became swollen, died, and were cast away, while, when the specific gravity was high, the epithelial cells, by an exosmotic process, shriveled, and then died, and were cast away. In either case the divided mucous membrane suffered constant irritation from the urine in contact with it.

In speaking of uterine displacements as a cause of contracture, he referred to a very severe case of the kind which he saw some years ago in consultation with the late Dr. George T. Elliott, where the anteverted uterus was held firmly in its malposition by adhesions and could not be replaced. Acute urethritis in the male sometimes resulted in permanent contracture with sclerosis of the connective tissue of the bladder; and the same was true of chronic urethritis, as well as of neglected stricture. Having described the *modus operandi* by which prostatic obstruction gave rise to a similar condition, he remarked that hypertrophy of the bladder was the almost universal rule in enlarged prostate, and that he had yet to see the first instance of atrophy and atony, which was claimed by some authorities as the usual result. Certain diseases and injuries of the nervous centres were among the causes of contracture; and if the bladder was paralyzed incontinence, and not retention, of urine would be the consequence.

He then called attention to the use of ether given as an anæsthetic as an exciting cause; referring to it, he said, as a special warning to surgeons. The action of this agent was twofold: first on the kidneys, producing polyuria, and second on the urine, which it rendered irritable in character. To avoid the unpleasant results that were liable to follow, he advised that patients about to undergo an operation should be required to urinate immediately before taking the ether and immediately after recovering from its influence.

In speaking of the treatment, he referred first to the remedies having an effect upon the general system, which are of two kinds: first, those tending to diminish pain by their influence on the nervous system, and second, those affecting favorably the character of the urine. Opium in a few full doses was often of great service at first; but, except when there was polyuria, it had an injurious effect if kept up for any length of time; while in polyuria it was undesirable to maintain its use on account of the danger of the patients getting the habit of taking it. Belladonna was very useful, but unfortunately it could not be administered for more than two or three days in succession, on account of its toxic effects; and the same was true of hyoscyamus and its alkaloid hyoscyamin, which Dr. Squibb had advised should always be given hypodermically on account of its liability to become decomposed from the acid condition of the stomach. He also spoke favorably of the use of gallic acid, ergot, and citrate of soda, as well of the tincture of the chloride of iron and of salicin combined with bromides. No good result could be obtained from any agent, he claimed, unless the rectum were kept empty.

He spoke next of the local treatment. The application of leeches to the hypogastrium or perineum, or both, was only permissible in young and robust patients. For the relief of cystitis and contracture at the same time, one of the best measures was the slow and gradual hydraulic dilatation of the bladder. Sudden dilatation under an æsthetic was apt to be followed by bad consequences. In any given case the surgeon would be able to tell after a few days about how much good was to be expected from the use of gradual dilatation. For instance, if at the

first sitting the capacity of the bladder was found to be only one ounce, and at the next that this had been increased half an ounce, and if at the third sitting it was still another half-ounce greater, there would be a good prospect of speedy relief and perhaps cure. If the urine remained purulent, it was recommended that nitrate of silver should be employed, beginning with a solution of the strength of only one tenth of a grain to the ounce. It was seldom necessary to use a solution of greater strength than one grain to the ounce. After a stone or foreign body which had given rise to cystitis had been removed, it was of the utmost importance that the condition of the bladder should be carefully attended to: a point which was often neglected by surgeons. After lithotomy and lithotrity it was not uncommon to see vesical contracture resulting, which with proper care might have been avoided.

Dr. E. R. SQUIBB, of Brooklyn, alluded to the change which had been made of late in the preparation of official tincture of the chloride of iron, which, by depriving it of the nitric acid which was formerly present, prevented the formation of muriatic ether, which he believed had been of great service in the treatment of urinary diseases. He spoke of hyoscyamin as being a very delicate alkaloid, which was liable to be split up and destroyed as soon as it reached the stomach. Hence he advised that it should usually be employed hypodermically, as was now the almost universal practice in insane asylums.

Dr. ISAAC E. TAYLOR, of New York, spoke of one source of cystitis and contracture which had not been alluded to, namely, ulceration of the urethra. This was generally so small in extent that it was more like a fissure, and hence it was very liable to escape observation. Vaginitis and fissure of the anus, he believed, had often been treated for it.

Dr. ROBERT NEWMAN, of New York, spoke particularly of the good effects of cannabis indica internally and of belladonna and warm water locally, the belladonna being used in the form of vaginal suppositories in females and rectal suppositories in males.

Dr. VAN WYCK said that last summer he had had in his practice three cases of cystitis which were clearly of malarial origin, and which were treated successfully with quinine and other remedies appropriate to malarial trouble.

Dr. RICHMOND spoke of the effects of polyuria in producing cystitis, particularly in young children.

Dr. GORLEY closed the discussion. Referring to ulceration of the urethra, he stated that in a paper on cystitis, which he read in Brooklyn ten years ago, he had mentioned certain lesions of the female genito-urinary, of which this was one, to which attention had never been previously called. As to ulceration of the bladder itself, he said he would defy any one to show him a case of it. He believed that it might perhaps occur once in a vast number of cases, but he had looked in vain for years for an instance of it among the autopsies that he had seen. Practically, true ulceration did not exist, and the only case in which there was anything like an approach to it which he had ever seen was one in which there was a mass of granulations around a

button that had got into the bladder. He was glad that Dr. Van Wyck had referred to malaria in connection with cystitis. The explanation of their relationship was easy, for in the trouble which we called malarial fever there was invariably found lithuria to a most pronounced extent. The uric acid in the urine irritated the bladder mechanically, and sometimes it was in such excess that uric-acid calculi were formed in the kidney itself.

Dr. Austin Flint narrated a

CASE OF ANEURISM OF THE ARCH OF THE AORTA,  
PRESENTING USUAL DIFFICULTIES IN DIAGNOSIS.

and presented the specimen showing the seat and extent of the aneurism. The patient was a gentleman forty-three years of age, whom he had seen in consultation with Drs. Speir and Little, of Brooklyn. He had some difficulty of respiration, but this was not very great at that time. There was, however, distinct stridor; though a careful examination with the laryngoscope, made by the late Dr. Elsberg, had failed to detect any abnormal condition within the range of that instrument. On examining the chest it was found that the respiratory murmur was notably feeble on both sides, being a little weaker on the left side than on the right. Nothing else was discovered to show that there was any affection of the lungs. A careful examination was made for the presence of an aneurismal tumor, but without success, and there was no pulsation disconnected with the apex-beat of the heart. There was no abnormal sound about the heart and there was no aphonia.

The stridor and feeble respiratory murmur, without other cause to explain them, pointed toward the existence of an aneurism, and this diagnosis was rendered the more probable from the fact that, during certain paroxysms of dyspnoea to which the patient was subject, the radial pulse and the pulsation of the carotid artery on the left side were found to entirely disappear. While Dr. Flint and the other physicians were still in consultation over the case they were summoned to the next room to see the patient, who was then suffering from one of these paroxysms so that it seemed as if he must inevitably expire. As a matter of fact he did die in a similar paroxysm within the next thirty-six hours. During the paroxysms the respiration was exceedingly embarrassed; the obstruction to inspiration being more marked than that to expiration. From the nature of these paroxysms it seemed altogether probable that the trouble present involved the transverse portion of the arch of the aorta with the recurrent laryngeal nerve. Coming to consider the morbid appearances in connection with the symptoms which had been noticed during life, it was found that the whole of the ascending, transverse, and descending portions of the arch were markedly enlarged; while there was atheroma present, with distinct calcareous flakes. Yet, what was quite remarkable, there had never been any bruit heard by any physician who had ever made an examination of the case, although it would have seemed that there were just the conditions present for the production of a loud bellows murmur. For the absence of the radial and carotid pulse during the paroxysms, the unusual distension of the aorta and the consequent

pressure on the left subclavian and carotid arteries were sufficient to account.

After having described a pocket half an inch in diameter, which protruded directly into the trachea, and must, of course, have caused more or less obstruction to respiration, Dr. Flint said that an interesting point in connection with the case was the probable causation of the paroxysms of intense dyspnoea, during one of which the patient died. There was no question, he thought, that they were due to the effect of pressure on the recurrent laryngeal nerve; but it might perhaps be difficult to decide whether the urgent dyspnoea was the result of paralysis of this nerve or of spasm of the glottis. With our present light on such matters, he did not hesitate to say that he believed the condition to be one of paralysis, rather than spasm. A question of interest in connection with paralysis of the abductor muscles of the glottis was, Is such a paralysis on one side sufficient to cause death? It seemed probable to him that such was not the case; but where one side was affected, there was a strong liability, through some sort of sympathetic or reflex action, the nature of which was not clearly understood, of the paralysis becoming bilateral. The case was discussed by Drs. A. Flint, Jr., Leah, Little, and others.

Dr. E. R. Squier, of Brooklyn, read a paper on

OLEATE OF COCAINE.

The results of the application of the aqueous solution of cocaine to the skin for the purpose of producing local anaesthesia had, he said, proved very unfavorable. The chief difficulty in its successful application had appeared to be the difference between the epidermis and the epithelium of mucous membrane, and the impermeability of the former. Now there was no possibility of finding a liquid which would pass the epidermis with the same rapidity that the watery solution passed the epithelium; but it had occurred to him that if a preparation could be made which would pass one seventh as fast, and if it were made seven times as strong, the conditions would seem to be met for making as successful applications of cocaine to the skin as to the mucous membrane, as at present practised.

He next gave a *résumé* of the history of the preparations known as oleates and their various applications since they were first mentioned in a lecture by John Marshall, F.R.S., in a lecture in 1872; after which he said that ever since the discovery of the powerful anæsthetic action of cocaine on mucous membrane he had desired to make an oleate of the drug, but on account of its scarcity he had not been able to make any experiments with this in view until the first of February, 1885. He then gave an account of the various steps by which he had arrived at what he believed to be the best preparation for use, namely: one containing twenty-five per cent. of cocaine in an excess of oleic acid; which was just about seven times the strength of the ordinary four per cent. aqueous solution sold in the shops. It was a very expensive article, costing six dollars a fluid-drachm, but there was no necessity for using more than a drop or two of it at a time. Next, having narrated a considerable number of experiments which he had performed for the purpose of

testing the anæsthetic power of the oleate when applied to the skin, he stated that the conclusion thus reached was that the hope which had been entertained that cocaine employed in this way might prove a useful anæsthetic for the skin had been completely disappointed. Except for certain special applications, as for instance, to the glans penis, anus, etc., and possibly for the relief of trigeminal neuralgia, in which it had not yet been tried, the oleate of cocaine had to be pronounced a useless preparation.

When the association adjourned, a collation was partaken of in an adjoining room.

### Recent Literature.

*Insanity and Allied Neuroses.* By GEORGE H. SAVAGE, M.D., M.R.C.P., Physician and Superintendent of Bethlem Royal Hospital, etc. Philadelphia: Henry C. Lea's Son & Co. 1884. Pp. 544.

The works on insanity which have appeared recently, although numerous and, as regards several of them, of great merit in special directions, have, nevertheless, left a gap for further information and practical assistance to students and general practitioners. We were encouraged to find this want met in some degree in Dr. Savage's book from our knowledge of his scientific attainments and his opportunities for the observation and treatment of the insane, but while it contains much to attract the alienist, it is far from complete as a guide to students and younger members of the profession for whom it is avowedly written.

While this is true, the work has nevertheless certain merits for purposes of instruction which should in justice be stated. The author gives, for example, an ideal and practical or working classification, in both of which he has wisely refrained from introducing new groups, and also from overburdening any further the nomenclature of this department with new terms—a most judicious step considering the present state of our knowledge of the subject, and one which can but be helpful to both student and instructor.

But it strikes us as a defect in this manual that the directions for the care and treatment of cases of insanity (except their mere disposal) should be so meagre. We can only explain this on the ground that many physicians will only ask to be enabled to recognize the various forms of mental disease in order to intelligently commit suitable cases as soon as possible to the asylum, or to the care of the specialist in private practice in those cases which the author thinks may be best treated at home; namely, such as are due to fevers or follow childbirth. The unusual prominence given to the prodromal features of the different varieties seem to bear out this view. Nevertheless, even provided we are right in our assumption, we are confident that Dr. Savage's advice concerning the management of cases of insanity in their own homes would be exceedingly useful to many general physicians. Moreover, it would seem that under any circumstances, statements as to the value of hypnotics and other drugs in mental disorders, under various con-

ditions both general and special, would hardly have been out of place, and that some allusion might properly have been made to the requirements for and methods of forced alimentation. The probable duration of presumably curative cases of insanity ought also to have been emphasized. We are told nothing about the detection of feigned insanity, and the author's directions for the examination of insane patients, which are always of practical interest to the certifying physician, are of the most limited kind. The book is further impaired, for purposes of reference, by a most imperfect index.

On the other hand, to those of the profession whose work lies exclusively among the insane and whose experience can readily supply such omissions, these defects will pass for minor ones, while the writer's comprehensive views on insanity in its varied aspects will be welcomed by all. The relation of mental disturbance to physical and, if the distinction may properly be made, to nervous disease, particularly the close connection existing between hysteria and mania and hypochondriasis and melancholia, we have never seen so adequately and clearly presented.

The chapter on emersion is a particularly satisfactory one, the author's treatment of the innumerable popular beliefs and scientific theories on the subject being, for vigorous and judicious statement, exceptionally interesting. He is unsparing in relegating the numerous so-called agencies to their proper places as results of the mental disorder. His descriptions and views of melancholia, moral insanity, puerperal insanity, general paralysis, and paralytic insanity are full of new thought and matter for reflection. His belief in the occurrence of general paralysis without mental disorder is strong, and must be accepted as well grounded in view of his exceptional opportunities for observing the disease in the wards of a general hospital, as well as in the asylum. He has also appropriately given the designation of *acute* general paralysis to rapidly fatal, uncomplicated cases of that disorder, termed by Spitzka "galloping paralytic dementia."

On the whole, while this work may possibly fail to meet the requirements of a textbook, it is so rich in advanced views and sensible suggestions as to make profitable reading to alienists, both in asylums and private practice.

*Helps to Health: The Habitation, the Nursery, the Schoolroom, and the Person.* By HENRY C. BERDETT. Nineteen illustrations. London. Kegan Paul, French & Co. 1885.

The aim of the author has been to present "with sufficient amplitude, but in the fewest possible words, precise information concerning matters which affect the health and comfort of every class from childhood to old age. . . . To be useful, interesting, and reliable is the mission which this volume is intended to fulfil."

The style is concise, clear, and free from technicalities. The chapters on the Nursery, and also on the choice, structure, interior arrangements, the warming, lighting, and ventilation of the house, are especially good.

# Medical and Surgical Journal.

THURSDAY, MARCH 12, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by CUPPLES, UPHAM & CO., Boston. Price, 15 cents a number; \$5.00 a year, including postage.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUPPLES, UPHAM AND COMPANY,

283 WASHINGTON STREET, BOSTON, MASS.

## ANNUAL REPORT OF THE PRESIDENT AND TREASURER OF HARVARD UNIVERSITY, 1883-1884. THE MEDICAL SCHOOL.

The annual report of the President and Treasurer of Harvard University is a document which is always awaited with interest and read with care. This is especially true since the standard was raised and the courses lengthened in the special professional schools; since the post-graduate teaching has been enlarged in scope; since the adoption of elective studies and the substitution, in a large degree, of examinations for recitations in the undergraduate department; since, in a word, the College began to give place to the University.

All these changes have excited, and will continue to excite, discussion. Some of them are definitely accepted; some may be still regarded as on trial; others, of quite as radical a nature,—such as the abolition of Greek as a requisite—are just proposed. Whether all these changes are progressive in the best sense, whether all are judicious, whether some may not be premature, are questions in regard to which there may easily be differences of opinion, questions which are very properly debatable. But, at least, the corollary follows that the University is not dead, is not living in the past, moss and ivy are not its glories. On the contrary, there is life, energy, and activity everywhere, and Harvard has her face set as never before toward the future. This it is which makes these reports of what has been done in each year that is past, and statements of what is aimed at and required for the coming year, of unusual consequence and interest to all concerned with educational questions throughout the country.

Our own concern is more strictly with the Medical School, and the year covered by this report has been for it an eventful one, inasmuch as in the occupation of its new building the school may be said to have fairly entered upon a new career. "This," in the language of the Dean, "has given to the Faculty the opportunity so long desired of arranging its course of instruction in the full possession of all those facilities for work which modern

educational methods imperatively demand. The graded course of systematic instruction adopted may now be carried out to the best advantage."

The new building has given very great satisfaction as regards arrangement of the laboratories and lecture-rooms, but a year's occupation has, as was to be expected, led to certain slight changes in details of construction, and, at the same time, has shown the necessity for more important changes in the method of heating and ventilation which did not answer expectations.

The amount and character of the regular instruction given to students during the year is, as usual, fully set forth in tables which unfortunately are not "appended," but are awkwardly thrust in between pages of reading-matter. A good deal of laboratory work has been done in connection with the anatomical, the physiological, pathological, and chemical departments, and the Warren Anatomical Museum which is not thus tabulated, and the hope and expectations are that the amount of this kind of work will increase every year. Much time has been occupied in the physiological department in the arrangement of the new laboratory and in providing facilities for future work. The investigations previously begun on the action of the vaso-motor nerves have been continued and a preliminary report has been published. A similar study on the action of these nerves in cold-blooded animals has been made under the auspices of the laboratory by Dr. F. W. Ellis, the results of which will soon be published.

In the chemical laboratory the work for the State Board of Health in analyzing the food and part of the milk supply of the State has been carried on.

In addition to the regular instruction in general chemistry, qualitative analysis, and medical chemistry (including urinary chemistry), with special reference to the diagnosis of urinary and renal diseases, and toxicology, special investigations have been made during the year upon the following subjects:—

(1) The distribution of arsenic in the body in cases of poisoning by that substance. This investigation is still in progress, the material being chiefly obtained from cases of suicide by arsenic or Paris green occurring in Boston.

(2) The sources of domestic arsenical poisoning.

(3) The milk and food supply of the State, the material being obtained from the State Board of Health, Lunacy, and Charity.

(4) The water-supply of Boston, specimens from the various sources of supply being obtained from the Boston Water Board.

(5) The sanitary condition of the public schools of Lynn with reference to the contamination of the air in the schoolrooms. This investigation was made at the request of a special committee appointed to inquire into the subject, and the

results appear in their printed report presented to the School Board of Lynn, December, 1883.

Dr. H. C. Ernst has been pursuing special investigations in the physiological laboratory on general bacteriology, and Dr. W. W. Gannett has given special instruction in the methods of examining sputa for the bacillus tuberculosis. Over thirty persons have availed themselves of the facilities offered by the laboratory for histology and embryology, and a large amount of material for future work in these branches has been collected. Dr. C. S. Minot has made considerable progress with a treatise on human embryology which he has under way, specimens illustrative of which are earnestly and continuously solicited from practising physicians.

The Anatomical Museum has profited greatly by the removal to the new building. With proper provision against fire, the whole collection has been brought under one roof, and Dr. J. Collins Warren has added the anatomical collection of his father, the late Dr. J. Mason Warren. The professor of anatomy and his assistants have added, among other things, some very beautiful corroded wax injections of the bloodvessels of various organs, and fusible metal injections of various organs and cavities of the body.

The whole number of students in attendance during the year was 259; during the first term, 248; during the second term, 215. Of these 134 had literary or scientific degrees. There were 64 applicants for the degree of Doctor of Medicine in the three years' course, of whom 14 were rejected. There were 11 applicants for the degree of Doctor of Medicine in the four years' course, of whom two were rejected. Of the nine students who received the degree, two received it *cum laude* and with it the degree of A.M. The Fourth Class was composed of 12 students, five of whom postponed graduation in order to become candidates for hospital appointments.

The following table shows for the last ten years the number of terms spent at the school by graduates.

	1875	1876	1877	1878	1879	1880	1881	1882	1883	1884
Spent six terms	11 47	25 69	40 65	11 85	62 88	39 86	49 81	79 91	67 88	57 96
Spent five terms	7 23	5 1	9 15	2 8	1 2	1 2	6 10	2 2	5 5	0
Spent four terms	6 20	11 18	11 11	3 6	3 14	4 8	1 6	1 1	1 5	2 34
Spent three terms	0	2 5	1 1	0	2 2	0	1 1	0	1 1	0
Spent two terms	3 10	0	3 5	0	1 14	1 2	0	1 1	0	0
Total graduated	30	36	61	18	70	45	60	86	76	59

\* Includes nine students of the Fourth Class.

† Includes six students of the Fourth Class.

‡ Includes nine students of the Fourth Class.

There are two fundamental, though by no means insuperable, difficulties with which the Harvard Medical School has to contend in adhering to its higher standard and lengthened course. A high standard means small classes and consequently high fees in the absence of considerable endowments for the professorial chairs. A rejection of seventeen per cent. of the applicants for a degree means that the examinations are not a farce; it increases the value of the degree for these who succeed, but it deters many others from entering the school. Under these circumstances the only way to lessen the fees is to secure an endowment, and we believe rich men, having the welfare of their fellow-men at heart, could not spend or leave money in a better way.

A four years' course means that a young man who takes a B.A. or a B.S. degree is not ready to begin to try to earn something by his work, instead of spending for training, before he is about twenty-seven years of age. The same difficulty, we believe, makes itself felt in the Law School. There is no doubt that the tendency in this country is wisely toward a more gradual maturing of the young and especially of young men. At the same time a larger proportion of the people are in a position to give their sons a longer time for preparation for their lifework. But the number of young men who find themselves in a position to take four years of college life, beginning at eighteen, and then four or five years of special training is, we believe, still too small to give support to a system. If the time spent upon a sound education is to be less than eight or nine years from the date of entering college, the academical, rather than the strictly professional, period should be abbreviated in most cases, and facilities are already provided at Harvard by which earnest, industrious men can obtain the B.A. degree in three instead of four years.

Fifty-seven persons are now connected with the Medical School. President Eliot tells us, as teachers and assistants, of whom only five were connected with it fifteen years ago. Of the professorships only three have any endowment, and these are very inadequately endowed. There is no professorship of the important subject of public health. About \$6,000 a year is now paid to demonstrators, laboratory instructors, and assistants, in order that the laboratory work of the students may be properly supervised. The annual expenses of the various collections and laboratories, including servants' wages, amount to nearly \$8,000 a year, without counting the cost of heat and light. The school would have had a small surplus at the end of the fiscal year had it not been necessary to take about \$18,000 from its savings to pay the excess of the building, furniture, etc., over and above the amount so generously subscribed at various times for that purpose.

## THE SURGERY OF DYNAMITE.

THE injuries from dynamite explosions have not been very numerous as yet, though if promises hold good we may expect an abundance in the future. Those already wounded show that certain general characteristics may be looked for in the unfortunate victims of such disasters. The only account we have seen of the injured policemen is exceedingly meagre, but it says that the fracture of the ribs which Cole sustained has not been followed by any complication, "but the terrible shock has caused an amount of nervous exhaustion from which he will probably recover but slowly."

Among the persons most injured at the explosion at the Tower of London on January 24th were two young women, aged respectively nineteen and twenty. They were walking arm in arm, and had just entered the Armory when the explosion occurred, the site of the explosion being to their right. They saw a slight flame and heard a report, but the noise did not seem very great. They were thrown down and partially buried by the falling material, and some slight lacerations were inflicted, but they did not become unconscious. The injuries were very nearly the same in both. The younger patient was assisted to her feet after the accident, and had to be helped from the Armory. She felt faint and weak, and unable to walk, but retained her consciousness. She vomited twice during the time she remained at the Tower, and twice after admission into the wards of London Hospital. She complained of no pain. She was somewhat deaf in both ears. In the right meatus there was much dust and *débris*, but she heard no better when this had been removed. She did not recover her hearing for four days. The membranes were not visibly injured; the membrane was ruptured in the elder. They both had dimness of vision, which led them to think the gas turned down when the ward was brightly lighted. Dust had entered the right, but not the left, eye. The younger slept badly, and for the first three nights was so restless as to require morphia. Her temperature in the morning was normal, but it rose a degree each night for the first three nights. Neither she nor her fellow-patient ever complained of headache.

Her chief complaint was of a severe pain along the right inferior dental and auriculo-temporal nerves. She said that this pain kept her awake; it persisted for more than a week, and then gradually subsided. She had never had a like pain before. There was no bruising about the painful regions. The pain was probably referred to these parts from the fibres of the third division of the fifth nerve that had been damaged in the meatus. That the meatus had suffered to some extent was rendered apparent by a somewhat profuse catarrh that set in within a few days of her admission.

It was thought that the vomiting in this case was

due to some disturbance of the branch of the vagus (Arnold's nerve) that reaches the meatus. The patient had well recovered by the time of her discharge.

Mr. Frederick Treves, under whose care these two cases were, makes some very interesting remarks upon them. The general injuries are not to be separated from the injuries produced by similar means. According to Mr. Treves, the point of greatest interest concerns the general effect of the injury upon the nervous system. It is evident that the body must be concussioned or shaken by the explosion, but it would be expected that the effect produced upon the nerve centres could not be identical with the so-called concussion that may follow a blow upon the head or the shock of a railway-collision. The concussion resulting from such accidents as the two last named is produced by a comparatively well-localized and gross form of violence, while the shock from a dynamite explosion would act rather as a force that was diffused and finely divided. In the latter instance, it must be assumed that the individual is not so hurled to the ground as to become the subject of such an injury as may cause concussion in the ordinary clinical sense. The two women whose cases are herewith detailed were not thrown violently to the ground; one of them, indeed, observed that "she was not knocked down, but pushed back." They were both burnt, and both the subjects of some lacerations, but all the injuries were of the slightest character. What symptoms they presented may be ascribed solely to the general shock caused by the explosive, with, perhaps, some superadded emotional influence. It will be seen that neither of them suffered from the clinical condition known as concussion. They were not stunned. Their chief symptoms seemed to have been the outcome of a general enfeebling of nerve-function, whereby the action of the heart was depressed, the vision dimmed, and the hearing—apart from local changes—dulled. It is interesting to note that, in one case, the accident was followed by repeated vomiting. So far as local effects are concerned, it will be seen that the part that suffered most definitely was the *membrana tympani*.

## A QUESTION OF TORTURE.

SOME one, whose protoplasm appears to be in a very explosive state, has been unduly excited by the matter-of-fact report of the Massachusetts Board of Health, Lunacy, and Charity upon the poisonous qualities of water-gas, to which reference was made in our last issue, and has entered his "protest" in one of the daily papers. Remonstrance is not directed, however, as it might well be, against the threatened repeal of the very wholesome law controlling at present the amount of

carbonic oxide in illuminating gas. On the contrary, the writer ignores this source of genuine solicitude, and branches the novel idea that the whole investigation was a "scientific horror"; that the several experiments were "barbarities," and that the rooms in which the experiments were made—built, we believe, expressly to imitate human abodes, and thus to throw light on the insidious dangers of gas to human life—were blood-curdling "torture-chambers."

It is a severe strain upon one's patience to read such nonsense as this in his morning paper. And it is disheartening to feel that no achievement, however worthy in aim, conscientious in execution, or successful in results, tending to promote the general welfare, is safe from mud-spattering by some madly-riden hobbyhorse or other. The investigation in question is a particularly unhappy one for attack on the score of "cruelty"; for not only was the sole object humane and so understood on all sides from the start (having been ordered by the Legislature and directed by the Board of Health), but also, as it happens, of such a nature that, as every physician knows, the question of pain was mostly excluded. It is one of the great dangers of illuminating gas that it offers so easy a death and is so easy to inhale that suicides must often avail themselves of it.

A library janitor, a few days since, in Middletown, Connecticut, whilst attempting to stop a leak in a water-gas pipe, nearly lost his life. He became insensible, and was resuscitated by friends who arrived opportunely on the scene. This is merely the latest of a series of similar mishaps, but it is at once illustrative of the painless character of the lethal process and the insidious dangers of the water-gas.

Again, it has been expressly recommended of late<sup>1</sup> as a painless agent for destroying the lower animals. In short, any one who has looked into the matter knows that death by illuminating gas is not even ordinarily painful. On the mere question of fact, therefore, it ill becomes any one to describe these or any similar experiments as "tortures," "barbarities," "agonies," etc. True barbarism is to be found in this case only in that state of mind and that point of view which give mere sentiment full play and allow it to torture most unmercifully the truth, humanity, and sound common-sense.

On the other hand, is it of more concern to a true philanthropy that a few animals should perish, or that a deadly agent should be introduced into the homes of human beings, and a wise legal provision be repealed without due warning given?

We trust that those who can keep a level head and who have influence will do all in their power to educate and inform the public in these

matters, in order that ignorant sentimentalists may not work mischief, and eventually make the possibility of scientific experiments in physiology and pathology as difficult in the United States as it is to-day in England, where, thanks to a reckless agitation, research has been so hampered that resort must be had to the Continent for the merest facilities.

For our own part we believe that similar unreasonable agitations in our own country will be only sporadic, especially if everything done is done with the utmost openness and for some definite purpose. It should never be forgotten that for all teaching purposes and for most researches anaesthetics are invariably employed during what would otherwise be painful experiments. The cases are very few indeed, in which a suffering animal can be made useful: most of the ordinary experiments absolutely demanding the repose of unconsciousness as an essential condition. Knowledge of this fact should be more widely disseminated; and it should also be more generally known than it is that the ordinary appearances of a painful condition may exist when pain is absolutely out of the question. Perhaps along with the proposed compulsory education in the physiological effects of alcohol it might be well to inform the rising generation as to the effects of anaesthetics so that it would be possible for some, at least in adult life, to witness groans and struggles without jumping to the false conclusions that these of necessity prove the existence of "pain," "torture," "agony," etc., or that one who can witness them, and still remain calm, is necessarily inhuman or brutish.

#### MEDICAL NOTES.

—A somewhat unique agent for suicide is mentioned in *L'Union Médicale*. A workman placed a cartridge of dynamite between his teeth and exploded it. The effectiveness of the method was all that could be desired. We respectfully suggest it to Mr. Rossa's consideration.

—A test is suggested by Dr. Dulles, in *The Polyclinic* (February 15), for determining the character of the fluid discharged from a suspected salivary fistula. It consists in bringing a drop of the discharge into contact with a drop of the tincture of chloride of iron on a white surface—a piece of white paper will do—when, if the discharge contains saliva, it will give the pink color which indicates the presence of the sulphocyanide of potassium a normal ingredient of saliva.

—The *British Medical Journal*, in an editorial on the attempt on the life of O'Donovan Rossa, quotes the opinion of Dr. S. W. D. Williams, the eminent superintendent of the asylum at Hayward's Heath, where Mrs. Dudley was detained after her attempt on her own life in 1883. He describes Mrs. Dudley's

<sup>1</sup> By Drs. Richardson and Carpenter.

case as one of moral congenital insanity. She was not a woman subject to delusions; but it was owing to this perverted moral nature that she never evinced the slightest contrition for her attempts upon herself; nor is it likely—in the judgment of the medical men who have studied her case—that she will be in the least degree able to understand that in seeking the life of another she has been guilty of any wrong. In Dr. Williams's opinion, she would always be liable to a recurrence of the suicidal mania; and this, at any time, would be equally liable to be transformed into homicidal mania. Indeed, during the earlier period of her detention, she was both homicidal and suicidal.

—The Chancellor of the Diocese of York has written to the *London Times* that he has been asked to grant a faculty for a chancel, of which the specification prepared by an architect calls for the washing of the floor joists in a solution of arsenic out of a watering-pot, for the purpose of preventing "dry rot." That the architect appreciated the dangerous character of the substance used is shown by his instructions to the builder to wear a veil and gloves while performing the operation. The chancellor has refused the faculty until this item is withdrawn from the specification. It is said that, besides arsenical solutions, corrosive sublimate is also used for the purpose of preserving timber.

—That Paris is regaining somewhat of its former prestige as a centre of medical instruction, is shown by the figures published in the *Journal Officiel* of the number of enrolled students of medicine. In 1876 the number of such students in Paris was 1,927, and in 1883–84, 1,547, while the total numbers in France for the same years were respectively, 2,371 and 5,386. From the latter number should be deducted those who had taken all their courses and were waiting to complete their final examinations and theses, who were not enumerated under the former *régime*, amounting to about 1,500. This would make the actual increase in the students of medicine in these eight years some 1,515.

—A curious accident, the nature of which casts some light on certain explosions that have occurred in flouring-mills and similar places, and the cause of which was once looked upon as mysterious, occurred in a pharmacy in Strassburg. Whilst an apprentice was engaged in removing lycopodium from one vessel to another some of the powder became diffused through the atmosphere and igniting at a gas flame gave rise to a slight explosion. This so alarmed the young man that he dropped the vessel containing the lycopodium and a thick cloud of it spreading through the shop, a second and more violent explosion followed, which shattered the windows and blew the closed shutters into the street. The apprentice escaped with a few slight burns on the face.

—It is impossible, according to Mr. James Cantlie, in a lecture at the Parkes Museum, to find a pure Londoner of the third generation, that is to say, an individual whose two parents and four grandparents were all born and bred and continuously dwelt in London. It is rare to find an individual whose two parents, and three out of four grandparents fulfil the above condition; and such an individual is a very miserable, ill-developed specimen of the human race, of stunted growth, low stature, small head, and feeble intellect, destitute of any faculty of enthusiasm or humor, and very liable to scrofulous disease. England, Mr. Cantlie tells us, is constantly pouring into London a stream of healthy folk, whose offspring degenerate, so that the race quickly ceases to be. The upper middle classes, the professional classes, who take a long annual holiday, and whose children are generally educated at public schools in the country, are, of course, to be excluded from this generalization.

—The Paris correspondent of the *British Medical Journal* gives an account of an interesting suit of malpractice in which an action was brought by an *officier de santé* against M. Trélat, Professor at the Ecole de Médecine, and M. Delens, of the St. Antoine Hospital. M. Bouyer, the plaintiff, stated his case as follows: In the act of nailing down a box in May, 1883, he slightly injured the left forefinger. He sent for M. Piogey, his neighbor. M. Delens and M. Trélat were called in by M. Piogey; and the plaintiff complains that a number of operations were performed on him: that he was conducted to a *maison de santé*, and that M. Delens applied undiluted alcohol to his bleeding wound; that drainage-tubes were applied, and camphor-dressings bandaged on. After six weeks of daily agony, he left the *maison de santé* with a deformed hand. M. Bouyer accuses MM. Delens, Trélat, and Piogey of having treated and tortured him against his will, of having injured him by unskilful treatment, and names his damages at 20,000 francs (£800). M. Piogey declares that the plaintiff had a deep wound in the left forefinger, which required constant care day and night; symptoms of septicaemia soon appeared, and it was necessary to call in surgical assistance; very serious lymphangitis had set in, and several collections of pus had formed. The patient expressed gratitude for the care taken of him, and never opposed any part of the treatment, otherwise his wishes would have been considered. M. Trélat accepted the responsibility of having M. Bouyer removed to a *maison de santé*; his condition required it: he was in an almost hopeless condition, and could not otherwise have had the necessary attention given to him. M. Bouyer, the plaintiff, was condemned to pay damages of 3,000 francs (\$120) to each of the three defendants.

## Correspondence.

## OLD MEDICAL ANNOUNCEMENTS.

LEXINGTON, Mass., February 27, 1885.

MR. EDITOR,—In looking over some files of old journals recently I came across some items which may interest some of your readers. I therefore copied them and now enclose them herewith.

Yours respectfully,

ROBERT M. LAWRENCE.

[From the *Boston Gazette and Country Journal*, Monday, November 20, 1769.]

Doctor Anthony Duraeque Takes this Method to acquaint the Public. That he hath got an infallible Remedy and safe Manner of curing the following Disorders, viz: A When, the Fever and Ague, the Jaundice, the Scurvy, the Bloody-Flux, the Consumption if taken in time, the Pleuresy, the Dropsy, the Palsy, the Cancer and all manner of Sores and Ulcers: He also understands perfectly the operation of Fistula in anus (*sic*) and Fistula Lacrimale. He has also an excellent Balsam for the Pain in the Stomach and is very expert in curing all sorts of secret or Venereal Disorders, with the greatest secrecy and without any Confinement of the Patient. He also has an excellent Eye-water, which takes off all the Spots on the Eye-Balls. He hath met with great success both in England and France, being brought up and educated at Montpellier, and passed Examination before the best Physicians in France.

Any Person that will favor his Employ may hear of him at his Lodgings at Mr Piemont's, in King Street, opposite the Town-House.

[From the *Massachusetts Gazette and Boston News-Letter*, Thursday, January 28, 1768.]

We hear that a gentleman of a sedentary life, who has been long indisposed with indigestion and the hypochondriac passion, tried riding and several other sorts of exercises, but with little effect, was at last prevailed upon, by the advice of an eminent physician, to try being tossed in a blanket, which was accordingly performed every other morning for a fortnight and has been attended with the greatest success, the gentleman being now much better than he has been for two years past.

## Miscellany.

## ANTISEPTIC RECIPES.

The *Northwestern Lancet* has collected the following recipes for preparing catgut and animal drainage-tubes for the convenience of readers who may wish to prepare their own antiseptic materials:—

Lister now prepares catgut by immersion in a watery solution of chromic acid of the strength of one-tenth of one per cent. for twelve hours, and then in the solution of sulphurous acid of the British Pharmacopœia for twelve hours. The gut bend is dried and immersed in a bichloride solution prior to being used.

Delemer's method is to soak the catgut for forty-eight hours in a watery solution of corrosive subli-

mate, 1-1,000, and then keep in an alcoholic solution of same strength till used.

In the two methods above, the gut must be tightly wound on glass bottles weighted with lead before immersion in the watery solution, otherwise too much water will be taken up and the gut become soft and useless. Kocher's plan avoids the necessity of winding and is perhaps the best of all. He immerses the gut in oil of juniper for twenty-four hours, and then keeps it in alcohol till required for use.

In selecting gut two sizes are sufficient for most purposes: guitar E strings and violin E strings.

To prepare animal drainage-tubes, boil the long bones of a chicken or turkey well, then steep in a mixture of one part hydrochloric acid to two of water for ten hours, then wash them and trim with scissors. Finally, boil them in a five per cent. solution of carbolic acid and keep for use in the bichloride solution. Tubes prepared in this way will dissolve in a wound in from four to five days.

A convenient way of keeping a bichloride solution for use is to make an alcoholic solution of the strength of a drachm to the ounce. One drachm of this solution in a pint of water will give a 1-1,000 solution of the bichloride.

## RHEUMATIC GLOSSITIS.

AN interesting case of this disease is noted in *The London Medical Record* (January 15, 1885), as follows:—

J. L., aged forty, farmer, presented himself with symptoms of acute glossitis. The swelling of the tongue took place very rapidly, and in a few hours had become so great that the tongue protruded beyond the lips, which could not be closed. He breathed with great difficulty, and his face was cyanotic and pulse small. The saliva was abundant, and ran from his mouth, but the exposed surface of the tongue was dry and rough. Speech was impossible and deglutition nearly so. There were none of the usual causes to account for the inflammation, but the patient had suffered from rheumatism, and at present complained of pain in the shoulder and muscles of the neck. Six leeches were applied behind the angle of the jaw to give immediate relief. Before resorting to deep incisions, in the absence of the usual causes of this affection, and taking into consideration its abrupt onset and the rheumatic history, Dr. Carvallo prescribed four grammes of jaborandi leaves in infusion to provoke free salivation and perspiration, to be followed by six grammes of salicylate of soda, to be taken in three doses during the night. The effect of these remedies was remarkable, and in two days the patient was well.

## INCREASE OF CANCER IN GREAT BRITAIN.

MR. H. PERCY DUNN, writing in the *Pall Mall Budget* regarding English experience with cancer, gives figures from the forty-third annual report of the Registrar-General, showing the increase in the

mortality from this disease in Great Britain during the past thirty years. According to the report, 80,049 deaths from cancer occurred during the ten years from 1860-69 inclusive, and the annual average increase was 248. During the years 1870-79 the total number of deaths from cancer was 111,301, and the annual average increase was 320. As far, therefore, as numbers are capable of showing, we have here conclusive evidence of the incre-

ment in the mortality from cancer. It is observable also that the rate of increase is much higher in the latter than in the first ten years. It is, moreover, the case that the annual rate of increase is higher in the years 1860-69 than in the preceding decennium—namely, in the years 1850-59. In short, in the years 1850-59 the increment was about 2,000; in 1860-69, 2,400; in 1870-79, 3,200.

## REPORTED MORTALITY FOR THE WEEK ENDING FEBRUARY 28, 1885.

Cities.	Estimated Population.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 2,641; under five years of age 974; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrheal diseases) 336; lung diseases 531; consumption 408; diphtheria and croup 116; scarlet fever 10; measles 13; diarrheal diseases 42; erysipelas 23; malarial fever 23; typhoid fever 22; cerebro-spinal meningitis 15; whooping-cough 13; puerperal fever 8. From diarrheal diseases, New York 19, Brooklyn 9, New Orleans 5, Cincinnati and Buffalo four each, Philadelphia 4, District of Columbia 3, Charleston, Lowell, and Holyoke one each. From erysipelas, Philadelphia 9, Brooklyn 7, New York 4, Nashville, Cambridge, and Springfield one each. From malarial fever, New York 9, New Orleans 8, Brooklyn 4, District of Columbia 2, Philadelphia 9, Brooklyn 7, New York 4, Nashville, Cambridge, and Springfield one each. From typhoid fever, Philadelphia 8, Cincinnati 4, Boston and Buffalo two each, New York, Fall River, Salem, Lancaster, Middleboro', and Longmeadow one each. From cerebro-spinal meningitis, New York and Taunton three each, Philadelphia, Cincinnati, New Orleans, Providence, Nashville, Worcester, Fall River, and Holyoke one each. From whooping-cough, New York 6, Brooklyn and District of Columbia two each, Philadelphia, New Haven, and Holyoke one each. From puerperal fever, Brooklyn and New Orleans two each, Philadelphia, Boston, Huntington, and Dalton one each.

In 108 cities and towns in Massachusetts, with an estimated population of 1,345,152 (estimated population of the State 1,355,104), the total death-rate for the week was 20.76 against 18.25 and 20.57 for the two preceding weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,906,116, for the week ending February 14th the total death-rate was 20.9. Deaths reported 3,571; infants under one year of age 806; acute diseases of the respiratory organs (London) 383; whooping-cough 112; measles 91; scarlet fever 53; fever 11; diphtheria 35; diarrheal diseases 26; small-pox (London 31, Birmingham 3, Sheffield two, Liverpool one) 10. The death-rates ranged from 32.5 in Sunderland to 13.5 in Birmingham; Bedford 19.0; Hull 22.7; Leeds 19.1; Leicester 19.5; Liverpool 24.8; London 19.5; Manchester 22.9; Nottingham 21.7; Sheffield 22.0. In Edinburgh 15.8; Glasgow 20.7; Dublin 34.9.

In the Swiss towns for the week ending February 14th there were 54 deaths from lung diseases, consumption 21, diarrheal diseases 10, diphtheria and croup 8, measles 7, small-pox 5, whooping-cough, erysipelas, and typhoid fever one each. The death-rates were: at Geneva 20.2; Zurich 9.7; Basle 26.5; Berne 12.6.

The meteorological record for the week ending February 28th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Date.	Barometer.	Thermometer.		Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM FEBRUARY 28, 1885, TO MARCH 6, 1885.

BYRNE, CHARLES C., major and surgeon. Ordered to Department of the East on expiration of his present leave of absence, S. O. 50, A. G. O., March 3, 1885.

WOODRUFF, EZRA, captain and assistant surgeon. Ordered for duty at Fort Macinnis, Mont. T. S. O. 23, Department of Dakota, February 25, 1885.

EWING, C. B., first lieutenant and assistant surgeon. Having relinquished unimpaired portion of leave of absence, ordered for temporary duty in the field. S. O. 29, Department of Missouri, March 2, 1885.

RAYMOND, HENRY I., first lieutenant and assistant surgeon (recently appointed). Ordered for duty in Department of California. S. O. 50, A. G. O., March 3, 1885.

#### THE LATE SAMUEL A. FISK, M.D.

RESOLUTIONS upon the death of Dr. Samuel A. Fisk, of Northampton, adopted by the Hampshire District Medical Society.

*Whereas*, This Society, having recently lost by death one of its oldest and most honored members, who has held the offices of trust of the local Society, and that of President of the parent Society, we deem it just and fitting that official notice be taken of the departure of our esteemed associate. Therefore—

*Resolved*, That in the decease of our most respected brother, Dr. Samuel A. Fisk, we mourn the loss of a colleague of high intellectual qualities, of broad and general culture, a skillful physician and surgeon, whose heart was always in his work, of steadfast loyalty to the profession and unforgotten fidelity to his patients, an honored citizen, and a cordial friend in all the relations of life.

*Resolved*, That we hold him in pleasant remembrance as one who was an ornament and an honor to the profession to which he was devoted, and was so earnest to uphold, strengthen, and make subservient to the best interests of his fellow-men, as well as one to whom the Massachusetts Medical Society is indebted for his persistent efforts to preserve that Association from all encroachment by pretenders.

*Resolved*, That we extend our sympathy to his widow and family connections in their bereavement, and that a copy of these resolutions be sent to the family, by the Secretary, and that they be placed upon the records of this Society, and published in the local papers, and in the *Boston Medical and Surgical Journal*.

FRANKLIN HENRY,  
C. L. KNOWLTON.

#### SOCIETY NOTICES.

SUFFOLK DISTRICT MEDICAL SOCIETY, *Obstetric and Gynecological Section*. There will be a meeting of this Section in the lower hall of the Medical Library Association, 19 Bowdoin Place, on Wednesday evening, March 12th, at 7.15 o'clock. The following papers will be presented: Dr. John L. Sullivan, "Treatment of Abortion, with cases." Dr. J. R. Chad-

wick, "Seven Cases of Pregnancy and Labor complicated with Fibroids." Among those who will take part in the discussions are Drs. Sinclair, John Homans, Reynolds, Francis Minot, Boardman, Doe, Garland, Field, and J. W. Elliot.

JAMES R. CHADWICK, M.D., *Chairman*.  
ROBERT B. DIXON, M.D., *Secretary*.

RHODE ISLAND MEDICAL SOCIETY.—A quarterly meeting of the Rhode Island Medical Society will be held at Lyceum Hall, 62 Westminster Street, Providence, at ten o'clock, A.M., on Thursday, March 19, 1885. Dr. G. D. Hersey will read a paper on "Tracheotomy, with special reference to after-treatment." Dr. R. F. Noyes will open a discussion on "Typhoid Fever occurring during Pregnancy."

Candidates for fellowship are requested to meet the Board of Censors in the Medical Library at ten o'clock, A.M., on Tuesday, the 17th instant.

G. D. HERSEY, M.D., *Secretary*.

#### AMERICAN MEDICAL ASSOCIATION.

ARRANGEMENTS have been made to run a special train of parlor cars from Boston to New Orleans and return without change, for the accommodation of physicians and their friends who desire to visit that city during the session of the Association. The train will leave the Boston and Albany depot on Friday, April 24th, at 3 P.M.; Worcester at 4.20 P.M.; Springfield at 6.15 P.M.; Providence at 2 P.M., arriving in New Orleans, Monday, 27th, at 9 A.M. Arrangements will be made in advance for meals *en route*.

The fare for the round trip will be: From Boston, \$41.50; from Worcester, \$30.00; from Providence, \$31.50. From Springfield \$28. As the number of tickets will be limited, it is requested that all who intend to go should communicate with Dr. W. E. Anthony, of Providence, R. I., who will furnish tickets and any further information that may be desired. In order that requisite accommodations may be provided, applications to join the party should be made before April 20th.

#### CORRECTION.

MR. EDITOR.—Will you kindly allow me to correct an error in my report of the proceedings of the Obstetrical Society of Boston, which appeared in the *JOURNAL* of February 26th, page 203?

In the discussion on Dr. E. J. Forster's paper on "Pelvic Abscess following child-birth," Dr. Baker's remarks should read as follows: Dr. Baker said that the effusion was first inspired to establish the diagnosis; then, using the aspirating needle as a director, Dr. Forster opened the abscess with a long, narrow-bladed bistoury sufficiently to admit the finger.

Yours truly, C. M. GREEN.

#### RESIGNATIONS.

DR. FRANK W. PAGE, who has been resident physician at the Adams Nervine Asylum since the opening of that institution five years ago, has resigned, to engage in private practice.

MASSACHUSETTS GENERAL HOSPITAL. Dr. F. Gordon Morrill has resigned the position of physician to out-patients.

## Lecture.

THE TUBERCLE BACILLUS: ITS MORPHOLOGY, MODE OF DETECTION; ITS LIFE HISTORY. ITS RESULTS IN THE HUMAN ORGANISM. THE CULTURE OF THE TUBERCLE BACILLUS.<sup>1</sup>

BY PROFESSOR GERMAIN SÉE,

Physician to the Hôtel Dieu, Paris, France.

AMONG the microphytes the one which interests us the most, because, although hardly discovered more than two years, it is now the best shown, the most clearly characterized, is the tubercle bacillus.

## HISTORY.

Several years before the discovery of the bacillus, Klebs had already announced that he had succeeded in isolating the bacterium of tuberculosis, in cultivating this microbe in an albuminous liquid, and in producing, both by inoculation and intra-peritoneal injection, the same lesions as the primordial tubercle containing the same bacteria.

The researches of Klebs were verified in 1879; the same inoculations were performed by Schneller and Reinstadler in Germany, by Toussaint in France, and in 1881 by Deutschmann, who, however, did not succeed in reproducing phthisis, except by taking the precaution to add to the culture-liquid solid particles of tubercle; in reality all that these experiments really accomplished was the inoculation of common bacteria and the production of ordinary non-specific lesions having the appearance of tubercle. The bacteria with micrococci, indicated by Aufrecht, were not attended with any better success.

*Zoöglea*.—At the same epoch Rindfleisch and the same Aufrecht believed that they had found, in the centre of tubercle, in the well-known segments known as giant cells, the microphytic masses which we have indicated under the name of *zoöglea*. Renault, of Lyons, attributed to them a certain importance in the composition of tubercle, and more recently Malassez and Vignal have cultivated and inoculated these *zoöglea*. It was found that in the third generation of microphytes resulting from this injection of *zoöglea*-liquids the living products of culture returned to the bacillus-state; they would then seem to be only a transitory form of the bacillus.

*Bacilli*.—Bacilli were indicated as causal by Baumgarten; he, however, did not know how to render them evident. It was Koch who first, by a special process of staining, succeeded in demonstrating these microphytes. In the month of April, 1882, he communicated to the Medical Society of Berlin the results of these researches, and proved in an unmistakable manner that in the tuberculous organs of man there exist certain rod-shaped corpuscles which, by their chemical and morphological properties, differ totally from all other known forms of microphytes; these are the bacilli of tuberculosis.

## DESCRIPTIVE CHARACTERISTICS.

These bacilli are very thin rods, whose length scarcely equals the quarter or the half of that of a

red blood corpuscle; they resemble, principally by their form, the bacilli of lepra, which are rather finer and more pointed.

Among the bacilli spores are sometimes found; that is to say, fine, round, and refractive corpuscles. Along with them, moreover, you will sometimes see the gelatiniform masses known under the name of *zoöglea*.<sup>2</sup>

## TECHNIQS.

1. *Koch's Method*.—The bacillus cannot be detected except by the methods of staining invented by Weigert and perfected by Koch, who has demonstrated that the bacillus, once colored by methylene blue, resists coloration by vesuvine, while other microphytes contained in the preparation lose their blue color to take on the brown tint of the second coloring agent.<sup>3</sup>

2. *Ehrlich's Method*.—Ehrlich proceeds quite differently. He had remarked that Koch's bacillus when impregnated with an aniline color resists the action of dilute nitric acid, while all the other elements, microbes, and cells are speedily decolorized. Ehrlich employs Weigert's solution, of which the composition is as follows: "Take of saturated aqueous solution of aniline oil 100 cc.; saturated alcoholic solution of fuchsine 11 cc. Mix for the coloring solution." "The tissue or sputum to be examined is spread in a very thin layer over a thin glass cover, and is then dried in the air. It is then passed a few times through the flame of a spirit-lamp to coagulate the albumen. The glass cover, thus prepared, is placed for twenty-four hours in a watch-glass containing the staining liquid. It is then washed with distilled water, then with a thirty per cent. solution of nitric acid till all the color comes away. Then it is again washed in distilled water, then dipped in an aqueous solution of methyl blue. The preparation is then dried and mounted in Canada balsam. It shows the bacilli of a brilliant red color, the cells with their nuclei, and the other microbes being stained blue." — (Talamon.)

This procedure, modified by Rindfleisch, who slightly heats the staining liquid to hasten the coloring of the bacilli, has received the approbation of Koch himself.<sup>4</sup>

Numerous variations have been introduced into the techniques of the preparation, which concern especially one of the elements of the staining liquid. Thus, sulphates and chlorides of rosaniline have been proposed, and divers methyl violets, alone or

Rindfleisch, Malassez, Renault.

Koch's method is as follows: Dry a small piece of sputum on a glass slide, place it in a weak alkaline methylene-blue solution for twenty-four hours, and then wash the preparation with vesuvine.

TRANSLATOR.

<sup>1</sup> Gibbs, in the London Lancet, May 5, 1883, page 771, gives the following ready process, the great advantage of which consists in doing away with the use of nitric acid. The stain is made as follows: Take of rosaniline hydrochloride two grammes, methyl blue one gramme; rub them up in a glass mortar. Then dissolve aniline oil 5 cc. in 10 cc. of water, add the dye, and the solution is ready for use. The slide is dissolved, then add distilled water 5 cc., keep in a stoppered bottle. To use the stain: The sputum having been dried on the cover-glass in the usual manner, a few drops of the stain are poured into a test-tube and warmed, as soon as steam rises pour into a watch-glass and place the cover-glass in the staining fluid. Allow it to remain four or five minutes, then wash in methylene-blue till all no more color comes away, drain thoroughly and dry, either in the air or over a spirit-lamp. Mount in Canada balsam. The whole process after the sputum is dried need not take more than six or seven minutes. This process is also valuable for sections of tissue containing bacilli, as they can be doubly stained without the least trouble. In this way beautiful specimens have been made without the shrinkage which occurs in the nitric acid process. (Brathwaite's Retrospect, Part 88, page 221.) TRANSLATOR.

<sup>1</sup> Translated by E. P. Hurl, M.D.

mixed, always diluted in an alcoholic solution of aniline. Frankel has just added certain improvements; he stains a second time to render the coloring stronger and more durable.<sup>5</sup> I have always adhered to the method of Ehrlich, which is the most employed and the most sure.

#### BIOLOGY OF THE BACILLUS. ITS PARASITE LIFE.

Under the name of tuberculous organisms I shall include only the specific bacilli; no other parasites produce the characteristic lesions.

Now the bacillus is found not only in true phthisis, but also in individuals called scrofulous, affected with divers bony, glandular, cutaneous diseases. It is also met with in a great number of tumors heretofore undetermined, which occupy the peripheral organs or even the viscera, in individuals to all appearance perfectly well and exempt from every scrofulous or tuberculous taint. It remains to mention the bacilli in connection with the disease which rages among cattle under the name of bovine phthisis.<sup>6</sup> I shall return to this subject when I come to speak of the flesh and milk of these animals.

**I. Tuberculosis. Divers Lesions.**—The bacilli are found in the divers forms of the tuberculous process, whether this be localized in the lungs, or whether it be at the same time disseminated throughout other organs. When the principal if not only seat is the lungs, the bacillus characterizes the first as well as the more advanced periods of the disease. It is also found in the lesions called granulations, miliary tubercles, as well as in the destructive caseous and ulcerous stage. In all cases it has its seat of procreation, though not its exclusive seat, in the tubercular elements called epithelioid cells and giant cells, where, too, the necropsy reveals it.

**Products of Secretion, Sputa.**—During the life of the patient the microphyte is recognized with the same facility and with the same certainty in the products of expectoration as in the dead elements. The presence of the bacilli in the sputa constitutes, from the most insidious beginnings of the disease, from the first excretion of a formed sputum, the certain, irrefutable sign of the disease, as I shall show at some length when I come to treat of the signs and of the diagnosis of that form of phthisis which I shall call *latent* because it has no certain sign, and of that form which I shall designate under the name of *lurated* because it takes the mask (Latin, *larva*) of another disease.

**Urine, Urine Matters, Blood.**—The sputa are the only excreted products which constantly contain the bacilli; the urine and faecal matters contain them only in exceptional cases, where there is tuberculous disease of the genito-urinary organs or intestines. As for the blood, it does not constitute a habitual or favorable receptacle for the bacillus.

**II. Tuberculosis; first Local, then General.**—The phthisiogenic microphytes are found in all organs which are invaded by disseminated tubercle. Suppose, for instance, a case of pulmonary tuberculosis at first distinctly circumscribed; from this central focus the bacilli, undergoing multiplication, may penetrate by irruption the blood vascular or

lymphatic system, and produce general, so-called, miliary tuberculosis. Now in these miliary tubercles, found so often in the meninges, pleura, peritoneum, liver, kidneys, etc., you will discover the bacillus, though in less quantity than in the tuberculous products—more or less advanced—of the lungs.

**III. Local Tuberculosis.**—It is the same with localized tubercles which remain localized like those of the genital organs; the bacillus exists there, though relatively in small quantity. It is in bacillomas of this kind that you often note spontaneous and thorough cure.

**IV. Scrofulus in General.**—In the organisms of patients who are called scrofulous—neither the disease, however, nor the predisposition nor the constitution being well defined—you will often find the bacillus, whose identity with the tubercle bacillus proves also the identity of scrofula and tuberculosis.

**Scrofulous Adenitis.**—Also in indurated scrofulous glands you frequently observe the caseous degeneration which we are soon to describe in connection with tuberculous, called caseous, pneumonia. In the caseous mass the bacillus exists constantly, so that its very presence enables you to affirm the localized degeneration to be of tuberculous nature.

**Scrofulous Osteitis.**—In bones affected with osteitis, with periostitis, with white swelling, with chronic fungoid arthritis, the dominant lesion is tubercle, and the presence of the bacillus is constant.

**Lupus.**—Cornil has met with bacilli, few in number it is true, but constantly, in lupus, which ought henceforth to enter into the category of scrofulo-tuberculous affections. In fact, Besnier has with great sagacity shown that, in the Hôpital Saint Louis, lupus compromises life by the tubercles which it develops in the viscera, and especially in the lungs.

**V. Circumscribed Tubercles of different Organs.**—It is not necessary that the lesions above indicated should be grafted on a "scrofulous" stock; we often see localized and curable tuberculous of the genital organs in healthy men and women. The affections of certain mucous membranes, such as the pharynx, mouth, the larynx, often manifest themselves by the lesions whose exact nature is not obvious till microscopic examination is made of their products; the presence of bacilli shows clearly their tuberculous nature.

**VI. Local Tuberculous becoming Infectant.**—Do not forget that the circumscribed tuberculous foci of bones, of the genital organs, etc., may, as well as those of the lungs, become all at once the point of departure of a real infection which spreads to the important vital organs. After a long series of years of quiescence the tuberculous foci may, without known cause, discharge into the blood colonies of bacilli which invade and ravage the entire organism. This is the familiar history of those acute phthisical maladies which take their start in a bacillary centre almost or quite forgotten.

#### THE CULTURE OF THE MICROPHYTES, AND ESPECIALLY THE TUBERCLE BACILLI.

**Culture-Liquids.**—The specific microphytes develop with difficulty in the atmosphere, more readily

<sup>5</sup> Society of Berlin, March, 1881.

<sup>6</sup> Pouchet, etc.

in inert substances, and still more readily in living organisms, their ordinary habitat. Where derived by the organism from without, it is by divers channels of absorption, especially by the respiratory mucous membrane and the alimentary canal, introduced by air and food, that they penetrate the economy. They then localize themselves and form a circumscribed focus, or multiply, carried along by the blood current in different parts of the organism. Now in these primitive foci, circumscribed or multiple, or in the blood itself, the microphytes can be obtained, transported to a nutrient liquid, and cultivated without losing their deleterious properties. It is only by a long series of cultures in nutrient liquids constantly renewed, or even by free access of air, that their pathogenic power diminishes.

*Composition of Culture Liquids.*—The most nutritive substances for the pathogenic parasites are not the albuminous groups, but the gelatinous compounds, glutine, chondrine, without doubt also mucine. You may advantageously use for cultures solutions of gelatine or decoctions of meat-containing gelatine. In other culture-fluids destined for the bacteria of putrefaction the pathogenic bacteria lose their properties and their forms.

These gelatinous media present themselves naturally, under suitable conditions, in the soil and in stagnant waters. But cadavers and organic matters undergoing putrefaction at the surface of the earth, form a bad culture medium for the specific microbes, because these soon lose by access of air their pathogenic power, and in the second place because they are soon replaced by the septic forms.

*Culture at a certain Temperature.*—This substitution takes place the more quickly the less the surrounding temperature is favorable to the pathogenic microbes, and the better it suits the septic forms. Thus it is demonstrated that the specific microbes can only develop in a temperature above  $25^{\circ}\text{C}$ ., from this up to  $41^{\circ}\text{C}$ ., while the fungi of putrefaction vegetate between  $16^{\circ}$  and  $20^{\circ}\text{C}$ ., and multiply at  $15^{\circ}\text{C}$ .

#### CULTURE-LIQUIDS OF THE BACILLUS TUBERCULOSIS.

At first Koch tried gelatine (extract of meat, peptone, and gelatine) without success, and this for the good reason that the bacillus cannot thrive at a temperature of  $20^{\circ}\text{C}$ ., above which gelatine melts. He bethought himself then of coagulated and sterilized blood serum, which may be made to furnish thin transparent layers. You heat the blood (of beef or mutton) for six days, every day one hour at  $58^{\circ}\text{C}$ ., then several hours at  $65^{\circ}\text{C}$ ., till the serum remains coagulated. On this culture-field you sow bacilliferous-tubercle fragments, which are then exposed in a suitable covered receptacle to a constant heat of  $37^{\circ}\text{C}$ . About the tenth day there form on the surface of the liquid minute scales and little points; after several weeks the growth of the bacillary colony, often appearing contorted like the letter S, is finished. The bacilli thus nurtured are often passed through eight or ten cultures before serving for infection, inoculation, or inhalation experiments.

### PREMATURE BIRTH FOLLOWING THE SUCCESSFUL TREATMENT OF MORPHIA-POISONING BY ATROPIA.<sup>1</sup>

BY EDWARD J. FORSTER, M.D.,  
Visiting Physician to the Boston City Hospital.

This case is of interest to the therapist on account of the amount of atropia used to antagonize the morphia and to the obstetrician (which is my reason for reading it to this Society) on account of the premature delivery which followed, and also that a *living* child was born after the mother's system had been so thoroughly affected by the morphia as to reduce the respirations to two a minute.

Sunday, September 7, 1884, having finished my morning visit, I was about leaving the hospital at 1.10 p.m., when a young married woman of twenty years was brought in by her husband in an unconscious condition, with the statement that she had swallowed thirty grains of acetate of morphia. The patient was in a state of collapse, the pupils contracted to the merest pinholes, and the respirations very slow. By my order half a grain of sulphate of atropia was immediately given subcutaneously. A physical examination was then made. The patient was unconscious, the pupils contracted, not reacting to light. The heart, lungs, and abdominal organs were found to be normal. The uterus was found to be extending above the umbilicus one third the distance to the ensiform cartilage.

Dr. W. L. Richardson, who had accompanied me on my visit, was present, and was able to hear the fetal heart faintly, above the left groin, beating eighty times to the minute. The temperature was  $98.6^{\circ}$ , pulse 72, respirations 7. Another injection of one fourth of a grain of sulphate of atropia was then given, which was followed by dilation of the pupils.

The following history was obtained from the husband: The patient had been married two years and three months; had a child eighteen months old; last menstruation ended March 10th; not in the habit of taking either opium or alcohol. General health good, except morning sickness during pregnancy. Has seemed somewhat dispirited for last few days, but was singing happily when he left in the morning. At eleven o'clock he was sent for to come home to dinner, as his wife did not feel well; being the only clerk in a drug-store, he could not leave, but sent home a Seidlitz powder. Going home at 12.15 he found his wife lying on the sofa; she had a peculiar look, said she had taken something wrong, and told him to look on the table; there he found a two-drachm bottle labeled morphia, acetate, and poison. He thinks there must have been nearly a drachm in the bottle, as that amount had been put in and but little had been used. Thinks his wife must have mistaken it for a bottle of quinine of similar size and shape. She complained greatly of thirst, and was anxious to lie down. He walked her about for seven minutes, then gave her wine of antimony, which caused her to vomit slightly, afterward mustard-water, which made her vomit freely. She soon became unconscious, did not respond to slapping,

<sup>1</sup> Read before the Obstetrical Society of Boston, November 8, 1884.

Dr. J. G. Blake was called, by whose order she was brought to the hospital.

It is supposed she took the morphia at 11 o'clock, A.M.

At 1.30 o'clock the stomach was washed out and a pint of hot black coffee was poured in through the stomach-tube, and artificial respiration resorted to. A subsequent examination of the fluid from the stomach showed no trace of morphia.

At 1.45 the pulse was 150, respirations 4, pupils dilated; flagellation was tried; this caused the patient to struggle, but did not arouse her to consciousness; this was continued constantly for half an hour, then interrupted for another half-hour. The faradic current was applied to the phrenic nerve, but without much apparent effect.

At 2.15 pulse 144, respiration 7; some quivering of muscles of neck and chin noticed.

At 2.30 temperature 99, pulse failing; ten grains of carbonate of ammonia were given subcutaneously.

At 3, pulse 136, respirations 2; enema of three ounces of brandy were given.

Artificial respiration was kept up continuously for one and a half hours.

At 4, pulse 120, respiration 6; one fiftieth of a grain of sulphate of strychnia was given subcutaneously as a stimulant to the respiratory centres.

At 5, pulse 125, respiration 5; cries when slapped.

At 6, pulse 120, respiration 6; enema of brandy, three ounces.

At 8, pulse 128, respiration 10; had involuntary dejection, and asks for drink.

At 10, pulse 124, respiration 11; talks, and drinks milk.

At 2 A.M., Monday, pulse 122, respiration 18; some twitching of hands and arms.

At 6 A.M., pulse 116, respiration 28; she vomited. During the night she took four pints of milk.

At 9 A.M., she was quiet and comfortable, but very thirsty, legs tender, swollen, and discolored from the flagellations.

At 11 o'clock, while making the morning visit, an accumulation of fecal matter and liquid, which proved to be liquor amnii, was found in the bed. Before a vaginal examination could be made, she uttered a sharp cry and gave birth to a six months male fetus, breech presentation, the head being delivered without difficulty. The third stage was completed by Credé's method in about three minutes. The convalescence was nearly normal.

The secretion of milk in the breasts was checked by belladonna ointment locally and one-sixtieth grain doses of atropia internally.

The child breathed a few times immediately after birth; he was placed in hot water, then in hot cotton, and artificial respiration continued for half an hour. The respiration and pulse grew slower and feebler, until both ceased thirty minutes after birth.

The child was well-formed, fifteen inches long; one testicle could be felt in scrotum, pupillary membrane still present. Battledore placenta with cord attached to membranes for a distance of ten inches.

An abscess formed at the site of the subcutaneous injection of carbonate of ammonia.

After suffering from a boil on each buttock, several small ones about the neck, and an abscess over the tibia which required opening, the patient was finally discharged well, on the 27th, twenty days after entrance. The foregoing account is abstracted

from the careful records kept by James B. Field and James A. Gage, house officers.

The accompanying chart shows at a glance the effects of the drugs upon the pulse and respiration.

I gave the large amount of atropia, having in mind a case which I had recently read, in which, by Dr. Fothergill's direction, a grain was injected and a woman's life saved who had taken a very large amount of laudanum.

At the time I thought I was giving a lethal dose, but Wharton and Stillé, in their last edition, state that while one-sixth grain has caused alarming

symptoms, a grain has not caused death.

If labor had not occurred in this case after all the woman had undergone, I should have been surprised, but to which particular agent to attribute it I am at a loss.

## UNINTENTIONAL ARTIFICIAL RIPENING IN A CASE OF ZONULAR CATARACT.<sup>1</sup>

BY HASKET DERBY, M.D.

It is generally maintained that zonular or lamellar cataract cannot be made to extend over the whole area of the lens by either of the methods now in use for the artificial ripening of senile cataract. In a recent number of the *Boston Medical and Surgical Journal*, Dr. Wadsworth gives the following statement, as representing the views of the authorities he has reviewed: "For posterior polar cataract, and perhaps also for lamellar cataract, Foerster's method is not efficient."<sup>2</sup>

No less an authority than Jakobson has very recently published the following assertion. Speaking of the effect of an iridectomy alone on the formation of cataract, he says: "Distinct opacity is found neither in the case of the transparent lens, nor in zonular cataract, even when cortical striae are to be found between the opaque layer and the anterior capsule."<sup>3</sup>

An instructive commentary on the above statements is furnished by the patient before us. She is twenty years of age, and the subject of congenital zonular cataract, each eye being affected. No family history of trouble with the eyes exists, the parents having excellent sight, as also her several brothers and sisters. The mother states that, in

<sup>1</sup>Notes of a case exhibited to the New England Ophthalmological Society, February 3, 1885.

<sup>2</sup>Vol. cxli., No. 4, page 84.

<sup>3</sup>Archiv für Ophthalmologie, Bd 30, Abth. B, S. 268.

the third month of her pregnancy she was assaulted by a crazy woman whose eyes had been diseased and had a very peculiar appearance; and that the expression of these eyes made a powerful impression on her at the time. (This statement is of course given for what it is worth.) In a bright light the entire area of this patient's pupil was occupied by the opaque lens, and vision under these circumstances was so imperfect that the patient has, for six years past, been an inmate of a blind asylum. Under atropine the cataract was seen to be not sharply defined, but to be surrounded by little opaque prominences, these bearing the same relation to the lens that the corona, during an eclipse of the sun, does to the disc of the latter. The whole interior of the eye could now be seen, and appeared normal. With the pupil thus dilated vision greatly improved, rising to one tenth in the right eye, two tenths in the left. I had therefore no hesitation in earnestly advising an iridectomy on both eyes, but received permission to perform it only on the right or worst. This was done under ether December 22, 1884; a new pupil being formed downward and inward. Although the incision caused no hæmorrhage, the excision of the iris was followed by an unusual amount of bleeding into the anterior chamber, about a third of which was filled. I should say that there was no suspicion of a dialysis, the iris not even prolapsing at the time of the corneal incision, but remaining in place until gently grasped by the forceps. The blood thus left in the chamber was readily absorbed, the bandage was omitted after the third day, and the result has been satisfactory, vision being nearly doubled, and the patient now reading coarse print with this eye in all lights.

December 28th, a similar operation was performed on the left eye. Every step in it was taken without difficulty and in the usual manner, but profuse hæmorrhage followed the excision of the iris, completely filling the anterior chamber, and only ceasing on the application of ice. Attempts were then made to remove the blood by depressing the lip of the wound, and gently smoothing over the face of the cornea with a flat flexible rubber spatula, and were partially successful, a thin layer of blood remaining behind. On the 31st, the clot was confined to the area of the pupil, and atropine was now applied, but failed to bring about any dilatation for two days more. Finally all the blood absorbed, the pupil enlarged, and the cataract was now discovered to have invaded the entire lens, extending to its periphery. View of the fundus was entirely cut off, and vision reduced to one twenty-fifth.

That this cataract has been ripened, either by the iridectomy or the attempts to remove the blood from the anterior chamber, cannot be doubted. I propose to operate on it by discission this coming spring.

— By a new treaty between Great Britain and China, the control heretofore exercised by the former government over the internal tariff of the Chinese Empire, with reference to the importation of opium, is abrogated, and China is to have complete freedom of taxation of the drug.

## REPORT ON PUBLIC HYGIENE.

BY S. W. ABBOTT, M.D.

## SEWERAGE AND SEWAGE DISPOSAL.

PROF. HENRY ROBINSON, in a recent paper on sewage disposal, deduces the following conclusions:—

(1) That chemical precipitation is not so necessary now as it was considered to be a few years ago in cases where land for irrigation is not procurable.

(2) That the efforts to profitably remove the manurial elements from sewage by chemicals not having been successful, the system should be adopted *per se* only when a filtration-area cannot be obtained.

(3) That the success which has attended the construction of filtration-areas where the land is clayey, and the results which have been obtained from a combined straining of sewage and of subsequent filtration through small areas of artificial filters, point to the adoption of one or other of these systems in many cases, when chemical treatment would previously have been advised.

(4) That the injurious effects of passing untreated sewage into a river depend not merely upon the relative volumes of the sewage and the river, but chiefly upon the power of the river to oxidize the sewage, which power is in proportion to the extent of oxidation of the river itself.<sup>1</sup>

The Parliamentary Commission who were directed to report upon the present system of sewerage of London, "whether any evil effects result therefrom, and in that case what measures can be applied for remedying or preventing the same," have rendered their second and final report, which is especially valuable, as giving in concise and terse form their summary of opinions as to the comparative value of the various modes of sewage disposal, in their general application, as well as to the special needs of the Metropolitan Board of London.

A brief historical *résumé* is given of the various reports and investigations upon this subject from 1856 to 1881. Special reference is made to important decisions with reference to the discharge of sewage into the river Lee by the corporation of Hertford, and also as to the scheme of the Lower Thames Valley Sewerage Board, a plan involving partly the system of broad irrigation and partly that of intermittent filtration.

The subjects of the separation of the sewage from the rainfall, and also the prospect of profit by the utilization of sewage, are both treated in the preliminary portion of the report, and while the separate system is endorsed as worthy of consideration in future extensions of drainage, the commission are of the opinion that the "expense, trouble, and annoyance would make it impracticable now to apply to the Metropolitan drainage generally the system which was rejected when the present arrangements were made."

As to the profits of utilization of sewage, they also affirm that "there can be no doubt that the preponderance of the evidence is against the idea that the sewage of the metropolis can, at present,

<sup>1</sup> Paper read at the Dublin meeting of the Sanitary Institute of Great Britain, October 2, 1884.

be applied by irrigation so as to be a source of profit to the rate-payers."

Looking now to the whole of the evidence we have obtained on the prospect of profit from the utilization of sewage, we are of opinion

(1) That the most likely mode to obtain a profit from the utilization of sewage is by irrigation; but that, in the present state of knowledge of the subject, there is no hope of any town doing so consistently with the due attainment of the more important object, the purification of the sewage. In some very favorable cases (as in Edinburgh), a profit may be made without purification, and very frequently the purification may be effected without profit, but the two cannot apparently be combined.

(2) There is still less hope of profit by attempting to extract manure from the sewage by depositing or precipitating processes; the available manurial value of the sewage is at present too small to admit of obtaining from it any product which can be sold at anything like the cost of its production. Considering the small theoretical value of the sewage, twopence per ton at the most, and seeing, moreover, that its chief manurial value lies in its soluble constituents, it is not probable that any mode of abstracting from it a marketable manure can be devised. The only possibility is that the precipitated matters might be made to yield some little return in diminution of the cost, and even this appears at present uncertain.

(3) But the question before us is not an abstract one, not whether in some places, with some land, and with some amount of sewage, a profit can be made. The question is whether London sewage can be so dealt with, and we consider the circumstances altogether unfavorable.

(4) Looking, however, to the fact that sewage does contain elements of value, and that the aggregate value of Metropolitan sewage is undoubtedly very large, we think the possibility of realizing some of the value should be borne in mind in devising plans for its disposal. And it is clear that our present knowledge points to the application to land as the most probable mode by which this can be done.

(5) But we are strongly of the opinion that it would be wrong to delay proceedings on this account, and that freeing the Thames from pollution must be undertaken as a work to be done and paid for, whatever the cost may be.

The various plans considered by the commission may be summed up as follows:—

(1) Broad irrigation.

(2) Filtration.

(3) Deposition or chemical precipitation.

(4) A combination of (3) with a subsequent complete purification of the classified sewage by applying it to land.

(5) Removal of the outfalls farther down the river.

(6) Removal of the outfalls to the sea.

*Broad irrigation* is considered with reference to its efficiency, its liability to objection, and its cost, and in summing up this method the opinion of the commission is thus given:—

(1) Generally speaking, it offers a satisfactory mode of disposal of town sewage, when circumstances admit of its application.

(2) It offers the most likely means of realizing some portion of the value of the sewage.

(3) When properly arranged, and carefully conducted, the effluent will be effectually purified, but that under careless management the purification may be incomplete.

(4) It need cause no danger to health.

(5) With proper care, when applied on a moderate scale, it need cause no serious nuisance to the surrounding neighborhood, but that if improperly managed nuisance may arise and may become considerable.

(6) There may be a danger of the pollution of subsoil waters.

(7) To apply broad irrigation to the Metropolitan sewage near the outfalls would be a matter of great difficulty, on account of the enormous quantity of land required, its great probable cost, and the powerful opposition that would be raised against such a proposal.

(8) For these reasons, we do not recommend any attempt to apply this system as a remedy for the evils of the Metropolitan sewage discharge. We say nothing of such an attempt if it could be made by private enterprise.

With regard to *Filtration* the following conclusions are given:—

(1) The process has great scientific merit, and offers valuable practical advantages for the disposal of sewage in situations where broad irrigation is impracticable, and where land suitable for filtration can be obtained.

(2) It appears desirable, when the area of land is considerably reduced, that the sewage should be previously treated by some efficient process for removing the sludge.

(3) An arrangement of this sort would be applicable to the metropolis.

As to *Chemical treatment*, the various modes are briefly reviewed, as also the treatment of the sludge, its quantity, and the cost of various processes, with the following conclusions:—

(1) The adoption of a process of this kind would effect an improvement on the present state of things. It would diminish the nuisance, and it would lessen the tendency to deposit foul banks and shoals.

(2) Precipitation alone would not effectually purify the river; some nuisance would probably still occur in dry seasons; and the injury to fish and danger to wells would in some degree still remain.

(3) The works might be carried on without sensible nuisance.

(4) The cost would be at least £200,000 a year, or about one shilling per head of the population.

(5) It would result in the loss practically of a large part of the manurial value of the sewage, offering no prospect of its future realization unless the clarified liquid was afterward applied to land.

(6) Several processes appear to be fairly effective, but there has been no evidence to satisfy us of the marked superiority of any one in particular.

(7) It could be brought into action much more quickly than any other remedy.

(8) In case of its being disused, it would entail but a comparatively small pecuniary loss.

Of the *combination of precipitation with the sub-*

sequent application of the impure liquid to the soil by filtration, as related to the treatment of the Metropolitan sewage, the commission conclude that this plan offers one of the most feasible means of solving the difficulty.

As to the two remaining plans, the removal of the outfalls to a lower point upon the river, and also the removal to the deep sea, the commission pronounce an unfavorable opinion, especially with reference to the latter.

On the other hand, the testimony of Mr. Baldwin Latham before the commission was as follows: "I am of opinion that it would be far cheaper to spend five or six millions of money in carrying an extended outfall into the deep sea, than to carry out any precipitation process."

In fine the general conclusions of the commission, and the recommendations offered, are:—

(1) The evils of the present system of sewage discharge imperatively demand a prompt remedy.

(2) It is neither necessary nor justifiable to discharge the sewage of the metropolis in its crude state into any part of the Thames.

(3) Some process of deposition or precipitation should be used to separate the solids from the liquid sewage.

(4) Such process may be conveniently and speedily applied at the two present main outfalls.

(5) The sludge can be used for the raising of low lands, or burned, or dug into the land, or carried out to sea.

(6) Any process adopted must be conducted as much as possible without nuisance.

(7) The liquid portion of the sewage may, as a temporary measure, be allowed to run into the river.

(8) Its discharge should be limited to the period between high water and half ebb of each tide.

(9) Much evil will thus be abated.

(10) The discharge of the liquid portion of the sewage should not be a permanent measure.

(11) Intermittent filtration is advised for the liquid portion, which should be pumped from the separating works to elevated land for further purification.

(12) The sewage of the south side of the river to be conducted across, if land cannot be found suitable for the purpose on the south side.

(13) If no land can be obtained near the present outfalls, it is further recommended that the liquid portion after separation be carried further down the river, as far as Hole Haven.

(14) In the latter case, the main conduit may be made sufficiently large to admit of the extension of the drainage system to the outer districts of London. In such districts the separate system to be adopted.<sup>2</sup>

#### OFFENSIVE TRADES.

The twentieth annual report of the chief inspector<sup>3</sup> under the British Alkali Works Acts states that there were, at the close of 1883, 920 works which properly came under the supervision of the inspector in England, Scotland, and Ireland. These

included works for the production of sulphuric and nitric acids, chemical manures, sulphate of ammonia, pottery, salt, and other products.

In the artificial-manure works the processes employed are quite efficient, the offensive gases being conducted through cooling shafts and tall water-towers, and are finally burned in the furnace fires.<sup>4</sup>

Certain improvements have been effected in the modes of preventing nuisance from sulphuretted hydrogen in the manufacture of sulphate of ammonia: first, by burning the gas and forming sulphur; second, by absorbing it by means of oxide of iron purifiers.

Dr. Smith recommended as a limitation of allowable acidity of the gases finally escaping from these two classes of works .2 of a grain per cubic foot of sulphuric anhydride for the former (manure works) and .5 of a grain for the latter (sulphate of ammonia works).

#### FOOD INSPECTION.

The latest report of the Local Government Board gives the following summary with reference to the Food and Drugs Act and its operation.

The number of samples analyzed has considerably increased, while the proportion found to be adulterated remained about the same during the past few years; but the adulterants employed were found to be far less dangerous to health.

The whole number of analyses made during the year was 19,648, and the cases in which adulteration was proved were 2,955. By far the greater number of samples were obtained by the local officers. The proportion of articles adulterated was much greater in those which were brought by private consumers for analysis, since few private individuals care to enter complaints, unless their suspicions have been quite strongly aroused. The articles selected for analysis were mainly milk, spirits, butter, coffee, and bread. Adulterations in all these articles except bread were quite common. Of the latter, 1,013 samples out of 1,013 were found to be pure. Of adulterated drugs 50 samples were found to be deficient out of 301.

The Local Government Board estimate that between \$70,000 and \$80,000 is annually paid in London for water sold under the name of milk. Beer and wine were less liable to fraud than milk. Of 970 samples of sugar analyzed all were found to be genuine. The Acts are working successfully wherever they are put in force. They are not enforced in the rural districts and the smaller boroughs.

The work of food inspection in the city of Paris has continued throughout the past year, the analyses having been conducted under the efficient direction of M. Ch. Girard, at the Municipal Laboratory of Paris. The inspection takes cognizance also of wall-papers, toys, cooking utensils, illuminating oils, etc.

The monthly reports received from the Laboratory state that the samples deposited by the public for analysis, and also those those seized by the inspectors, do not represent the average quality of goods

<sup>2</sup> Royal Commission on Metropolitan Sewage Discharge. Second and Final Report. London, 1884.

<sup>3</sup> Dr. R. Angus Smith, the chief inspector under these Acts, died while his report was going through the press.

<sup>4</sup> It is much to be regretted that certain works in Massachusetts are still conducting their operations in an offensive manner with scarcely the slightest attempt to prevent nuisance to the neighborhood.

sold in the markets of Paris, since such samples are usually of a suspicious nature.

The public are invited to deposit samples for gratuitous analysis with the commissariats of police, milk-samples to be brought between the hours of 11 and 3.

As a specimen of the work accomplished by this excellent system, the following summary of the work of the months of January and November, 1884, are here presented, the latter being the last monthly report received.<sup>5</sup>

Establishments and markets visited: January, 1884, 3,267; November, 1884, 1,305.

Destructions of articles of food, including fruit, meat, fish, and poultry, syrups, confectionery, mushrooms, tomatoes, vinegar, and pickles: January, 1884, 129; November, 1884, 180.

Character of Samples.	January.		November.		Classification of other samples.
	Total.	Good Quality.	Total.	Good Quality.	
Wines.	653	84	544	126	Bad quality, bitter, acid, musty, etc. Bad taste. Plastered to extent of two grains per litre. Addition of water. Artificial coloring matter. Salicylic acid, alum etc.
Vinegar.	25	9	16	10	Addition of water. Addition of lead. Substitution of white-wine vinegar.
Beer.	4	2	4	4	By addition of salicylic acid.
Cider.	5	2	8	5	Addition of water. Addition of coloring matter.
Alcohols & Liqueurs.	16	2	15	8	Use of alcohol having a bad taste. Use of salicylic acid.
Syrups.	8	2	14	3	Addition of glucose. Addition of coloring matter. Addition of salicylic acid.
Waters.	19	7	47	9	Not potable, in consequence of presence of mineral salts and organic matter.
Milk.	113	209	358	254	Addition of water. Substitution of cream.
Butter.	34	25	20	19	Addition of foreign fats.
Eggs.	6	4	11	8	Addition of foreign oils.
Flour.	16	15	15	14	Damaged.
Bread and pastry.	1	1	11	9	Made of flour of a poor quality.
Confectionery.	9	3	2	1	Prohibited coloring matters.
Honey and sweetmeats.					
Coffee and tea.	10	9	11	11	Foreign matters.
Pepper and spices.	3	1	15	10	
Toys.	8	0	1	0	Prohibited coloring matter.
Colored paper.	18	4	7	0	Prohibited coloring matter.
Cooking utensils.	20	9	15	9	Presence of lead.
Drugs.	13	11	2	2	Below the pharmacopœia standard.
Perfumery.	1	1	5	4	Presence of prohibited substances.
Hygienic articles.	11	6	15	12	Inflammable below the required temperature of 35 degrees C.

#### DISINFECTANTS.

A committee of the American Public Health Association authorized to report upon the subject of "disinfectants" have defined them as *agents capable of destroying the infective power of infectious material.*

Dr. Robinet, in the first chapter of the report as published,<sup>6</sup> gives the following summary of con-

<sup>5</sup> *Reçu des opérations des Laboratoires Municipaux de Chimie, de Médecine, de Pharmacie, de Janvier, 24, 1885.*

clusions as to the efficiency of haloid elements, chlorine, bromine, and iodine.

(1) Chlorine is an efficient disinfectant when present in the proportion of 1 part in 100; provided the air and the objects to be disinfected are in a moist state and the exposure continues for upward of one hour.

(2) Chlorine, when used in sufficient concentration to act as a trustworthy disinfectant, injures colored fabrics and wearing apparel.

(3) Bromine is an efficient disinfectant in the proportion of 1 part in 500; provided the air be in a moist state, and the exposure continues for upward of three hours.

(4) Iodine in solution is an efficient disinfectant in the proportion of 1 part in 500; the exposure continuing for two hours.

(5) The use of chlorine, and in a greater degree of bromine, requires considerable experience in management; when carelessly handled they may cause inconvenient or even dangerous symptoms in persons using them; for these reasons they are not suitable for popular use as disinfectants.

In the second chapter of the report,<sup>7</sup> Dr. Sternberg details the process employed in determining the comparative efficiency of commercial disinfectants.

The material employed as a test is "broken-down" beef-tea, in which the *bacillus subtilis* is invariably present, and in abundance. To this stock solution a culture of *bacillus anthracis* is also added on account of its noted power of resistance.

The time employed for experiment in each case is two hours. The amount of material employed is made equal to that of the disinfecting agent. The temperature of solutions is kept at 36° to 38° C. (96.8° to 100.4° F.).

The following table gives the results of experiments made. In four instances a failure occurred in the proportion of fifty per cent.; that is, when the undiluted solution was added to an equal quantity of the test-material:—

Name on Label.	Per cent. in which active.	Per cent. in which failed.
Little's Soluble Phenyle . . . . .	2	1
Labarraque's solution (liquor sodæ chlorinatæ U. S. P.) . . . . .	7	5
Liquor Zinci Chloridi (Squibb's) . . . . .	10	7
Feuchtwanger's Disinfectant . . . . .	10	8
Labarraque's solution (Frère, Paris) . . . . .	15	10
Phenol Solique . . . . .	15	10
Platt's Chlorides . . . . .	20	15
Glaudin Disinfectant . . . . .	25	15
Williamson's Sanitary Fluid . . . . .	25	20
Bromo-Chloratum . . . . .	25	20
Blackman Disinfectant . . . . .	30	20
Squibb's Solution, impure carbolic acid . . . . .	50	50
Burchard's Disinfectant . . . . .	50	50
Phenol Solique (Paris) . . . . .	50	50
Listerine . . . . .	50	50

The relative value of the agents as here given does not establish their comparative practical value as disinfectants. Questions of cost, physical properties, etc., come into the account.

Dr. Sternberg attributes a high disinfecting power to the liquor sodæ chlorinatæ (Labarraque's) and thinks it worthy of more attention than it has yet

<sup>7</sup> Medical News, February 7, 1885.

received. Samples obtained at different places vary considerably in strength.

In a supplementary report Dr. Duggan confirms the experiments of Dr. Sternberg as to the value of the liq. sodæ chlorinate and also of the hypochlorites in general, which possess the advantage of not forming a coating of insoluble albuminoid matter around solid or semi-solid masses and thus protecting them from further action. On the contrary, in moderately strong solution, they oxidize and disintegrate these materials. They are, at the same time, destroyed themselves in the reaction, so that we are rid of the germs, organic matter, and disinfectant, all at the same time.

Dr. J. B. Russell, of Glasgow, in an article which many would deem heretical at the present stage of knowledge as to disinfection, makes the following pertinent statement: "Perfect disinfection means killing the contagium before getting rid of its material substance. To take a shovelful of smallpox crusts and throw them into the ashpit, or to shake the débris from the flannels of a scarlatina convalescent over the window-sill, are not processes of disinfection. In a sense you disinfect the room which has been swept and the flannel which has been shaken, but you start the contagia in a fresh career of mischief." Dr. Russell advises burning for the former and thorough washing with soap and water for the latter, and states his belief that the municipal disinfecting apparatus of the future will be a large washing and cleansing establishment.\*

Prof. F. DeChamont expressed a similar opinion with reference to cholera: "There is but one true disinfectant, namely, fire. The majority of so-called disinfectants are simply deodorants. A system of drains properly flushed and protected would obviate the necessity of disinfectants. Unfortunately, the use of disinfectants is often only an excuse for uncleanness and insanitation. The only way of resisting cholera is to render the soil on which it is propagated perfectly barren."<sup>9</sup>

On the other hand, the wholesale use of disinfectants at the London Sewage outfalls at Crossness and Barking Creek is notable. Twenty-two tons of chloride of lime were daily discharged into the Thames with the sewage until recently, when the Metropolitan Board of Works determined to substitute permanganate of potash for the chloride of lime. The price of the permanganate rose to £140 per ton, upon which the Board erected works near the outfalls for its manufacture, which they professed to be able to do at £25 or £30 per ton.<sup>10</sup>

\*"On disinfection," by J. B. Russell, M.D., medical officer of health for Glasgow, Glasgow Medical Journal, December, 1884.

<sup>9</sup>Local Government Chronicle, August 2, 1884, London, p. 616.

<sup>10</sup>Local Government Chronicle, August 2, 1884, London, p. 614.

—Dr. Buchanan was again found guilty by a jury, at Philadelphia last week, of issuing bogus medical diplomas. A woman named Russell, who was tried at the same time with him, was acquitted on the criminal charge. She testified that, although she displayed a sign as a doctor, she had graduated from no medical school, and that the M.D. following her name meant "Money Down."

## Reports of Societies.

### PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M.D., SECRETARY.

MARCH 10, 1885. The President, Dr. F. W. DRAVER, in the chair.

Dr. S. G. WEBBER read an abstract of a paper on

#### SYPHILIS OF THE NERVOUS SYSTEM.

which is to appear in the coming volume of the Boston City Hospital Report. The following are some of the conclusions that he has reached:—

There is no pathognomonic symptom of syphilis of the nervous system; the diagnosis must be made by grouping the manifestations and viewing them and their history as a whole. Among the more frequent peculiarities is irregularity of the phenomena and their ephemeral nature, disappearing to come again.

Headache is the most common and the earliest symptom of syphilis of the central nervous system, and gives timely warning that the subsequent dangers may be avoided. Its characteristics are severity, with remissions or intermissions. The pain is persistent, or returns again and again. It is often, but by no means always, most severe in the latter part of the day or night. It may be limited or general, unilateral or bilateral. Nausea and dizziness are generally absent.

The ocular nerves are more frequently paralyzed than the other cranial nerves, and in general, paralysis is preceded by headache or trifacial neuralgia.

Hemiplegia is less likely to be sudden than to occur gradually, to be intermittent, to be preceded by headache, and to be accompanied by numbness of the same parts.

Syphilis of the spinal cord is less common than cerebral syphilis. Its prognosis is much less favorable, and it also has no pathognomonic symptom. Perhaps many of the cases of locomotor ataxia reported cured, were really cases of syphilitic myelitis. Syphilitic neuritis of peripheral nerves is not common, and is not easily recognized as such.

The time at which nervous symptoms appear after the primary sore varies in Dr. Webber's cases from two and a half months to twenty-five years; the majority coming, as is reported by other observers, within three years.

The reader hesitated to say much of prognosis. If headache exists alone, or if the symptoms are variable and intermittent, the prospect is fair. If there be organic change, recovery is doubtful, although the disease may be arrested. Some cases must be treated, at least intermittently, for many years, even after symptoms have disappeared. Slight cases may be treated with fifteen or twenty grains of iodide of potassium three times daily, continued many weeks after apparent recovery. In serious cases temporizing is dangerous, and iodide of potassium and mercury should be given in sufficient doses. Of the iodide, from seventy to two hundred and twenty-five grains have been given in the cases reported. Larger doses have been given by the reader, but without benefit and without harm. In some cases small doses have been badly borne,

but on increasing the dose the unpleasant symptoms have disappeared.

DR. F. B. GREENOUGH said that he had seen many cases of early nervous syphilis, some of them within a year from the time of infection. The case mentioned by Dr. Webber as having been sent to the hospital by him, had hemiplegia, when coming under his care, five months after the primary sore. He has seen him since, and he seems well. The speaker had seen an earlier case than that, in which a chancre appeared January 13, 1883, an eruption on the sixth of April, and right-sided hemiplegia on the twenty-fourth of May, about four months. This patient took iodide of potassium, and in a week was apparently well. There has been no relapse.

In syphilis, it is important to give iodide of potassium if there is headache, and there is nothing more wonderful in medicine than the action of this drug in these cases. Its effect is as marked as that of the subcutaneous injection of morphia in pain. A few doses, used at once, may give entire relief to a patient, who, if untreated, would undoubtedly have grave lesions. The speaker agrees with Dr. Webber in combining mercury with iodide of potassium, and looks on the iodide as valuable for holding symptoms in check, while mercury cures the disease.

DR. G. H. LYMAN reported a case which he remarked was somewhat different from those of the reader. I. T., aged thirty-five. Primary sore in November, 1882. Consulted him October 25, 1884, with a heavily loaded tongue, sense of prostration, headache, extreme vertigo, and slight numbness in left side and over the hepatic region. After a few office visits, the serious character of the affection became manifest; uncontrollable, intense vomiting, vertigo, and gradual loss of power over bladder and whole right lower extremity appeared. Pupils dilated, but no disturbance of vision. No aphasia. Catheter needed twice daily, and nutritive enemata. Under thirty to forty grain doses of iodide and innunction to the thighs, he was in six weeks much improved, and by the middle of December able to walk out. In February he appeared in vigorous health, although still conscious of slight impairment of power in the leg. While apparently well, his reluctance to a continuance of the medicine renders a recurrence not improbable. Dr. Lyman remarked upon the statement of Dr. Webber as to the rarity of vertigo, adding that most authors considered this symptom as a common one.

DR. WEBBER said that vomiting and vertigo do not usually accompany syphilitic headache, unless other head symptoms are present. In that case they are common.

DR. LYMAN inquired as to the exact pathological lesion.

DR. GREENOUGH said that Fournier, in his work published in 1879, goes into that thoroughly. The lesions come under three heads; inflammation of the meninges, of the arteries, and of the brain substance, and later neoplasms. He said, also, that early nervous cases have been reported as tertiary, which is probably incorrect. Zeissl supposes that precisely as the iris becomes inflamed as a secondary symptom, so does the arachnoid or the pia mater, without the dura mater or external periosteum being

diseased, and that early cerebral symptoms are a result of such inflammation, and not of neoplasms.

DR. W. W. GANNETT said that, so far as he knows, there is but one recorded autopsy with early cerebral symptoms. That was of a patient with syphilis less than six months old, who died of intercurrent disease of the lung. The pia mater was inflamed, and was half a line thick. As the patients generally recover in this stage, we do not often know the pathology.

In older cases there are one or two varieties of gumma, either a growth from the dura mater or periosteum, not affecting the central nervous system, or growths of connective tissue from the pia mater, extending from the periphery, which is composed of young connective-tissue cells, while the parts away from the border are cheesy, or are dense, and of old connective-tissue cells. Gumma in the brain are rare. Other changes reported by Heubner are thickening of the intima or media, causing the lumen of the arteries to be greatly lessened. Whether these changes are recoverable or not we do not know.

DR. LYMAN further remarked that whatever the postmortem may show, the trophic circle is not to be disregarded. The deterioration of the blood is of itself a most important factor in the production of the symptoms.

#### CHOREA AS AN HYSTERO-NEUROSIS.

DR. G. H. LYMAN read the following paper:—

I have frequently had occasion in former years to report cases of hystero-neurosis, such as laryngeal spasm, vomiting, dyspepsia, neuralgia of neck and temples, and among others two striking instances,<sup>1</sup> in May, 1880, one simulating gastric ulcer, and the other acute rheumatism, in both of which relief was obtained within a few hours by applications to the cervix uteri, the reflex troubles having their real origin in acute endo-cervicitis. Cases of hystero-neurosis of a mild form are now so commonly recognized as to be hardly worthy of report, but the following had been so long under treatment without recognition, and the relief was so strikingly instantaneous, that it seems worthy of record.

JANE B., a tall, nervous brunette from Nova Scotia, forty-three years of age and unmarried, entered the City Hospital November 4, 1884. With the exception of a pleuritic attack, fifteen years before, had always been in good health until June, 1881, that is, three years and a half ago, when she was subjected to a severe fright by a violent cyclone passing over the place in which she lived. It appears that she was standing upon a chair for some purpose, when the house was suddenly lifted and shaken by the storm. She was not thrown down, but to save herself made violent muscular effort. Either immediately or very soon after (June 29, 1881), she was seized with chorea, and has not been free from it since. For the past year the spasmodic movements have become worse, especially so before the menstrual periods, until now she is in a state of constant *jetitation*. She has been under treatment by different physicians, and by some of them told that she was incurable. She complains of pains over the body and limbs, which are most severe in the

<sup>1</sup> Boston Medical and Surgical Journal, vol. cli, p. 440.

sides and lower abdomen. For two years the catamenia have been irregular, occasionally suppressed for several months, as from June to October of this year. No positive history could be obtained of any pelvic disturbance. Had never suffered from dysuria. Never pregnant. Last menstruation six days before entrance. The menstrual history, in connection with her account of the original accident, led me to suspect some possible displacement or other pelvic trouble, and before commencing any medical treatment she was placed in position for a vaginal examination. The hymen, although intact, was easily dilatable, and the uterus found to be completely retroverted. It was no sooner replaced, and a small pessary inserted, than the choreic movements ceased entirely. She was retained in hospital to observe the effect of the next menstrual flow, which came on painlessly and naturally twelve days later, lasting five days. She left for her home in the Provines, November 24th, apparently perfectly well. The case is noteworthy from the almost magical relief afforded by a simple procedure, after three and a half years of physical suffering and the mental despondency naturally resulting from uncertainty of any possible medical relief.

Dr. WEBBER said that cases relating to the reflex nervous system are puzzling. Chorea is especially a disease of childhood, and that the age in this case would have led him to suspect something more. With the diagnosis unmade he would have thought of cerebro-spinal sclerosis.

Dr. J. COLLINS WARREN referred to the possible effect of nervous shock in the case. He had lately seen a man with pain and convulsions, and who could not walk. The case was medico-legal and the experts all agreed that it was hysterical, and many of them thought that recovery would be slow. Dr. Warren had thought it might not be very long, and has since learned that after the payment of a sum of money, recovery had been rapid. The man's honesty was not doubted.

Dr. LYMAN thought his case hardly hysterical, as it was not like hysteria, which he supposes to be a disease of the cerebro-spinal system.

Dr. A. H. NICHOLS mentioned a case of chorea in an adult, beginning with gastric derangements, bad nutrition, and flatulence, lasting a few weeks, and ending fatally. Movements were so violent that the patient's bed was made on the floor. He supposed that there was disease of the central nervous system.

#### URETHRAL SOUNDS.

Dr. POST showed a set of straight steel sounds with removable handle, for use in the anterior urethra. They were contained in a case of a proper size to be carried in the pocket.

#### DEATH FROM HEMORRHAGE INTO THE PANCREAS.

Dr. J. P. REYNOLDS reported the clinical history of a case. A man of sixty-six; was in Worcester, on Friday, when he felt pain in the epigastrium. He was able to come to Boston, however, and attempts were made to move the bowels. His color was good, and on Saturday he expressed his intention of being at his business on the following day. At 10 P.M. Dr. Reynolds was called to him

suddenly, and found him sinking and pulseless, and soon after midnight he died. During life, various theories were discussed and felt to be unsatisfactory. At the autopsy, Dr. Gannett, hearing now the history with the termination, at once suggested hemorrhage into the pancreas, and such proved to be the fact.

Dr. W. W. GANNETT exhibited the specimen, it being one of hemorrhage into the pancreas. As has been usually observed in such cases, the fat-tissue throughout the body was very abundant.

Apart from the pancreas, the organs showed no abnormal appearances.

The pancreas was imbedded in a large amount of fat-tissue. The organ itself was increased about one half in size, and showed on section a dark, reddish-black surface, due to the presence of much extravasated blood, nearly uniformly distributed.

The consistency of the organ was slightly diminished. Beyond the limits of the pancreas no evidence of hemorrhage was observed.

The bloodvessels and pancreatic duct were free.

Dr. Gannett gave a *résumé* of Balser's work, who reported cases two years ago in *Virchow's Archiv*. He believes that the abundant fat-tissue, seen in such cases, causes a sufficient pressure upon the bloodvessels to cut off nutrition, and so allow of a necrosis of the inter-lobular fat tissue of the pancreas. Following the necrosis a hemorrhage occurs into the substance of the pancreas.

The cause of death in cases of hemorrhage into the pancreas is best explained on the supposition of pressure on the solar plexus.

Dr. REYNOLDS observed that these cases had only had a place in literature during four or five years.

Dr. FRANCIS MIXER said that all the cases do not die in this way, and spoke of one at the Massachusetts General Hospital that passed for obscure ascites. The skin was dark, although the patient was American and white.

The PRESIDENT said that it is particularly interesting, where we have the clinical history joined to the report of the autopsy. He has seen the bodies of some six or seven who have been found dead in bed; where there was no history, and although death was evidently due to natural causes, yet an autopsy was necessary. These persons have generally been intemperate, flabby, and fat. The amount of hemorrhage has been quite moderate, and that it has been sudden has probably been a factor in causing death. There has been no bleeding into the peritoneal cavity. The only case of which he has clinical notes is one observed by Dr. Bush. When called, the patient was lying on the floor of a saloon, painless but in great anxiety, and collapsed. He did not respond to stimulants, and died in a hack, on his way to the City Hospital, in thirty-five minutes. The explanation of the cause of death, as given by Dr. Gannett, is supported by the literature of the subject. In the absence of an autopsy, such cases have probably been at times reported as heart disease.

Dr. REYNOLDS said that in malignant disease there may be an equal pressure, but that it differs, as had been stated, in not being sudden.

Dr. NICHOLS, in support of the theory that the suddenness of the pressure is a factor in the death,

called attention to the different effects of cerebral hemorrhage as it is sudden or slow.

DR. WARREN spoke of possible changes in the vaso-motor system caused by pressure on the sympathetic, and said that a blow on the sympathetic (on the frog's belly) causes vaso-motor paralysis and engorgement, resulting in symptoms resembling those of shock.

### SUFFOLK DISTRICT MEDICAL SOCIETY.

SECTION FOR CLINICAL MEDICINE, PATHOLOGY, AND HYGIENE.

ALBERT S. BLODGETT, M.D., SECRETARY.

JANUARY 14, 1885. Meeting called to order at eight o'clock by DR. R. T. EDES, Chairman. The records of the last meeting were read and approved.

The first business of the meeting was the election of chairman for the ensuing year.

DR. ROBERT AMORY proposed the name of DR. R. T. EDES, the present chairman, for reelection; the motion was seconded by DR. J. AYER, and being put by the Secretary, was carried unanimously. DR. EDES, in accepting the office for a second term, thanked the section for this mark of their esteem.

The paper of the evening was by DR. B. O. KIMNEAR, entitled "Cholera, and its treatment by DR. JOHN CHAPMAN's method, with twelve cases."

The author began with an account of CLAUDE BERNARD's well-known experiments with section of the pneumogastric and galvanization of the peripheral extremity, showing the vaso-motor function of that nerve. The view that glands are supplied with trophic nerves from the spinal axis, as well as with vaso-motor nerves from the sympathetic, was advanced, and it was claimed that excessive glandular action was caused by hyperemia of the cerebro-spinal trophic centres.

The writer then went on to present the views of DR. JOHN CHAPMAN on the nature and treatment of cholera based on the theory that this disease is "due to a superabundance of blood in, and excessively preternatural activity of, both the spinal cord and sympathetic centres," the former causing the active phenomena, and the latter the passive or negative ones. The symptoms of cholera were then enumerated and classified into one or other of these two groups.

The latter group included the symptoms of the algid stage, they being due to vaso-motor hyperemia. DR. CHAPMAN, considering cholera as entirely of nervous origin, assigned as its causes solar heat, electricity, violent changes in temperature, lowness of site, prolonged marches, fear, and the effects of alcohol and opium on the nervous system. The non-contagious nature of the disease was then shown, and was held to be a proof that the cause was no toxic influence. The teachings of KOCH regarding the comma-bacillus were objected to, and it was claimed that no micro-organism was constant in, or peculiar to, this disease. This portion of the paper was founded largely on an article by DR. CHAPMAN in the *Westminster Review* for October, 1881.

A series of twelve cases was then reported which were treated by means of the spinal ice-bag at

l'Hôpital de la Charité, Paris, during the late epidemic, and of which only two proved fatal.

DR. ROBERT AMORY said that he had thus far never seen a case of cholera, but it seemed to him that a paper like the one of this meeting should not be allowed to pass without careful consideration and discussion. From many of the statements contained in the paper one is forced to believe that both DR. CHAPMAN and the reader are influenced by an hypothesis in regard to the causation of cholera which they endeavor to support by the theory of hyperemia or anemia of the cerebro-spinal or of the sympathetic nervous system. The electrical power of magnets, the varying conditions of the atmosphere, and other cosmic influences and agents are easily explainable without reference to any specific disease. Again, most of the cases reported differ from cholera generally in the fact that they came very late under treatment and at a time when ordinarily patients with this disease are either dead or convalescent.

According to all accounts thus far received in relation to the recent epidemic in Paris, the disease was developed only in a very mild form, and, doubtless, many cases of a simple diarrhoeal character were included in the number as cases of true cholera. It is also somewhat striking that in the cases reported by the reader but little is noted concerning food or medicines, or any of the ordinary adjuvants of medicinal treatment. It would, therefore, seem that the mode of treatment here advocated is in no sense as yet worthy of being ranked above the formerly advocated and more generally employed methods of external and internal treatment. No one would venture to say that the spinal and sympathetic centres may not be the seat of congestion in cholera, usually in the algid stage, but the mode of argument advanced in the paper is in no way conclusive, nor its deduction satisfactory on this point.

DR. AYER said: It has been my fortune to witness the two last epidemics of cholera that visited Boston. The fear and dread—not to say panic—which the scourge inspired are fresh in my memory. I treated many patients. The onset of the attacks was usually violent, and its progress to a fatal termination rapid—usually within twenty-four to forty-eight hours. The early symptoms were vomiting and cramps, succeeded by diarrhoea; then the algid stage, rice-water discharges, suspension of urine, collapse, and death. The patient retained his mental faculties, and could speak, but extremely hoarsely, to the last. After the vomiting subsided the evacuations were odorless and the sick-room cleanly.

We had no distinct theory of treatment, but combated symptoms as they arose. For vomiting I employed alkaline solutions, tincture of opium, brandy, and sinapisms. The diarrhoea was met by opiates and astringents, and enemata of starch and laudanum and astringents. Ice was given to allay thirst and nausea. From the cold stage, and almost from the beginning, hot applications, dry frictions, and hot stimulants were freely given.

The disease affected the filthy localities and was specially fatal in the intemperate. Ice was never used externally.

Dr. G. N. THOMPSON said: During the two last epidemics of cholera in Boston I was called to treat quite a number of patients, suffering from that disease.

I tried the various remedies and modes of treatment that were recommended, for some time without satisfactory results. I found from experience that the stomach rejected all liquids, whether medicinal or nutritious, in about every case.

The painful cramps, rice-water discharges, vomiting, thirst most intense, and great prostration were palpable and prominent symptoms and characterized the disease, as I witnessed it from day to day. There was an entire suspension of the usual secretions of the digestive organs, liver, etc. There was intense pain and great prostration from the cramps and the deranged functions of the system, and the question arose how could these various destructive conditions be met and overcome by the attending physician.

The stomach would not tolerate liquids of any kind in most cases.

In the first place it was important to restore the functions of the liver and digestive organs: to relieve the cramps and pains which accompanied them; to restore and maintain the tone and vigor of the system through the trying ordeal. I argued that remedies in such a form as the stomach would tolerate must be used. I found that pills were retained if no liquids of any kind were taken.

After some thought and reflection upon the subject, I concluded that hydrarg. submur., opium, and quinine were the most potent remedies we had to meet these desperate emergencies.

I therefore used pills of each of the foregoing ingredients of two grains, as often as from half an hour to an hour, alternately in rotation, varying the dose somewhat, making it larger or smaller to meet the varying symptoms. Usually within from five to ten hours the patient would be relieved and the functions of the system restored.

Of course it would require time to regain the former strength and vigor.

Other means, such as applications of warmth with friction by rubbing, were used in all cases to promote the comfort of the patient.

Two of the cases deserve brief mention:—

CASE I. A man, aged forty years, had previously been in good health; had a family; was taken in the afternoon with vomiting, great thirst, cramps with much pain, profuse rice-water discharges, great prostration, could retain no fluids in the stomach.

Ordered the remedies as above suggested. Told his wife to give him no liquids of any kind, and to give the pills as directed, if she wished her husband to live. This was said to enforce directions.

Called in the morning and found the patient relieved from all his grave symptoms. Two others had been taken with the disease during the night. One of them was in the last stages of the disease and soon breathed his last. The other recovered under treatment.

Time was lost in the night by sending for the priest instead of for the physician.

CASE II. A man about forty-five years old, usually enjoying good health, was attacked late in

the afternoon. The late Dr. Gould, an eminent member of the profession in the city, was called in attendance. He was with him till past midnight. A member of his family being unwell, he sent for me to take charge of the case. The symptoms were very grave. I immediately gave him the pills as I have stated in the previous case. He was relieved of his painful symptoms by morning and recovered.

In almost all cases of intemperate habits, the chances of saving the patient were very slight. As I saw the disease, it was very violent and rapid in its progress, and liable to prove fatal in from twenty-four to forty-eight hours in many cases.

In the twelve cases treated by Dr. John Chapman's method, in Paris, in the paper read by Dr. Kinnear, some of them were not brought to the hospital until two or three days after the disease had commenced. I feel confident, therefore, that the epidemic there was far less malignant and rapid in its progress than it was here, as early, prompt treatment of the disease, as it prevailed here, afforded nearly or quite the only chance of saving life.

Dr. R. M. HODGES stated that from a considerable experience in two epidemics of cholera which have appeared in this city he is convinced of the truth of the assertion made by Dr. Amory that the disease as it has prevailed in France during the last five months does not represent the average severity of cholera. At the times when the disease was present in Boston, Dr. Hodges was accustomed to a much more rapid progress of symptoms and a much earlier termination of the case, in the recovery or death of the patient, than is here indicated. The cases described in the paper certainly present a duration of disease quite inconsistent with any preconceived opinions of cholera, which has generally the characteristics of extreme rapidity of succession in symptoms and speedy collapse or the commencement of convalescence. During the prevalence of any epidemic disease there are, doubtless, large numbers of cases wrongly included among its victims from errors in diagnosis, by which some other form of illness is mistaken for the dreaded epidemic disorder. In the presence of actual cholera there are usually many cases of a similar but milder disease, which are called "*cholericine*." The feeling of anxiety during an epidemic also, no doubt, causes an appearance of increased gravity in many cases which would not be considered to be of a serious nature at other times. Another important point in relation to the cases reported in the paper which forms the subject of discussion is the statement that one case of cholera was cured by the treatment described, but the patient soon afterward died from some other independent cause. A large number of cases of cholera yield to the immediate treatment, but succumb later to the secondary fever, which is a recognized feature in the convalescence of cholera. An ardent follower of any special mode of treatment may be deceived by the enthusiasm with which he is inspired, and the stronger conviction of an enthusiast is liable to lead to a more positive judgment than the facts warrant. It is not easy to know what to say in regard to cholera, because very little absolute knowledge exists upon this disease. The recent investigations of renowned

scientific men, extending over several epidemics and culminating in the discovery of a coincident, if not a causative, bacillary organism, have not aided the therapeutics of this disease. Dr. Hodges stated that he enjoyed especial opportunities for studying the disease at two separate periods: first as resident officer in the cholera hospital established on Fort Hill in Boston during the epidemic of 1856, and again as physician to the same hospital during the last visitation of cholera in Boston. He could not say that during these epidemics anything material was learned in regard to the successful treatment of the disease.

The employment of intravenous saline injections is neither new nor recent. This method was advocated many years ago in India. It was employed in the treatment of cholera here during the periods above mentioned, but in only one instance was there apparent benefit from this procedure. This fortunate patient was retained for some time in the hospital as a therapeutical curiosity, but finally ran away. Within twenty-four hours he was brought back again sick, and in a few hours was dead from cholera.

Dr. BLODGETT spoke of the recent epidemic in Paris, of which he had gained some knowledge by personal experience. The disease was certainly there regarded as of very mild type, and the rate of mortality was exceptionally low. The patients were almost entirely from the lowest, most improvident, and dissipated classes; and were considered to be especially vulnerable to any unwholesome influence.

The same error in diagnosis by which cases resembling cholera to a greater or lesser degree were mistaken for it was also noticeable in this epidemic, in which cases of so-called "cholérine" were reported, as well as cases of undisputed cholera. All the more common methods of treatment were employed, but the subsidence and final disappearance of the disease is associated with the occurrence of lower temperature and especially with the advent of frost. So far as it is possible to judge, the knowledge of the disease or of its successful treatment has not been materially advanced by the opportunities for observation and research in clinical and pathological directions afforded by the limited epidemic just ended.

Dr. EDES said that there were too many steps between the application of ice to the back and the cessation of vomiting to enable us to speak accurately as to what goes on in the spinal cord and ganglia, and assume that these are the paths of influence. It has been pretty conclusively shown that cold to the head does not cool the blood in the brain, and the spinal cord or the sympathetic is even further from the surface.

The tendency to formulate attractive theories of treatment in very obscure diseases is always liable to lead to erroneous deductions, and all investigations of this character should be conducted with more freedom of judgment and absence of prejudice than an enthusiastic advocate of a new idea is liable to possess.

Adjourned at ten o'clock, P.M.

A two per cent. solution of hydrochlorate of cocaine has been used by Dr. Weiss, of Vienna, to control the pain from severe burns.

## MEETING OF THE MASSACHUSETTS MEDICO-LEGAL SOCIETY.<sup>1</sup>

W. H. TAYLOR, M.D., SECRETARY.

FEBRUARY 4, 1885. The meeting was called to order at 1.05 P.M. by President Presbrey, eighteen members being present. Records of the last meeting were read and accepted.

On recommendation of the Executive Committee, Medical Examiners E. G. Hoitt, M.D., of Marlborough, and Z. B. Adams, M.D., of Framingham, were unanimously elected to regular membership.

Medical Examiner Tower, for the committee to whom the proposed amendments to the State law of medical examiners were committed with plenary power, made a statement that the matter would soon come before a committee of the General Court for consideration and hearing.

*Voted*, on motion of Medical Examiner Draper, that the vote of October 3, 1883, appropriating a sum of money for purchase and circulation of periodicals treating of legal medicine, be rescinded.

Medical Examiner Taylor read a report of a case of infanticide.

Medical Examiner Hartwell reported a case of infanticide.

Medical Examiner Gleason referred to the evidence of suffocation afforded by the presence of subpleural and other ecchymoses.

Medical Examiner Snow reported a case of attempted infanticide, the child sustaining life through an exposure of at least two hours in a privy vault, at a temperature below freezing.

Medical Examiner Tower reported a case of infanticide, showing rupture of the cord by the weight and fall of the child.

Dr. S. W. Abbott reported a case of attempted infanticide, where a child was buried in a manure heap for five or six hours, and subsequently resuscitated.

Medical Examiner Hoitt reported a case, showing liability of rupture of the funis from the weight and fall of the child.

Medical Examiner Fish reported a case of rescue of a neonatus after exposure of two hours in a privy vault, with a temperature at freezing point.

Medical Examiner Winsor suggested that in certain cases the contents of privy vaults may be warmer than the surrounding air, by the admission of sink-water and other sewage at an elevated temperature.

Medical Examiner Presbrey exhibited a very skillfully made rope, the material being cotton sheeting used by a suicide to hang himself.

Peculiar cases of death by hanging were reported by Medical Examiners Hoitt, Presbrey, and Holmes.

*Voted*, on motion of Medical Examiner Draper, that a subject for discussion for the annual meeting in June be chosen, and that members be requested to submit their discussions and reports in writing, that they may be available for subsequent use.

*Voted*, on motion of Medical Examiner Draper, that the subject for discussion at the next meeting be Death by Drowning.

<sup>1</sup> At the rooms of the Boston Medical Library Association.

## THE NEW YORK ACADEMY OF MEDICINE.

STATED meeting, March 5, 1885.

## ELECTION OF HONORARY FELLOWS.

Resident Fellows Alfred C. Post, M.D., LL.D., and John T. Metcalfe, M.D., were elected Honorary Fellows.

Dr. Wm. C. Jarvis read a paper on

## THE ETIOLOGY AND TREATMENT OF NASAL CATARRH, WITH SPECIAL REFERENCE TO DEVIATED SEPTUM.

In every case of nasal catarrh, he said, the essential point was to discover and remove the cause, and deviated septum he believed to be a very important factor in the causation of this trouble.

*Character.* It might be either osseous, cartilaginous, osteo-cartilaginous, or hypertrophic. The deviation might be localized or involve the entire septum. Osseous deviation was very rarely seen alone, but it not infrequently associated with the cartilaginous; the cartilaginous being by far the most common of all. The factors in the causation of chronic nasal catarrh were: first, pressure-irritation; second, defective nasal drainage.

*Etiology.* Having enlarged upon these points, Dr. Jarvis stated that deviated septum was sometimes due to heredity, sometimes to traumatism, and was sometimes acquired. Malformation of the hard palate was frequently transmitted from one generation to another, and with this was very apt to be associated deviated septum. It was when there was an abrupt elevation along the line of the median raphe that this trouble was generally seen; and with a palate of this conformation the individual was almost positively certain to have chronic rhinitis. He dissented from the proposition, so often maintained, that nasal catarrh was transmitted through the agency of a diathesis. Early acquired catarrh, instead of being the result of scrofulosis or diluted syphilis, was frequently an indication of unusual cranial development; the nares being correspondingly contracted. Remarkable mental capacity was thus apt to be associated with chronic nasal catarrh. In speaking of traumatism as a cause of deviated septum, he said that he had yet to see the first professional sparrer or prize-fighter who was not the subject of catarrh in consequence of deviation resulting from injury to the nose. Acquired deviated septum might be due to any prolonged intranasal pressure, such as came from hypertrophied tissue, the presence of polyp or other tumors, the constant insertion of the fingers into the nostrils, etc.

*Treatment.* No single method was applicable to all cases of deviated septum, the correction of which was essential to the cure of any case of chronic catarrh in which the condition existed. As a rule, he had found the most applicable and successful those procedures of his own to which he had referred in his paper before the American Laryngological Association in 1880. The instrument most useful in these cases was the *écraseur* with exceedingly fine piano-wire, which was always to be combined with his transfixion needles. The latter were from one to four inches in length, and

varied from straight to a marked curvature. When it was advisable to economize time, he employed his fenestrated cartilage-forceps and beaked scissors, which were of such a shape as to facilitate both operating and dressing. As bone blunted the trim edges of these instruments, when osseous tissue was to be removed, it was better to employ the *rougeur* forceps. When the deflection of the septum was extreme, there was great danger of its perforation by the operator, and under these circumstances the stellated punch was advisable. The cutting was the simplest part of the operation; the chief difficulty being in the proper approximation and adjustment of the raw surfaces.

*Relief of pain during operation.* The use of the *écraseur*, as a rule, was not attended with much pain, but he had found cocaine of great service in relieving the suffering of the patient, and was in the habit of using Foucard's ten per cent. solution. If the sensitiveness was extreme, however, there was nothing so good as the local use of rhigolene with the spray, which completely abolished all possibility of pain. The only objection to it was that it was liable to explode by the vapors coming in contact with the light used in the operation: and to obviate this he had devised an electric light, enclosed in a glass bulb, which he now exhibited. This was maintained by a Foster battery, which, he said, was a combined battery and accumulator. The great advantage of this apparatus was the long-continued current, and Mr. Foster, its inventor, claimed that it was necessary to refill it only once a year. Having recapitulated the prominent points of the paper, Dr. Jarvis concluded by showing his rhinometer, or nose-measurer.

Dr. Bosworth, in opening the discussion, said that he thought it was about time to drop the use of the word catarrh, which simply meant a discharge. As commonly employed it covered the whole area of nasal diseases, while it was in reality merely one of the results of various pathological conditions. In his paper in the *American Journal of Medical Science* for January, 1876, Dr. Harrison Allen had called attention to the importance of pressure-irritation; but his views had not been received with favor. Every one, he thought, had now plenty of instances of two mucous surfaces coming into contact with each other without giving rise to any truth, and he did not believe that pressure-irritation was of any weight whatever until quite late in the disease. As to defective nasal drainage, the nasal fluid was as benign and non-irritating as one could well imagine.

The paper of Dr. Jarvis, it seemed to him, therefore, did not get down to the ultimate source of trouble. It was in its atmospheric features that deviated septum assumed importance, and it was on account of the effect produced by it on the air in the nasal-passages that in nine cases out of ten deviated septum there was chronic nasal catarrh. The local effect of cocaine on swollen mucous membrane enabled us to make much more satisfactory examinations of the nasal cavities than was possible without its use, and the result of his observations was to establish the point that a primary factor in the etiology of catarrh, resulting from deviated septum, was an interference with the

normal respiratory function in the nose; the rarefaction of the air in the nasal-passages leading to dilatation of the neighboring venous sinuses. As regards hereditary elevation of the palatine arch, he believed this was due to *mollities ossium*, in which there was certainly a strumous element. The indication in the treatment was to remove the obstruction causing nasal stenosis, and, of course, a great variety of instruments and methods might be employed for this purpose. For the removal of some Dr. Bosworth preferred a very fine saw. In performing these operations he was in the habit of using cocaine as a local anæsthetic, and almost invariably with complete success in abolishing pain. On account of the expense of the drug he employed only the two per cent. solution, but he claimed that when this was applied to the parts for twelve or fifteen minutes before the operation it was just as effective as stronger preparations.

DR. S. O. VANDERPOEL, JR., said that some time since he had been struck by an article by Dr. Roberts, of Philadelphia, published in the *Boston Medical and Surgical Journal*, in which he described an operation for deviated septum which consisted of the division of the septum with a bistoury and the subsequent retention of the parts by means of a pin. He had resolved to try it himself, and had now employed it in five cases. In four the success was good, but in the fifth, a small child, the pin was inadvertently pulled out by the attendant. In one of the cases the nostril was so occluded that he found it necessary to employ Adams's forceps to break up the septum before resorting to the pin. The pin, he thought, possessed a great advantage in the fact that when it was used it was not necessary to keep any large foreign body in the nares, such as the nasal splint usually employed.

DR. DELAVAN said that he felt compelled to take issue with the author of the paper on some points. He believed that deflection of the septum was, as a rule, due to a deviation of the osseous structure, and many skulls which he had examined showed an extreme degree of deflection of the septum. There were other changes also involved, such as enlargement of the turbinated bone on the side of the nose where the cavity was the wider; and he had observed that patients with deviated septum often breathed better through the narrower nostril than through the wider one. The bony structures being thus involved, it was not enough, he thought, to remove merely the soft tissue; it was also necessary to take away a portion of bone. It was impossible to replace a deviated septum when there was an enlarged turbinated bone on the narrow side.

DR. JAMES, in closing the discussion, said that he quite agreed with Dr. Bosworth that the name *entarrh* was objectionable; but, as he himself had said some time ago, he thought it well to employ it on account of its commonly accepted use. In his paper, however, instead of always speaking of chronic nasal *entarrh*, he had alluded to hypertrophic rhinitis as a frequent condition. As to the fact of pressure-irritation resulting from prolonged contact of the parts, he was fully convinced of its existence and importance, not only from pathological researches but from the physiological action of the

turbinated bone which he had repeatedly observed in the living subject. He believed with Dr. Bosworth that normal mucus was non-irritating; but thought that thickened mucus of an increased specific gravity would invariably cause irritation by toppling into the larynx and closing up the nostrils. He acknowledged that the osseous turbinated enlargement, referred to by Dr. Delavan, did occasionally occur; but believed it was the rare exception, not the rule, and he had personally seen only two instances of it.

DR. GEORGE G. HOPKINS, of Brooklyn, read a paper on a case of

#### FIBROMA OF THE BREAST, OCCURRING AT SEVEN AND ELEVEN YEARS,

which we shall publish in full in the next issue of the JOURNAL.

#### CHICAGO MEDICAL SOCIETY.

LISTON H. MONTGOMERY, M.D., SECRETARY.

STATED meeting, February 16, 1885. DR. D. A. K. STEELE, President, in the chair.

#### MALIGNANT DISEASE OF THE THYROID GLAND.

DR. C. E. WEBSTER read a report of a case of this rare form of disease. The patient was a woman about sixty years of age. Her general health was quite good. The enlargement in the neck was first noticed about one year before the first consultation. It commenced in one lobe of the thyroid, and extended to the adjacent glands and tissues of the neck. Rubbing with liniments appeared to relieve this swelling, but it never entirely disappeared, and at the time he first saw the patient the gland had begun again to enlarge. Swallowing was difficult. The voice was husky, although respiration was not impeded. The thyroid gland, larynx, trachea, and neighboring cervical glands formed an irregular doughy mass. In the diagnosis of this case there were two possibilities to be considered: tertiary syphilis and cancer of the thyroid. The history of progression of the disease from an enlargement of the thyroid, and the fact that such an enlargement of this gland in people past middle life is almost invariably malignant, rendered the diagnosis easy.

A short course of specific treatment and an observation of the steady progress of the disease confirmed the early diagnosis. The patient passed on to a gradual exacerbation of her difficulty, and died recently of exhaustion.

The microscopic appearance of this growth is sometimes peculiar, hardly differing from that of a benign tumor of the same organ, so that oftentimes in these cases a positive diagnosis is difficult from a microscopic examination alone. The reader then recited an instance in the service of the Massachusetts General Hospital where such a doubtful tumor proved itself to be malignant by its recurrence after excision.

At the time of first consultation the disease in his case had progressed to such a stage that it would have been impossible to perform an operation successfully, as the deep tissues of the neck, including the œsophagus, were involved in the growth. The

time for an operation, therefore, would have been at the time the growth was first noticed. The size of the growth on the thyroid was as large as a hen's egg, or half of a hen's egg, and it extended in different directions, so that the tissue felt like a doughy mass, although the submaxillary glands were not involved in it.

#### TENIA SOLIUM IN A CHILD TWO YEARS OF AGE.

Dr. C. G. DAVIS read a report of a case of tenia solium occurring in a child two years old, and exhibited about four inches of the worm, including the head.

He was first called to see the child December 10th last, when it had not entirely recovered from an attack of entero-colitis, which it suffered from throughout the summer and autumn. The child was given a number of simple remedies, with raw beef. This treatment seemed to act properly. In a little while portions of tenia began to appear in the discharges. The child was then given half a teaspoonful of the French preparation pelletierine, followed in an hour with twenty drops of tincture of jalap and a table-spoonful of castor oil. This was followed by the expulsion of three or four yards of the worm, but the head was missing. The child was then carefully nursed, and its general health looked after, when segments of the worm again appeared in the evacuations. A double dose of the quantity of pelletierine, tincture of jalap, and castor oil, as above stated, was then administered, when several (seven or eight) more feet of the worm were dislodged, including the head.

Dr. DOERING stated that he had treated three children having tenia, one of whom was nine years old, another four years of age, and a baby who was but six months old. The last case had been fed on raw beef whilst it was sick with cholera infantum. He was surprised to hear of Dr. Davis's success with the remedies he had used, given in such small quantities, as he himself had practised the same method of treatment, and with larger doses of pelletierine, with but partial success only.

#### HYGROMA LINGUE.

Dr. JOSEF ZEISLER reported a congenital case of this rare disease. The patient, about nine years old, has been afflicted with it since her birth. The child is well nourished, but her complexion is pale and her face is asymmetrical to a considerable degree. The right half of her face is much more developed in its muscular and osseous formation than the opposite side. No swollen submaxillary or cervical glands are present. Her tongue was described as having the following appearance: It is much thickened; the surface appears to consist of small vesicles or cysts, varying in size from that of a pinhead to a pea, lying by the side of each other in the form of mosaic pieces of work, or in a tessellated shape. These cysts seem to contain a colloid mass, and this condition affects the entire visible portion of the tongue, so that no intact mucous membrane can be seen. Over the middle of the tongue there extends a kind of cockscorn, or carunculated excrescence. The same appearance is found on the mucous membrane of the right cheek, near the angle of the mouth. In handling or touching the tongue the surface imparts a sensation as if

it consisted of oil-globules or of boiled sago. The movements of the organ, as well as speech, are not impeded, nor is the sense of taste in the least impaired. There are no spontaneous pains proceeding from it, and pain arises only when strong compression is made upon her tongue, or, as the child says, when acid substances are taken. Relatives of the child report that its tongue was formerly much larger, although it sometimes now appears to become oedematous and then grow smaller again. Her parents and her five brothers and sisters have always enjoyed good health.

The speaker regards this disease from a pathological standpoint as a colloid degeneration of the mucous membrane of the tongue, but he could not classify it clinically, having never seen a similar case previously. A microscopical examination was not permitted to be made of any of the cysts or their contents. Regarding treatment, all that was suggested as a remedy was galvanopuncture, which the parents also objected to having done. It is probable that the child will be presented before the Society at a future meeting.

Dr. E. ANDREWS, Dr. C. T. PARKES, Dr. J. N. HYDE, and several other well-known physicians had seen this case, but could add nothing further of interest to it, nor to the treatment.

Dr. DOERING had seen this case two years ago. The tongue then presented a "sago-pudding" appearance, and he presumed it still retained the same features; he also stated that only two cases thus far have been reported in literature.

Exhibition of the "Koch's Comma-bacillus of Asiatic Cholera," by Dr. L. L. McARTHUR, after which the Society adjourned.

### Recent Literature.

*Practical Anatomy: a Manual of Dissections.* By CHRISTOPHER HEATH, F.R.C.S. Sixth edition. Revised by RICKMAN J. GODLEE, F.R.C.S. Philadelphia: P. Blakiston, Son & Co. 1885.

When a work has reached its sixth edition, its character may be supposed to be pretty well established and unless decidedly new features have been introduced it calls for no extended notice. The present edition is very nearly identical with the one before it. There are the same colored plates from Macleise and but few changes among the woodcuts or in the text. We believe that we have already expressed our opinion that minute anatomy should have no place in a work of this kind. There is evidently not space for it to be thoroughly treated and we see no reason why it should be treated at all. If any kind of microscopic work forms a part of practical anatomy it is that which requires little more than a simple lens, enough to make out details that just escape the naked eye. The arrangement of cells is as foreign to the dissecting-room as a discussion of the atom. As the work is said to have been revised by Mr. Godlee, we must own that we are surprised to find that the lesser curvature is in the upper border of the stomach and that no attention has been paid to Professor His's studies on the shape of the large abdominal viscera, though they are accepted in the last edition of Quain's Anatomy.

# Medical and Surgical Journal.

THURSDAY, MARCH 19, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by CUPPLES, UPHAM & CO., Boston. Price, 15 cents a number; \$5.00 a year, including postage, to subscribers in the United States and Canada. Foreign subscribers are charged the postage in addition.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

283 WASHINGTON STREET, BOSTON, MASS.

## GASTROTOMY WITH DILATATION OF THE ORIFICES OF THE STOMACH.

AN operation which bids fair to prove a valuable addition to the series of brilliant achievements of recent abdominal surgery has been devised, performed, and described by Professor Loreta, of the University of Bologna. The plan consists essentially of a gastrotomy with mechanical dilatation of obstructed orifices, the fingers being used for stricture of the pylorus and a steel dilator being employed when the obstruction is at the cardia. The author's original pamphlets contained a description of the operation and an account of the earlier cases, and were reproduced in English in some journals at that time. His subsequent experience, as shown by notes hitherto unpublished, is given by Mr. Holmes in an article in the *British Medical Journal* (February 21, 1885). The first operation, digital dilatation of the pylorus, has now, in the two years since its first performance, been done by him, in all six times. The success, according to Mr. Holmes's paper, has been perfect, although a sketch by Dr. Robert T. Harris in the *Medical News*, some two years ago, records two fatal cases among the earliest operations — an important discrepancy, it must be admitted.

The pyloric operation is designed solely for cases of non-malignant stricture when sufficient mechanical obstruction exists to cause marked dilatation of the stomach, and is intended as a substitute for pylorotomy. As will at once be seen, this involves a nice point of diagnosis in excluding, on the one hand, dilatation from chronic gastric catarrh, and, on the other, various organic maladies. Where the dilatation is idiopathic, therapeutic measures, notably irrigation of the stomach, are indicated. In cases of malignant disease, pylorotomy offers the only chance of relief. But where the dilatation is due merely to mechanical obstruction, this milder operation of digital dilatation affords a good promise of success. That the latter condition is more common than is generally believed is shown by the fact that, since these investigations were begun, the

revelations of the autopsy have, in a number of cases, shown that what was at first taken for cancer was merely a sclerosed and contracting cicatrix resulting from old inflammatory conditions.

For this diagnosis, so important to be made, Professor Loreta relies largely upon the chemical and microscopical examination of the vomitus or of the washings from the stomach. These matters, on being allowed to stand in a glass vessel, divide into three strata, the upper consisting of mucus containing gas-bubbles, the middle of limpid serum, and the lowest of "a granular humor, grayish in color, or mixed with fine detritus of food imperfectly digested." If the dilatation be of mechanical origin, this lowest layer consists of chyme, well elaborated; there is little mucus and plenty of serous fluid. The reaction is acid and the microscope gives negative results. The patient will express himself as being quite relieved from his discomfort by the act of vomiting, after which he is at once hungry. There is an absence of fetid eructations, colicky pains, and alternating diarrhea and constipation. On the other hand, when the dilatation is idiopathic there are the symptoms of indigestion, nauseous eructations, and pain, which, as well as the loathing for food, is not relieved by vomiting. The extracts from the stomach are neutral or alkaline and, on separating into layers, have a bad odor; but little chyme is found; the middle or serous layer is turbid with particles of undigested food. There is much ill-smelling mucus in the upper stratum. Chemically, the albuminoid substances are found unchanged, and microscopically the evidences of incomplete digestion are perceived. These signs of failure in the chymifactive process are naturally not confined to the idiopathic forms of dilatation, but are also to be seen in those secondary forms which depend upon general infection of the system and accompany cachectic conditions.

The method of the operation may be sufficiently understood from the description of the plan followed in the first case.

The stomach having been washed out with an alkaline solution, the incision was made on the right of the median line for fifteen centimetres, the upper and inner end being about four centimetres below the xiphoid cartilage, the lower and outer end three centimetres from the cartilage of the ninth rib. The hemorrhage was stopped before the peritoneum was opened. Some adhesions of the thickened omentum to the parietal peritoneum and the anterior surface of the stomach having been separated, the stomach was set free, and was then drawn out of the wound as far as necessary. The pylorus was felt to be thickened, and of a fibrous hardness. The coats of the stomach were then lifted up into a transverse fold, and a cut made through them with strong scissors midway between the two curvatures, about three centimetres from the pylorus; and it was found necessary to enlarge

this cut to six centimetres, on account of the contraction and hypertrophy of the muscular coat. The hæmorrhage, which was free, was repressed by means of hæmostatic forceps of a T-shape. Then the right forefinger was introduced, and the pylorus examined. It was found very hard and prominent, and its orifice appeared closed. No force that could be safely used succeeded in dilating it, till the left index-finger was also introduced and employed to steady the pylorus. When this was done, the end of the right forefinger was gradually squeezed through the aperture. Then the finger was used to hook down the pylorus toward the abdominal wound, a manœuvre which enabled the operator to get the left index also through the pylorus. But it was still exceedingly difficult to effect any separation of one finger from the other, so great was the resistance, not only of the sphincter itself, but also of the coats of the stomach and duodenum. The attempt at dilatation threw the muscular fibres into spasmodic action, which quite overcame all the force that could be exerted. Three such attempts were made in vain, but then the pylorus began slowly to yield to the force employed, which was very considerable. At length a sensation was experienced "showing that the tissue was so far distended that it could not obey the dilating finger further without being torn." The fingers were now kept apart for a short time, and the spectators noted that one finger was about eight centimetres (more than three inches) distant from the other. The dilatation was effected with difficulty by separating the fingers, and a feeling was imparted to the operator of a yielding of the tissues which if carried further would cause laceration.

The wound in the stomach was then sewn up, the viscus returned into position, and the abdominal wound united. "The whole proceeding lasted thirty-three minutes. The patient felt no inconvenience on waking, except a little burning sensation in the region of the wound, and thirst, which was relieved by giving him small pieces of ice. In the evening he was allowed the yolk of an egg beaten up with wine, of which a teaspoonful was given every half-hour. The temperature remained all day at 37° Cent. (=98.6° Fahr.); pulse 72; respirations 26. He felt comfortable, and had a natural appetite. He was fed for the next few days on liquids, and on the fifth day was allowed to eat some chicken. On the eighth day the abdominal wound was found united by the first intention, and some of the sutures were removed. From this time a meat-diet was allowed. Sixteen days after the operation (September 30th) he got up for a couple of hours, and began rapidly to recover strength and gain flesh. On September 12th (two days before operation) he was weak, lean, wretched-looking, and weighed 112 pounds. On October 30th he weighed over 134 pounds, and his face was cheerful and composed.

The first operation for dilatation of the cardia was performed in October, 1883, for a stricture resulting from the cicatrization following the injection of caustic alkali. The stricture was situated at the level of the fourth dorsal vertebra. Attempts at dilatation by bougies had been unsuccessful, and deglutition had gradually become more difficult, till it was no longer possible. An incision was made from the xiphoid cartilage downward and somewhat to the left, five inches in length. On drawing out the stomach and making the incision, the orifice of the œsophagus was reached with some little difficulty, and a dilator (similar in form to that used by Dupuytren for lithotomy) introduced. This instrument had blades of twenty-four cm. in length, and capable of separation to five cm. It was run up and down the œsophagus four times, the wound was then sewed up, and the stomach returned to the abdomen. Six hours after the operation the patient swallowed soup and egg without difficulty. Recovery was complete in eighteen days, interrupted only by an attack of dyspnoea, with increased bronchial secretion, lasting a few days and thought to be possibly due to mechanical irritation of the sympathetic or vagus nerves. It is noteworthy that a similar attack occurred in another case. This operation has now been done six times, four times by Professor Loreta, and in all the cases, according to Mr. Holmes, with perfect success. It is offered as a substitute for the always unsatisfactory gastrostomy.

In reading the account of these certainly remarkable cases, one is led to query whether there is not danger, as with other strictures, of recontraction following, there being no means of maintaining the dilatation by subsequent use of instruments. On this point the author says that he relies on his experience of digital dilatation of cicatricial strictures of the anus, in which a permanent cure always results if the operation be performed under anaesthesia, very slowly, and the force gradually exercised until the sphincter is dilated to the extreme, by forcing the two fingers either to each tuber ischii or to the pubes and coccyx. After such slow dilatation, the sphincter will recover its functions and, Professor Loreta believes, will not recontract—a more sanguine view, perhaps, than most surgeons would be willing to take; while, after too rapid dilatation, its fibres will probably be torn or contused here and there, and the injured part will inflame, causing fresh cicatrization, as is the case also in urethral stricture after mechanical dilatation.

In the operation upon the œsophagus where the advantage gained by the sense of touch is wanting, and where there is consequently more risk of laceration of the muscular coats, there seems still more cause for apprehension that the stricture may be reproduced. It should be said, however, that in none of the cases operated upon, in some of which seven months have elapsed, has any return of the symptoms appeared.

One of the difficulties in the way of the success of this operation is likely to be found in the matter of diagnosis. Despite the reliance placed by the author on the physical characters of the vomitus, nothing less than the most careful and minute study of all other attending circumstances will sometimes avail to solve the problem. One cannot fail to admire the ingenuity displayed in diagnosing some of the cases, notably the first operated upon, where the presence of a tumor of the pylorus was discovered by palpation and its non-malignant character asserted. Some of the most striking achievements of recent surgery have been gained only by the skillful coöperation of medicine, and have demonstrated the essential unity and mutual interdependence of the sister sciences.

#### STATE REGULATION OF MEDICAL PRACTICE.

THE Legislatures of quite a number of States are to be called on during their present sessions to consider various proposals for regulating the practice of medicine. The latest draft we have received of a bill for this purpose comes from Texas. New York, Ohio, Massachusetts, and Kansas are also among the States who begin to awake to the necessity of doing something in this direction. Each State which adopts and enforces efficient legislation puts a pressure upon other States to do the same as a protection against the dislodged hordes of quacks and nostrum venders. So that the movement is one likely to gain in velocity in a constantly increasing ratio, especially as the people begin to find out that the discouragement of medical ignorance and the encouragement of medical education is in their own interest and not in that of "the doctors."

In a State like Massachusetts, for instance, a member of the Massachusetts Medical Society already has all the privileges and advantages which the State can or will confer, and those privileges and advantages may be summed up in the one word—recognition. Whether or not the State shall see fit to put a penalty upon practising medicine without State recognition really concerns him very little, except in so far as he may be interested in the welfare of his fellow-citizens, whom it should concern very much.

The bill presented to the Texas Legislature is very similar to that recommended to the Committee on Public Health of the Massachusetts Legislature by a Committee of the Massachusetts Medical Society. It provides for a uniform mode of examination by a single board of examiners, and for official registration; all expense to be covered by the charges.

Another form of bill, suggested in Massachusetts, provided that each medical body chartered by the

State should examine its own candidates and recommend them to the State for recognition. At present there is a homoeopathic and there is an eclectic Medical Society, with State charters, in addition to the Massachusetts Medical Society; and there is no reason, if pathies and dogmas and specialisms are chartered at all, why there should not be a dozen or twenty other chartered societies.

For our own part, we are inclined to think it a mistake to multiply boards and petty offices if it can be avoided. A State which has a well-organized Board of Health has ready to hand the necessary machinery for putting into operation the provisions of a bill whose main features are a uniform standard of requirements and official registration.

The regulation of medical practice in Illinois and West Virginia, as carried out through their respective Boards of Health, has produced very satisfactory results, and this seems to be practically the most efficient and successful method of administering such laws as have yet been tried in this country. If a State has not a suitably organized Board of Health, if such work is to be done, it were well to provide one.

#### THE CASE OF GENERAL GRANT.

WE have no special information to give of the character of the disease of the distinguished ex-President or of its progress toward the inevitable conclusion of epithelioma so situated. The daily bulletins of the non-medical press contain all the available information, and that seems to us far too much; the extreme publicity given to the minutest details of the daily physical and mental changes can hardly be acceptable to the distinguished sufferer himself or his friends, and do not commend themselves on the score of good taste. Nor is it necessary to say anything in a periodical addressed to the medical public of the characteristics of his malady.

Few physicians have escaped the sad duty of watching the steady decline of some victim of malignant disease of some portion of the mouth or pharynx. Few cases make a greater demand upon the sympathy of the medical attendant; and who, that has watched the course of a single case of the kind, can fail to feel an admiration for the quiet endurance of the sufferer? All the obstinacy and the patience, the bull-dog tenacity, which is attributed to him as a General finds now ample scope. Undoubtedly the local anæsthesia to be obtained from cocaine may greatly mitigate his sufferings, but not the utmost resources of modern surgery can entirely dispel them or rob the disease of its characteristics.

The spectacle of patient endurance of unavoidable suffering, of calmness in the face of steadily approaching death, always awakens the admiration of a physician, and we can say without reserve that at this time, when the whole nation feels a reawaken-

ing of regard for its victorious General and its former President, he has no deeper sympathy from any than from those who can best appreciate the nature of his sufferings—the physicians. This sympathy is not lessened by a brave acceptance of inevitable laws as based upon the best experience and knowledge of the day, and a rejection of the false hopes—so often yielded to by men of weaker fibre—which are offered by quackery and empiricism. It was long ago discovered that “he who ruleth himself is better than he who taketh a city.” A man, who, amidst all the chances and changes of a very varied and active life, and when at last a shining mark for the slings and arrows of a most outrageous fortune, is still able to calmly meet and dominate the situation, has those qualities which entitle him to command others, the essentials of a great man.

The unfortunate fall which General Grant met with more than a year ago was a far more serious matter than at first thought probable. In view of the character of the fall, the seat and nature of the injury, and the very slow and imperfect recovery,—the patient still walking with a cane,—the medical mind—even in the absence of an easily appreciable shortening and eversion—reverts to the possibilities of an impacted fracture of the neck of the thigh-bone.

That injury, whatever its precise nature, enforced an irksome inactivity, thereby causing a lowered general vitality, with which the mental depression attendant upon the subsequent financial disappointments had to be encountered. When one adds to all these disasters the epithelial cancer, it forms a total of misfortunes before which the stoutest heart might quail.

#### MEDICAL NOTES.

—The relative numbers engaged in some of the professional callings in the United States, as shown by the census returns of 1870 and 1880, were as follows:—

The number of clergymen in 1880 was 61,698 against 43,894 in 1870; the number of lawyers was about the same—in 1880, 61,147; 1870, 40,736; the number of physicians in 1880 was 86,000; in 1870, 62,000; the number of teachers and scientific men in 1880 was 228,000; in 1860, 110,000; the number of dentists in 1880 was 12,311; in 1870, 7,839. These figures are to be interpreted in the light of an increase in the total population during the decade of thirty per cent.

—The *Medical Times* notes the remarkable reimplantation of a tooth, originally described by Dr. Bestion in the *Gazette des Hôpitaux* of January 17th, a case which is probably unique as regards the length of time in which a tooth remained without replacement, after being forced out of its socket. A sailor while engaged in securing a vessel placed the rope in his mouth in order to have a hand free. A comrade inadvertently tightening this rope forced

out upon the deck the lower left median incisor tooth. After some searching the tooth was found, but it was not until seventeen hours after the accident that the sailor related his adventure to Dr. Bestion, producing his tooth in a state of absolute dryness. After soaking it in water for a few minutes and then drying it, Dr. Bestion replaced it, the operation causing pain and some hæmorrhage. The tooth keeping in pretty straight, no bandage was applied, the only precaution taken being to substitute for the biscuit, soft bread, which, for the early days, was moistened with water or wine. At the date of the report, that is to say, three months after its replacement, the tooth was found to be quite solidly in place, the only change observable being a diminution of the brilliancy of the surface. Dr. Bestion cannot find any case on record in which a tooth had been successfully replaced after a later period than four hours had elapsed. This is related by Magitot as occurring in a child ten years of age. This author also relates several examples of this time having elapsed in his operations in which the tooth has been intentionally drawn and replaced after the diseased parts had been excised. He also relates the case of a laborious removal of a wisdom tooth, that necessitated the preliminary extraction of the second molar, which was reimplanted about four hours after the operation.

—The physicians of General Grant are being flooded with applications from cranks, quacks, astrologers, and soothsayers, who offer to cure the distinguished patient in various periods of time.

#### NEW YORK.

—The commencement exercises of Bellevue Hospital Medical College were held at the new Metropolitan Opera House Monday evening, March 9th, when the degree of M.D. was conferred upon 131 graduates. The successful candidates for appointment in the Bellevue Hospital, named in the order of merit, were: Sollace Mitchell, of Florida; Lewis M. Silver, of New York; Thomas J. Charlton, Jr., of Georgia, and George G. Larcombe, of Georgia. The Hon. William Dorsheimer made some remarks in reference to the recent gift of \$50,000 by Mr. Andrew Carnegie, for the erection of a pathological laboratory, and Mr. Carnegie himself, who was received with much enthusiasm, delivered the address to the graduating class. The college announces that in the spring session the opening of the Carnegie Laboratory, fully equipped with scientific apparatus, will take place. The laboratories will be open to any one who desires to make original investigations, or who may wish to pursue any special line of experimental work under the direction of those officially connected with the college; and it is expected that culture-apparatus imported from Germany will arrive in time for the cultivation of bacteria during

the present season. The teaching in the laboratories will be under the direction of Professors Janeway and Dennis, assisted by three instructors.

—The forty-fourth annual commencement of the Medical Department of the University of the City of New York took place at the Academy of Music Tuesday evening, March 10th. The graduates numbered 178, and the degrees were conferred by the Rev. John Hall, D.D., chancellor of the University *ad interim*, who also delivered the address to the class. Four hospital appointments and other prizes were awarded, and the valedictory was given by Frederick Osborn Lord.

—The commencement exercises of the American Veterinary College were held at Chickering Hall on Wednesday evening, March 4th, when in a class of thirty-one the highest honors were taken by Haru Taka Yokura, a native of Japan. The degrees were conferred by Mr. Samuel Marsh, president of the Board of Trustees, and Prof. Charles H. Doremus awarded the prizes.

#### PHILADELPHIA.

—Dr. Formad, of the University of Pennsylvania, has also recently delivered two public lectures at the Franklin Institute, on the germ theory of disease, which were well illustrated and largely attended.

—Harrison Allen, M.D., has resigned from the chair of Physiology in the Faculty of the University of Pennsylvania.

—Ellerslie Wallace, M.D., Emeritus Professor of Obstetrics in the Jefferson Medical College, died at his home in Philadelphia, on March 9th, of facial erysipelas.

—Dr. Osler, of Philadelphia, has recently delivered the Gulstonian lectures, three in number, at the Royal College of Physicians, in London, on "Fleerative endocarditis." They are highly spoken of in the English medical journals.

### Correspondence.

#### CHOLERA—"A DI ALTERAM PARTEM."

*Mr. Editor.*—The *London Lancet* of February 28th last gives a somewhat lengthy notice of the Official Report of Surgeon-General J. M. Cunningham, head of the Indian Medical Service and Government Sanitary Commissioner, on completing his public career of thirty-three years in India.

It will be interesting, in connection with the discussions on the subject which have appeared lately in this journal, to note the results of the "long experience and exceptional opportunities" of one whom the *Lancet* says is "well known to be a most capable public servant, and has had unsurpassed opportunities of forming an opinion of the matter with which he is dealing"; especially interesting also as confirming, in no small degree, the less sensational but more common-sense views occasionally advanced in this journal but generally ignored by inexperienced theorists.

The article in the *Lancet* is too long to copy in full, but a few abbreviated quotations will be useful, and

may suffice to induce a reference to it as well as to the work itself when it shall have become accessible.

As regards the endemic area of the disease, which is known to have existed in India at least four hundred years ago, Dr. Cunningham points out that "the districts which suffer most are by no means those which are in most direct or constant communication with the endemic area, nor is the reverse true that those districts which escape are comparatively isolated and removed from intercourse with the endemic area." Again, "the great drainage channels, into which much of the choleraic matter must eventually find its way, run in the reverse direction of the epidemic. Railways have now placed the whole country within a few days of the endemic area, but the frequency of epidemics has by no means increased, nor is their movement more rapid, while their direction is wholly unaltered."

"Dr. Cunningham tells us," says the *Lancet*, "that all attempts to keep out cholera from places in India have signally failed, and so satisfied has the government become of the futility of quarantine, that it has been altogether prohibited. All experience in India, he says, goes to show that 'to impose quarantine or cordons in order to keep out cholera is a proceeding no more logical or effectual than it would be to post a line of sentries to stop the monsoon.' As regards troops and prisoners . . . removal has proved successful even when the parties moved have carried their sick to the new place, and have drawn their supplies, including their water-supply, from the affected place which they had left. . . . Nor need any fear be entertained that the removal of bodies of men, even when suffering from cholera, will prove a source of danger to the community at large, and especially to the community to whose neighborhood they have gone. Among the many moves made in this country there is no instance of this kind on record."

Regarding the visitation of cholera to Europe and America during the last fifty years, "in Dr. Cunningham's opinion the upshot of all the evidence goes to show that during the fifty years passed under review the places which are in the most direct and constant communication with India have suffered least; that since direct and constant communication was established between India and Europe, Europe has suffered from cholera invasions less frequently than it did before; and that in spite of railways the recent European epidemic traveled no faster than did that of 1832."

Dr. Cunningham considers "the system of medical inspection to be useful in itself but not to be depended on as a means of preventing cholera invasions. Ships coming from cholera-stricken places may be expected to have cholera sick on board; 'the sick have suffered because of the influence of the place from which they have come, and the best evidence of the groundlessness of the fear attaching to them is to be found in the fact that in nearly every instance they are isolated cases, and the rest of the ship's crew have not been attacked. There is great difference between the arrival of persons suffering from cholera and the arrival of the influence or causes which produce cholera.'"

Isolated cases occur in all countries every year, and are mis-named, he says, when not followed by an epidemic.

As to the duties of the state in connection with the prevention of the disease, Dr. Cunningham, according to the *Lancet*, says: "Each country should have its own sanitary administration, which should be occupied entirely with carrying out sanitary improvements within its own boundaries, and with collecting information to show where these are most wanted, and what results they have produced. If it is to be of any value, the whole practical action must be based on the great truth that the measures which will confer protection from cholera are measures directed, not against the freedom of the person, but against the insanitary

condition of the place in which he lives." To this the *Lancet* significantly adds: "Such measures will not only diminish cholera, but they will also diminish the many other diseases which, though less alarming, are by their constant drain on the population in reality much more destructive than cholera."

These statements and opinions sound very like what has occasionally appeared in the JOURNAL from less experienced observers. They, however, cannot be expected to be scientific enough for theorists in organisms, or sensational enough for those who place absolute reliance on official interference. Fashion is now with the sensationalist. An influential medical periodical recently averred: "If the present National Board of Health were clothed with adequate power it could prevent the introduction of foreign pestilences into our seaports. . . . The qualified health officer can intercept the cholera contagion." "Adequate" is good; "qualified" is good; by all means let us have such at once if possible; but do not let us lose our heads in unproved theories or impracticable schemes.

M. M. S. S.

## COCAINE FOR SLEEPLESSNESS.

PORTLAND, MAINE, March 12, 1885.

*Mr. Editor*,—An original application of a well-known property of cocaine may be worthy of a few lines in the columns of the JOURNAL.

A short time since I lost almost nightly for two weeks nearly all my sleep. At the end of that time

it seemed almost impossible to keep awake, and one night, when I found that I should be obliged to pass another wholly sleepless night, it happily occurred to me to try a hypodermic injection of cocaine. I used five minims of McKesson & Robbins's four per cent. solution—a good preparation, by the way—with the most pleasing results. I felt wide awake in a moment and was able to read understandingly a very abstruse book. This was about 9 p.m., and at 1.30 a.m. I took five minims more with the same good result. There were no disagreeable after-effects and with the exception of a slight sense of oppression after the second injection there were no effects either immediate or remote to remind me that I had taken any drug. The pulse, I think, was slowed somewhat, but of this I cannot feel sure because my duties as nurse necessitated frequent exercise on my part. I have repeated the experiment twice with the same result.

A small dose of morphia has the same stimulating effect upon me, but the congested state of the brain makes any sustained intellectual effort all but impossible. This congestive feeling cocaine will almost wholly remove.

Metcalf's fluid extract of coca I have found a useful tonic. As a spray its effect on singers' throats is something wonderful, and it is always useful. The wife of a medical confrere here relieved the pain of an ulcerated tooth with some of the extract after laudanum had failed. The surprise was of course great. The study is interesting but costly, too costly for thorough investigation.

Yours truly,

WALTER WOODMAN, M.D.

## REPORTED MORTALITY FOR THE WEEK ENDING MARCH 7, 1885.

Deaths reported 2,802; under five years of age 911; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, and diarrheal diseases) 383; lung diseases 561, consumption 391, diphtheria and croup 139, measles 41, scarlet fever 32, typhoid fever 32, diarrheal diseases 30, malarial fevers 24, erysipelas 24, whooping-cough 14, puerperal fever 14, cerebro-spinal meningitis 11. From typhoid fever, Philadelphia 11, Baltimore 5, Boston 4, New York and Lowell three each, District of Columbia and Worcester two each, St. Louis and Milwaukee one each. From diarrheal diseases, New York 14, Brooklyn and Boston 4 each, St. Louis three, Providence two, District of Columbia, Milwaukee, and Nashville one each. From malarial fevers, New York 9, New Orleans 6, Brooklyn 5, St. Louis 3, District of Columbia one. From erysipelas, Brooklyn 5, New York 4, Philadelphia, Boston, and New Orleans two each, St. Louis and Milwaukee one each. From puerperal fever, Brooklyn 4, District of Columbia 3, New York and Milwaukee two each, Philadelphia, Baltimore, and Buffalo one each. From whooping-cough, Brooklyn 4, New York and Philadelphia three each, Buffalo, District of Columbia, and Milwaukee one each. From cerebro-spinal meningitis, Milwaukee 3, New York and Boston two each.

Cases reported in Boston: scarlet fever 41, measles 26, diphtheria 24, and typhoid fever 8.

Three cases of small-pox were reported in St. Louis.

In 108 cities and towns in Massachusetts, with an estimated population of 1,477,813 (estimated population of the State 1,355,104), the total death-rate for the week was 17.75 against 20.76 and 18.25 for the preceding two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,906,446, for the week ending February 21st the death-rate was 20.5. Deaths reported 3,508; infants under one year of age 804; deaths in London 1,497; acute diseases of the respiratory organs (London) 343; whooping-cough 117, measles 19, scarlet fever 45, fever 36, diarrheal diseases 35, small-pox (London) 32, Liverpool and Manchester one each 34. The death-rates ranged from 11.8 in Brighton to 37.9 in Sunderland; Birkenhead 15.7; Birmingham 21.0; Blackburn 23.2; Hull 17.4; Leeds 19.4; Leicester 20.3; Liverpool 22.7; London 19.1; Manchester 23.8; Nottingham 20.0; Sheffield 20.3. In Edinburgh 19.4; Glasgow 28.4; Dublin 30.4.

In the Swiss towns for the week ending February 21st there were 36 deaths from consumption, lung diseases 34, diphtheria and croup 11, diarrheal diseases 10, small-pox 5, whooping-cough 3, erysipelas 3, typhoid fever 3, puerperal fever 2, measles 2. The death-rates were: at Geneva 23.3; Zurich 11.3; Basle 21.2; Bern 33.8.

The meteorological record for the week ending March 7th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Date. March, 1885.	Barom- eter.	Thermometer.				Relative Humidity.		Direction of Wind.	Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MARCH 7, 1885, TO MARCH 13, 1885.

Army Medical Board to meet in New York City, April 6, 1885, detail for Board: Lieut.-Col. JOS. B. BROWN, surgeon; Major ANTHONY HIGER, surgeon; Major JOHN H. JANEWAY, surgeon.

Surgeon HIGER to be relieved from duty in Department of the East, and Surgeon JANEWAY to perform duties on the Board in addition to his present duties. S. O. 56, A. G. O., March 11, 1885.

BROWN, H. B., major and surgeon. Granted leave of absence for one month, with permission to apply for two months' extension. S. O. 18, Department of the East, March 6, 1885.

TAYLOR, BLAIR D., captain and assistant surgeon. Leave of absence extended two months. S. O. 51, A. G. O., March 9, 1885.

PORTER, J. Y., captain and assistant surgeon. Sick leave of absence further extended fourteen days on account of sickness. S. O. 51, A. G. O., March 5, 1885.

#### APPOINTMENTS.

MASSACHUSETTS GENERAL HOSPITAL. Dr. Charles P. Strong has been elected Physician to Out-Patients at the Massachusetts General Hospital in place of Dr. D. H. Hayden, resigned.

Dr. Herman F. Aikema has been elected Physician to Out-Patients at the Massachusetts General Hospital in place of Dr. F. Gordon Merrill, resigned.

ADAMS NERVE ASYLUM. Dr. Frank W. Page having resigned, Dr. Samuel G. Webber has been elected Superintendent.

of the Adams Nerve Asylum. Dr. Webber will retain office hours in Boston, as heretofore, for consultation and office practice.

#### SOCIETY NOTICE.

SUFFOLK DISTRICT MEDICAL SOCIETY.—There will be a special meeting of the Society at 19 Boylston Place, on Saturday, March 21, 1885, at 8 P. M., to provide for the appointment of delegates to the meeting of the American Medical Association, and to receive the report of the committee to nominate officers for the ensuing year.

CHARLES M. GREEN, Secretary.

## GRADUAL REPOSITION OF AN INVERTED UTERUS BY A NEW CONTRIVANCE.]

BY JAMES R. CHADWICK, M.D.

On June 1, 1884, I admitted a patient to my private hospital with an inverted uterus. She was a sparse woman of frail appearance who had been delivered of her first child by forceps after a tedious labor in September, 1883. There had been excessive hemorrhage in childbed, and the uterus was said "to have come down" at that time. There was, however, no indication of any untoward result of the confinement except general feebleness, which kept her in bed for two or three months. Twice, at intervals of several months, she had had severe flooding, by which she had been considerably but not dangerously reduced. She brought a letter from Dr. John L. Sullivan stating that she had recently come under his care and that he had tried unsuccessfully for two hours to reduce the inverted uterus, with the patient under ether. The uterus was of normal size and inverted nearly up to the external os which could be felt firmly encircling the inverted cervix.

A few days later the patient was etherized by Dr. F. H. Lombard, when I made an attempt, with the assistance of Dr. G. H. Lyman and Dr. C. M. Green, to reduce the inversion with various instruments for applying upward pressure upon the fundus, moulding the organ with my finger in the intervals, but not being able, owing to the smallness of the vagina and rigidity of the perineum, to introduce my whole hand into the vagina. When the organ was drawn partially out of the vulva I could push a finger in the rectum into the cavity made on the peritoneal side by the inverted organ, and even tried to dilate the rigid conical constriction in that way (Court's method), but was deterred from exerting sufficient force by the fear of tearing the peritoneum. After two hours of effort without apparent gain the congested appearance of the uterine body and the feebleness of the patient led me to abstain. A considerable rent in the perineum was closed by two sutures. No bad symptoms supervened, but it was two weeks before the tenderness of the fundus and the cicatrization of the perineum justified further interference.

I determined that my next attempt should be by the gradual process. Accordingly, I next sought to exert steady, moderate pressure upon the fundus in the direction of the vaginal axis by inserting into the vagina two, and, finally, three, superimposed inflated rubber rings (doughnut pessaries) of three successive sizes, the smallest being at the top and partially encircling the fundus, the largest resting upon the perineum; this worked well when first adjusted, but became speedily disarranged and inefficient. I had satisfied myself, however, that the largest ring was well retained by the perineum, and made a good basis for the erection of a superstructure with which to push up the fundus. The ring was reinserted, and through its central aperture was passed a spherical-rubber pessary collapsed; the latter was then inflated by means of the rubber-

tube attachment, which, passing through the opening in the ring, hung out of the vagina. The patient experienced some slight pain during the following night, requiring for its relief but an eighth of a grain of morphine. The pain ceased suddenly about thirty hours after the instruments were arranged, and the next morning I found that reposition had been accomplished. The os was still very patulous and remained so for several days, but what was more important, the uterus was in complete retroflexion. It was replaced by means of the repositor, and the cervix kept well back by means of a wool tampon; the organ, notwithstanding, retroflexed again, owing to the extreme laxity of its tissues. This displacement recurred again and again in spite of any vaginal pessary that I could fit, until I prevented the flexion by means of my light intra-uterine stem in addition to an Albert H. Smith pessary, wearing which she returned to her home in good health on the fourteenth day after reposition. This probable consequence of reposition should be borne in mind, especially as no writer on the subject, so far as I know, gives any data of the condition subsequent to reposition.

This is the only case of chronic inversion of the uterus that has come under my care, but I cannot readily blot out of memory the spectacle to which I was summoned at four o'clock one morning about two years ago. A practitioner of this city, of considerable obstetric experience, roused me from my slumbers to aid him in the reduction of an acute inversion under the following circumstances as related by him. He had delivered a woman at four o'clock in the previous afternoon without instruments and the placenta had soon after been expelled spontaneously. He had left her comfortable and free from hemorrhage. At 12 p.m. he was summoned to her bedside because of flooding and found a large tumor protruding from her vulva which he correctly diagnosed to be the inverted uterus. This he vainly attempted to reduce, but finally, by wrapping clothes about it, he checked the hemorrhage and came for me. We did not reach the house until nearly 5 a.m., when the woman was found to be dead. An immense tumor—the inverted uterus and vagina—lay between her thighs reaching almost to her knees.

In considering the treatment of chronic inversion we are met by the rival claims of the methods by rapid and by gradual reposition. The former was practised by the late Dr. James P. White, in a large number of cases, with signal success, but it is not devoid of danger, and necessitates long-continued anesthesia of the patient and exhausting efforts on the part of the operator. It is, moreover, as shown in my case, not uniformly followed by success in the practice of other less skilled practitioners.

The gradual method has generally proved effectual and is devoid of danger. As to the precise means of applying the pressure operators have differed, and probably different cases call for different procedures. On the whole, Dr. Wing's method is the most efficient, and suited to the largest number of cases, especially to those patients in whom the perineum has been ruptured or is lax. Where the perineum, as in my case, is so firm as to give adequate support and the vagina is narrow, it seems

<sup>1</sup> Read before the Obstetrical Society of Boston, January 10, 1885.

to me that my method offers the advantage of obviating the necessity of external straps and a rod, with the constrained position which they entail. My contrivance applied the force in the direction of the long axis of the vagina without wasting it upon the walls of the vagina, as does an ordinary rubber bag, such as has been used by others.

Should reposition prove impossible by either the rapid or the gradual systems of treatment, recourse may be had to the more dangerous but certain method of opening the abdominal cavity and dilating the constriction from within as recommended by Dr. T. G. Thomas, or better still, by the practice recently carried out successfully in one case by Dr. B. B. Browne, of Baltimore, of cutting through the fundus and dilating the cervix through this incision. Amputation of the inverted organ, which has been practised with fair results, may likewise be resorted to.

#### REPORT OF A CASE OF RECURRENT FIBROMA OF THE BREAST AT SEVEN AND ELEVEN YEARS OF AGE.<sup>1</sup>

BY GEORGE G. HOPKINS, M.D., A.M., OF BROOKLYN, N. Y.

MINNIE G. C., aged eleven years. Born in Michigan. Good physique. Mother has uterine fibroma. Father died of acute nephritis in 1881, aged thirty-four years. Grandfather on father's side died of "valvular disease of the heart" at sixty-three years of age; grandmother on same side still living and healthy.

Mother's father died at seventy-two years of age of "liver and kidney disease," to quote from family; grandmother on the same side living and healthy. All natives of the United States.

Immediate family consists of one brother two years senior, one sister two years, and one sister four years junior, all healthy.

When Minnie was seven years old, Dr. B. F. Plows, of Hancock, Mich. (since deceased), removed from her right mamma a tumor about the size of a chestnut, which he pronounced to be "malignant." Its location was just to the outer side of the nipple, and on a plane parallel with it, situated in the substance of the gland, as is shown by the cicatrix. This gland at present shows no indication of disease, and except for the line of incision—which, unfortunately, is perpendicular instead of horizontal, as it should have been—is perfectly normal in all its relations.

The second growth, which was in the left breast, was first noticed in May, 1881, about six months after the removal of the first tumor; it was then quite small. It was first brought to my notice through correspondence in the spring of 1883, when it was little more than an inch in diameter. It then ceased to grow, and the mother postponed any operative measures, as the family physician advised non-interference, hoping that it might disappear. They could detect no increase in its size until June last, when it began to enlarge rapidly, and they decided to bring her on to me for operation.

I saw her the first week in September, and found a tumor occupying the substance of the gland, sev-

eral of the axillary glands being also involved in the disease. She presented a ruddy, healthy appearance, with no indication of impaired health; the catamenia had not yet appeared. An operation for the extirpation of the entire gland was recommended as soon as the weather would permit. In this decision Dr. J. C. Hutchinson, who saw her with me in consultation, concurred.

The operation was done on the sixth of October, Dr. Rogers administering the ether, and Dr. Hutchinson kindly assisting me. I removed the entire mammary gland, with four axillary glands, which were also diseased and enlarged; the nipple and areola were also excised with the tumor.

Antiseptic precautions were observed throughout the operation. There were no vessels of sufficient size divided to require ligation, hot water serving to

check all the hemorrhage. Wound cleansed with bichloride of mercury solution; flaps coaptated with antiseptic catgut sutures, several strands of catgut being inserted in an opening made at the most dependent portion of the axillary flap for drainage. A large pad, shaped like the side of a vest, was made to envelop the left side and shoulder, the material being crinoline; the filling was antiseptic sawdust, the pad held in position by numerous turns of crinoline bandages.

The dressings were left undisturbed until the ninth day. My intention had been to leave them at least two weeks. They were only removed at that early day as the patient complained of pressure. The entire dressing was removed at this time (the ninth day) and the wound was found to have healed in its entire length; several of the sutures had been dissolved, but there was no excoriation at any point, the only discharge being from the drainage-opening; this was devoid of odor and was principally serous. The remaining sutures were dissolved by the eleventh day, the drainage-opening closing on the sixteenth day.

There was very slight elevation of temperature, the highest point reached being 100° F., at nine p.m. on the day of the operation, and this was undoubtedly due to excessive irritability of the stomach from

<sup>1</sup>Read before the New York Academy of Medicine, March 5, 1885.

the ether; the pulse at the same time was 90, and about normal during subsequent period of healing.

The interest in this case lies in the fact of the early age at which the disease manifested itself, which is fairly to be regarded as seven years of age in this patient; as the first tumor was undoubtedly of the same histological nature as the second tumor.

In his exhaustive work on Tumors of the Mammary Gland, Professor S. W. Gross says of fibroid tumors: "They have been met with as early as the twelfth year." He also informs me that he does not know of its having been met with at so early an age before and pronounces it true fibroma.

The cut presents its structure beautifully. It is copied from a section under the microscope colored with carmine.

## REPORT ON MEDICAL CHEMISTRY.

BY WILLIAM B. HILLS, M.D.,

Assistant Professor of Chemistry, Medical Department of Harvard University.

### URINARY CHEMISTRY. — ELIMINATION OF PHOSPHORIC ACID IN THE URINE.

The elimination of phosphoric acid in the urine in insanity and epilepsy has been investigated by M. A. Maïret<sup>1</sup> and M. A. Lailler.<sup>2</sup> Maïret's conclusions are as follows: In mania the results differ according to the particular phase during which the investigations are made. In the stage of excitement there is an increase in the elimination of nitrogen and phosphoric acid. In the period of depression the nitrogen and alkaline phosphates are diminished, while the earthy phosphates are increased. There is a decrease of nitrogen and phosphates during a remission. In epilepsy there is an increased elimination of these substances during an attack. In melancholia the earthy phosphates are increased in amount, and the alkaline phosphates and nitrogen are diminished.

Lailler's results were obtained from many hundred analyses, made while resident officer in a large asylum, and are as follows: In acute delirium phosphoric acid and urea are eliminated in notable excess; in excitable mania the phosphoric acid is in slight excess, while the amount of urea is normal; and in simple insanity the urine has the normal composition. In acute or excitable lypemania the amount of urea eliminated is abnormally high, while that of phosphoric acid is abnormally low. In simple lypemania the composition of the urine is normal. In general paralysis the elimination of both phosphoric acid and urea is related to the general morbid condition of the patient. At or immediately after epileptic seizures the urine contains a high proportion of phosphoric acid and a low proportion of urea. If the seizures succeed one another rapidly, the proportion of both phosphoric acid and urea is increased; but in the interval between seizures the urine has the normal composition.

M. Maïret<sup>3</sup> has investigated the influence of muscular and intellectual exertion on the elimination of phosphoric acid with the following results: The elimination of phosphoric acid is connected with general nutrition, the elimination of both alkaline and earthy phosphates being greater, the greater the decomposition of albuminoids, or, in other words, the greater the elimination of nitrogen. The effect of muscular exertion on the elimination of phosphoric acid depends on the state of nutrition. Phosphoric acid is used up, and if the exertion is proportionally greater than the amount and quality of the food assimilated the elimination of nitrogen and alkaline phosphates in the urine is increased; but if the diet is rich and abundant, muscular exertion has no effect on the amount of phosphates eliminated in the urine.

The effect of intellectual exertion, like that of muscular exertion, is closely connected with the sufficiency or insufficiency of the diet of the individual. The general result is a diminution in the quantity of nitrogen and alkaline phosphates eliminated in the urine, the amount of diminution depending on the duration of the intellectual effort. When the diet is insufficient, relatively to the work done, an additional effect is produced, and the amount of earthy phosphates eliminated is increased. For one and the same diet, the more severe the intellectual effort, the greater is the increase in the elimination of earthy phosphates. With a purely vegetable diet the increase is particularly well marked. It follows from these results that phosphoric acid is intimately connected with the nutrition and activity of the brain, and that, when the brain works, it absorbs alkaline phosphates and gives up phosphates of the alkaline earths.

### EXCRETION OF UREA AND INORGANIC SALTS UNDER THE INFLUENCE OF AN ARTIFICIALLY INCREASED TEMPERATURE.

Experiments made to determine whether high temperatures caused by artificial means influence the excretion of urea in the same manner as fever have led to very contradictory results. C. F. A. Koch<sup>4</sup> has repeated some of these experiments, at the same time extending his observations to the excretion of the phosphates, sulphates, and chlorides. The results were mostly of a negative character. The urea was not increased in any experiment. The phosphates and chlorides show a slight decrease of only very short duration, while the sulphates are unaffected. As an increase of carbonic acid expired takes place at high temperatures, experiments were made to determine whether any direct relation exists between the amount of carbonic acid expired and the urea excreted. No such relation could be found.

### PEPTONURIA.

Dr. Grocco<sup>5</sup> has published the results of his investigations on 300 patients, of whose urine more than 700 analyses were made. Peptonuria is always to be considered as a morbid fact, and is altogether independent of albuminuria. Peptonuria is as much a symptom of local disease as of general disease,

<sup>1</sup> Medical Record, August 16, 1881, page 193.

<sup>2</sup> Journal of the Chemical Society of London, January, 1885, page 73, from Compt. rend. 39, page 522.

<sup>3</sup> Journal of the Chemical Society of London, December, 1881, pages 1392 and 1394, from Compt. rend. 39, pages 243 and 282.

<sup>4</sup> Journal of the Chemical Society of London, December, 1884, page 1394, from Zelt., f. Biol. 19, page 417.

<sup>5</sup> The London Medical Record, January 13, 1885, page 22.

infective or not. Among general peptogenic diseases are marsh-infection, typhoid fever, scurvy, purpura hæmorrhagica, septicæmia, and acute phosphorus-poisoning. The local morbid processes which give rise to peptonuria are almost exclusively of inflammatory character, and most often suppurative. Among local inflammatory processes acute and subacute nephritis, the first especially, must not be omitted. Not all inflammatory processes, even when suppurative, give rise to peptonuria. In those of chronic course especially, it is often absent. Very rarely in malignant new growths of rapid development there may be peptonuria. In local processes the hypothesis is probable that the peptones formed in the affected part pass into the blood, and from the blood into the urine. In general diseases the pathogenesis of peptones is unknown. Peptonuria cannot be regarded as a diagnostic symptom between simple exudation and purulent exudation. But it does help us to conclude with great probability in cases of local disease, in which, from the site of the disease and from its course, the diagnosis is uncertain, that an inflammation, probably suppurative, rather than any other morbid state, exists. Peptonuria is very frequently met with in the period of resolution of pneumonia, but is not constantly present then, and, moreover, may be found before resolution occurs, or in the course of gray hepatization. In pleurisy peptonuria has no practical value as a guide to treatment.

#### SYNTHESIS OF XANTHINE.

M. A. Gautier<sup>6</sup> has effected the synthesis of xanthine by heating, in sealed tubes, hydrocyanic acid mixed with water and acetic acid to a temperature of 140° to 150° C. The product is a mixture of xanthine and methyl-xanthine.

#### LEVULOSE IN DIABETIC URINE.

J. Seegen<sup>7</sup> reports a case of diabetes mellitus in which the urine contained levulose, a variety of sugar which has been observed in the urine in only a few cases.

#### TOXICOLOGY.

*Chlorate of Potassium.*—Dr. J. von Mering<sup>8</sup> has carried on, in Hoppe-Seyler's laboratory, an elaborate experimental investigation into the physiological, therapeutical, and toxicological actions of chlorate of potassium. He finds that the salt, under the influence of carbolic and probably of other acids, is decomposed in the system with the gradual liberation of chloric acid, which tends to reduce the alkalinity of the blood; and in this lies the key to the right understanding of the action of the chlorate. The author discriminates between acute and subacute poisoning by the chlorate. In acute cases, such, for instance, as result from the administration of one large dose of the salt, death results in the course of a few hours from decomposition of the blood, with symptoms of severe vomiting, profuse diarrhoea, intense dyspnoea, cyanosis, and profound cardiac depression. On section, there is found a chocolate-brown color of the blood, while

the organs generally, especially the kidneys, are relatively little altered in appearance. The blood contains the stored-up products of its decomposition (methæmoglobin, etc.). With a less acute form of poisoning death results, not simply from an accumulation of oxidation-products in the blood, but from an accumulation of these in the organs, especially the kidneys, leading to occlusion of the tubules, scanty urine, and anæmia. The following symptoms and appearances are observed: grayish-violet petechiæ, icterus, accumulation of hæmoglobin in the blood, changes in the red corpuscles, dyspnoea, and cardiac depression; gastro-intestinal disturbances, such as profuse diarrhoea and severe vomiting, the vomited matter being generally greenish black, and enlargement of the liver and spleen. Functional alterations in the kidneys, such as anuria, occur, the scanty, turbid urine having a reddish-brown or black color, and exhibiting the spectra of methæmoglobin and hæmatin, and being also highly albuminous. It also contains numerous detritus-masses of red blood-corpuscles, in the form of brown cylinders or brownish-yellow flakes. Uræmic complications, such as delirium, coma, severe vomiting, tonic and clonic convulsions, and rigidity of the limbs, are observed. The subjective phenomena are headache, anorexia, tenderness of the stomach on pressure, pains in the hepatic and lumbar regions, intense oppression of the chest, and a feeling of extreme weakness. Post-mortem examination reveals the characteristic chocolate hue of the blood and the presence of methæmoglobin in it; but sometimes these phenomena are absent, especially when the patient has long survived the administration of the poison, or when the necropsy has been delayed for several days. The spleen, liver, and kidneys are considerably enlarged, and filled with the accumulated brown products of destruction of the red blood-corpuscles. The greatest alteration is observed in the kidneys, in which both the straight and convoluted tubules are filled with brownish masses, partly cylindrical, partly irregular in shape. The osseous marrow is brown, and contains numerous decomposed blood-corpuscles. The gastric mucous membrane is swollen and ecchymosed.

While the majority of instances of poisoning by chlorate of potassium (cases in which icterus and scanty secretion of reddish-brown urine occur) terminate fatally, this has not been invariably the case. A chronic poisoning by the salt is incredible, and it has been observed that the prolonged ingestion of small doses has been followed by no injurious results; but the condition of the stomach, whether empty or full, and the degree of alkalinity of the blood, greatly influence the result. The use of the chlorate in febrile affections, where there is subnormal alkalinity of the blood, is to be avoided; and the author emphatically condemns, as especially dangerous to life, the internal use of the salt in large doses in the treatment of diphtheria. The author gives the following as the maximum safe doses, when the use of the salt is not contraindicated: for adults, thirty-grain doses, with a daily maximum of two drachms; for children, aged ten to fourteen years, one drachm daily; for children, aged one to ten years, thirty to forty-five grains daily; and for

<sup>6</sup> *Journal de Pharmacie et de Chimie*, August 4, 1884, page 101.

<sup>7</sup> *Centralblatt für die Medicinischen Wissenschaften*, 1884, No. 43, page 753.

<sup>8</sup> *The London Medical Record*, December 15, 1884, page 518.

infants, not more than fifteen grains daily, always given in divided doses.

## LEAD.

Ellenberger and Hofmeister<sup>9</sup> have studied the effects of small and repeated doses of lead salts on sheep. The salt of lead employed was the acetate, in doses of 0.5 to 3 grammes per day, gradually increasing from the smaller quantity. The symptoms observed were loss of appetite, apathy, disturbed rumination, muscular weakness, dry, dull wool, diminution of urine and urea, disappearance of hippuric acid, presence of albumen in the urine, and protruding bowel.

The quantity of lead extracted from the different organs varied considerably. Contrary to expectation, the kidneys proved to contain as much as the liver. After the kidneys and liver, the largest amount was found in the salivary glands, pancreas, bones, and nervous system, in the order named. The blood and muscular system contained but little lead, but the spleen contained a comparatively large quantity. The authors think the poison attacks the nervous system first, and then the muscular system. Excretion takes place by the kidneys, liver, pancreas, and saliva, according to the preparation of lead employed; it is perceptible in the urine in about forty hours.

## Hospital Practice and Clinical Memoranda.

CARNEY HURRELL.

SERVICE OF H. L. BURRELL, M.D.

### CASES OF PERINEAL ABSCESS DEPENDENT ON URETHRAL STRICTURE.

REPORTED BY E. D. HOOKER, M.D., HOUSE SURGEON.

CASE I. Joseph W., aged twenty-four: jumped from a window a year and a half ago and the right hip has troubled him some since. During the last eight months there have been symptoms of pus formation in and about pelvis. There is a sinus four inches long in right iliac region, parallel with Poupard's ligament and discharging from a small opening; also three fistulous openings in perineum: the first appeared five years ago as a boil which was poulticed and lanced: the remaining two a year later. Urine comes from the most anterior opening in drops, during micturition, but at no other time. History of gonorrhoea seven years ago. Meatus enlarged by Dr. M. H. Richardson, prepuce cut as far back as corona of glans penis, and the sinus above referred to freely laid open. A fortnight later commenced to complain of pain about the right hip and a collection of pus was thought to be present. No limitation of movement at hip-joint. An incision two inches long was made just below the right greater trochanter: a sinus six inches in depth discovered running toward iliac region. Examination per rectum revealed a swelling on right side, two inches from anus, having a crescentic

margin and an indistinct sense of fluctuation; aspirated, but no pus.

External urethrotomy advised as the patient was bed-ridden and anæmic, with fistulous openings in perineum, two sinuses in thigh and one in groin, all discharging pus and a stricture at seven and three-quarters inches, impassable even to fine capillary bougies.

Wheelhouse's operation performed. The patient was placed in lithotomy position and the grooved staff with blunt-hooked extremity introduced to the stricture, with the groove outward: this being held in position an incision was made through the tissues of the perineum, in the median line, down to the urethra which was opened on the groove of the staff, one quarter of an inch in front of the stricture. The edges of this were then drawn apart, the staff turned half round and withdrawn till its blunt-hooked end engaged in the upper angle of the wound in the urethra. A probe-pointed director was then introduced through the opening in the stricture, which was hidden by granulations, toward the bladder with its groove downward, on which a sharp-pointed tenotome was entered and the stricture thoroughly divided. After this the probe-foret was introduced into the bladder, by aid of the director, dilating the stricture and forming a passage into the bladder. A number ten English silver catheter was then introduced through the meatus, passed along this metallic floor into the bladder, secured in position and its external openings plugged; this plug to be removed every four hours. Wound dressed with iodoform, sublimate fossil-meal pad, and a T bandage. In the evening there was no necessity for changing the dressings. On the second day the wound was looking finely, healing by first intention. No dribbling of urine from wound or three fistulous openings in perineum. No marked elevation of temperature. Third day the catheter withdrawn; sound to be passed every third day. Wound completely united.

On sixth day all dressing of perineal wound discontinued. Conical steel sounds nineteen to twenty-one, French scale, passed readily into bladder. Sounds passed every third day, gradually substituting larger sizes till thirty French was reached, when discharge from wounds about hip was markedly less.

During the two following months is a history of diarrhoea, symptoms of amyloid liver, with urine containing albumen and waxy casts. Improved for a month, when he was discharged from hospital, at which time there was but very slight serous discharge from one of the openings about hip, and those of groin and perineum were closed.

CASE II. Michael K., aged thirty-seven: entered hospital with history of gonorrhoea and subsequent stricture. An area of redness and induration discovered extending from mid-point of perineum to two inches posterior to anus and to the tubercles of ischia on either side; half an inch to left of anus was an opening, discharging pus quite freely, through which a probe could be passed to the depth of three inches in a direction parallel to the urethra. Urine voided without difficulty. A stricture at four and one-half inches existed, admitting number seven English sound. By rectal examination prostate

<sup>9</sup> Journal of the Chemical Society of London, January, 1884, page 71, from Biol. Centr., 1884, page 335.

found not to be involved. Numerous free incisions were made in perinaem, evacuating a large amount of extremely offensive pus: syringed out with carbolic 1-40.

Dressing of sublimated fossil-meal pad. Second day general condition much improved. Perinaem had lost its dusky redness and bogginess; discharge but slight.

Thursday, wounds almost closed. Granulations appeared in perineal wounds which retarded their complete closure about a fortnight. Urethral stricture gradually dilated up to number twelve English, when the patient left the hospital.

This case well illustrated the advantages of a sublimated fossil-meal pad.

## Reports of Societies.

### PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. M. GREEN, M.D., SECRETARY.

JANUARY 10, 1885. The President, Dr. C. ELLERY STEEDMAN, in the chair.

Dr. J. R. CHADWICK reported a case of

#### GRADUAL REPOSITION OF AN INVERTED UTERUS.<sup>1</sup>

Dr. SINCLAIR spoke of a case of thirteen years' duration which he had seen in consultation with Dr. Storer: there was very little bleeding; but the patient was almost confined to bed by the constant sensation of dragging. A whole day was spent in ineffectual attempts to replace the uterus. He thought the method adopted by the reader was admirable.

Dr. BOARDMAN said the Society was indebted to Dr. Chadwick for the device which he believed was original with him. The soft colpeurynter could do no harm, whereas a hard cup would be likely to.

Dr. AMOS alluded to a case in which the baby was born suddenly, before his arrival: there was a complete rupture of the perinaem, and the uterus was found entirely inverted lying between the thighs in a pool of blood. Immediate reposition was easily accomplished; but the woman died within an hour from the effects of hemorrhage.

Dr. BAKER spoke of a case of chronic inversion in which two attempts at immediate reposition had been made before he saw the patient. In this case he first tried Tarbell's method with a Wadsworth cup and an elastic tube: having succeeded by this means in nearly getting the fundus within the os externum, he etherized the patient and after prolonged attempts lasting an hour and a half he replaced the fundus within the os and closed the latter with three or four silver sutures. Three or four days later, however, the catamenia appeared, the stitches gave way and the uterus became again entirely inverted. Taught by this failure he was led to try the gradual method of reposition, and, the patient being admitted to the Free Hospital for Women, this treatment which he there directed was most successfully carried out by Dr. F. W. Johnson. In this case he noticed that after pressure for

three days the fundus looked black and sloughy; he therefore thought it unwise to continue the pressure. As, however, the fundus was already within the os externum, he secured it there with two crossed silver-wire sutures passed through the cervix nearly up to the internal os: within twenty-four hours spontaneous reposition occurred. In another case which he admitted to the same institution and in which the same method of replacement (Wing's) was employed, the reposition was accomplished within forty-eight hours. These two cases reminded him of one he had seen some time ago in which two forcible attempts had been made to replace a supposed inverted fundus: the case proved to be a fibroid polypus; but the appearances were much the same as in the cases he had related. Regarding the method of gradual reposition, Dr. Baker did not see how Wing's method could be improved upon. By the use of the stiff stem, pressure can be controlled exactly and brought to bear accurately, the patient keeping still. He thought the soft-rubber inflated pessary would be likely to slip to one side and its efficiency in producing the pressure thus impaired.

Dr. REYNOLDS asked if cases of from thirteen to eighteen years' standing are fairly to be considered as amenable to this treatment, or only recent cases.

Dr. CHADWICK said that it did not appear to have taken much, if any, longer to replace an inversion of from five to twenty years' standing, than one of recent occurrence: both acute and chronic cases are amenable to the gradual method. In reply to the objections to his method made by Dr. Baker, namely, the likelihood of the soft-rubber pessary slipping, Dr. Chadwick said that were the vagina large this might happen; but in his case the vagina was small, and the patient got out of bed to micturate, yet there was no disarrangement of the inflated pessary. He thought the great value of his method lay in the fact that in suitable cases for its use the patient could be allowed more freedom and need not be kept so quiet as when the stiff stem was employed. Regarding the subsequent position of the uterus Dr. Chadwick said he found it retroverted after reposition, and he was unable to keep it in position without a stem pessary.

#### THE ELECTRIC LIGHT FOR PURPOSES OF EXAMINATION.

Dr. BAKER spoke of the great advantage of the electric light over reflected light in examination of the urethra. The apparatus consisted of an incandescent burner contained in a glass bulb and connected with a suitable battery. The apparatus was strapped upon the forehead and was capable of shedding a flood of light into the urethra: the result was gratifying in the extreme. The only disadvantage was that of expense.

—It is said that a substance called by the manufacturer "benefit" (evidently named exclusively from his own point of view) is made at Waltham, Massachusetts, and sold to be used in the adulteration of milk, and that it has thus far defied the usual tests.

<sup>1</sup> See page 259.

## BOSTON SOCIETY FOR MEDICAL OBSERVATION.

CHARLES H. WILLIAMS, M.D., SECRETARY.

FEBRUARY 2, 1885. Dr. E. G. CUTLER read the following:—

CASES OF CHRONIC CATARRHIAL PNEUMONIA (PHTHISIS PULMONUM) WITH ARREST OF THE DISEASE AND SUBSEQUENT RECOVERY FROM THE SYMPTOMS.

CASE I. In July, 1881, I was consulted by Mr. T. M. M., who gave the following history: He was about forty years old, with a good family record, married, and had served as a common soldier in the army during the war. While in the service he had suffered from intermittent fever and had been once wounded in the foot. Since recovery from his wound he had had frequent attacks of neuralgia in the same leg, but with this exception had been well. For some months he had been working hard to pay for a house he had bought at Beachmont, and had run down in flesh and strength and lately had had a severe cold which was accompanied by some expectoration. There had been one hæmoptysis a few days before I saw him. The appetite was gone, the bowels were irregular in their action, and his sleep was restless. For over a week he had had night-sweats, he looked haggard and dejected, and his position when sitting up was stooping. The cheeks flushed frequently and he was easily tired. He had lost much flesh and strength. There was considerable shortness of breath on exertion or going upstairs. The urine was concentrated, deposited a thick sediment of urates; there was no albumen. Pain in the lumbar region, and in the chest about the nipples, headache and dizziness were frequent complaints. He suffered from fever in the afternoon and night. The pulse was rather weak and eighty in the minute after lying quiet for a time on a lounge. Temperature a little over 100° F. when seen (at 3 P.M.).

*Physical examination.*—Inspection showed the chest to be well formed, the shoulders to be drooping from muscular weakness, and the supra-clavicular depression to be marked, probably due to emaciation. The movements of the chest were fairly natural on full inspiration, though the expansion of both upper parts seemed a little less full than normal.

*Palpation* gave increased vocal fremitus over the right upper front and an abnormally warm skin.

*Percussion* gave slight dullness above and below both clavicles, most marked on the right, and reaching down to the second intercostal space; also dullness in the upper part of the right axilla, and at the top of the lung on both sides behind. The rest of the chest in front, at the sides, and behind gave normal resonance.

On *auscultation* over the region of dullness on the right the respiratory sounds were of a bronchovesicular character, in some places approaching somewhat nearly the bronchial; on the left the respiratory murmur was weakened. There was increased vocal fremitus, and with the ordinary respiration various râles and some dry clicks, mostly on the right. Slight accentuation of the pulmonary second sound of the heart was noted.

The patient was enjoined to keep out of doors in the sun the whole day and to remain within the house after the sun went down. To sleep in a well-ventilated room alone, and to avoid all collections of people. The upper part of the chest was to be rubbed with Croton oil. Whiskey was to be taken in doses of half an ounce three times a day. Vapor of spirits of turpentine was to be inhaled twice a day, and the lungs to be fully inflated four different times in the day in the open air in the sun. One teaspoonful of the compound syrup of the hypophosphites three times a day was added, and for a cough mixture, chloroform-water, p. r. n., was ordered.

For some days there was no improvement and the physical signs and temperature increased, so cod liver oil was added to the other remedies.

The condition gradually changed for the better and after a few weeks the night-sweats disappeared, the cough became less constant and troublesome, the expectoration very nearly ceased, and the temperature returned to normal. By the end of November the physical signs had wholly disappeared, leaving a slight flattening of the upper part of the chest on the right, and a respiratory murmur, perhaps a little sharper than normal, in that region. He resumed his occupation, that of foreman of a building concern, and remained perfectly well until the month of January, 1884, when he began to run down again, and had several hæmorrhages from the lungs, amounting to about a pint in all. The physical examination gave a negative result: merely a few fine, moist râles were found in the left upper front. None elsewhere. No change in the respiratory murmur was recorded. The slight flattening of one side of the chest (right) remained. Ergot and hypophosphites were given and after a short time he became as well as usual. I have seen him on the street once or twice recently and he has seemed well.

CASE II. The first of October, 1881, Mrs. E. A. L. came under my care. She was about forty-five years old, of a long-lived family, and had enjoyed remarkably good health till the beginning of the previous summer, when she caught a severe cold which lasted a long time and she began to fail in flesh and strength.

*Physical examination* revealed the signs of some consolidation over the upper part of the right lung. There was diminished resonance down to the third rib and a respiratory murmur in the same region, somewhat concealed by fine, moist, and dry moderately coarse râles, but through which distinct bronchial expiration could be heard. There was no perceptible deficiency of expansion, and no change in the vocal fremitus detected on palpation. The voice sounds heard with the stethoscope were decidedly increased, especially above the scapula behind. The rest of the chest was resonant on percussion, and no other auscultatory signs, except a few sibilant râles in the middle of the right back, could be found. The apex-beat of the heart was in the fifth interspace, on a line with the middle of the clavicle. There was nothing recorded about its sounds. The temperature was 101.5° F., pulse 90, respiration 32.

There was no appetite; the patient was easily

tired and had occasional chills and feverish attacks. Small doses of iodide of potash, maltine, and wine of ipecac were given at first. All household cares were transferred to the daughter.

For a few days the patient continued about the same; then for several days there were numerous quite copious hemorrhages, during which merely fine and coarse moist râles were detected on auscultation. Whiskey was added to the dietary and a few days later cod liver oil to be taken with the malt.

She became progressively worse, though with no hemorrhages, till the end of October, when there was found to be flatness above and below the middle of the clavicle, in the upper part of the axilla and in the supra-spinous fossa; with bronchial breathing and bronchophony, which latter signs shaded through broncho-vesicular to normal vesicular respiration at the level of the nipple in front and the infra-spinous fossa behind. She was then given the hypophosphites, malt, whiskey, and cod liver oil, other medicines being omitted. Sleep had for a long time been much disturbed by horrid dreams, cough, and lately night-sweats had been very annoying. Soon however, her dread of nightfall changed to indifference, as some of these bad symptoms disappeared and the night-sweats could be somewhat controlled. The amount of expectoration was very considerable and was muco-purulent in character.

The patient lived up two rather long flights of stairs and it was impossible at this time to have her take exercise in the open air, for the exertion of climbing to her apartments, after a walk in the streets, more than counterbalanced any good which might be accomplished by it.

During the next two months, November and December, the consolidation extended a little and then began to soften, and by the middle of January, 1882, there were found under the right clavicle cavernous respiration, cavernous whisper, bronchophony, and the cracked-pot sound. She continued through the spring to get a little better and again worse; the cough, shortness of breath, and expectoration continuing marked. The summer was spent in Bristol, Rhode Island, where, on the whole, she did well; living out of doors most of the time, every night becoming a little hoarse. The winter of 1882-83 she remained indoors most of the time, avoided all crowded places, and steadily gained in strength and flesh and lost her fever. Glycerine and whiskey seemed to give her most relief. Fusel oil and all sorts of cough mixtures were given. Croton oil and iodine applications were frequently made to the chest. Inhalations of all sorts seemed to make her feel worse. I finally ceased visiting her at the beginning of the winter 1883, with a chest decidedly flattened at the apex, the top of the lung retracted, in comparison with the other side, an increased resonance or percussion on that side and a broncho-vesicular respiration reaching to the third rib. The cough, though still existing, was not very troublesome, but the breath was very short on going up any incline. I believed that any cavity which may have existed had contracted, leaving dilated bronchi. All the winter of 1883-84 she remained quite well and I was not called to see her till November, 1884, when she had some recurrence of expecto-

tation, cough, fever, weakness, and so forth, which after about a month of active treatment left her in her usual health. A short time ago I found her in the same condition as before the last illness, except perhaps with a little emphysematous condition of the lung.

Besides these cases in private practice of which I have kept records, I have seen two others, one in the Carney Hospital, covering a period of nearly a year, and the other a boy, kindly referred to me by Dr. E. H. Bradford, last spring. In both these the history was nearly the same (in the boy only a few months have elapsed since the case went out of care). In each the same preceding bronchitis had occurred, and when seen there was marked physical signs at the left apex, loss of flesh and strength, fever, cough, and expectoration. The same general course was pursued, and in each an arrest of the disease and subsequent recession occurred.

Several questions of great practical importance are immediately suggested in such cases:—

(1) The one of *prognosis*, which is rendered more or less favorable by the obvious cause of the disease, the early stage at which it may have been seen, the circumstances of the patient which may or may not admit of freedom from cares and anxieties, the leading of an out-of-door life, and the possibility of obtaining every modern aid in the treatment of such forms of disease.

(2) Shall the patient *go away from home*? It seems to me that first of all the home hygiene of the individual is to be thoroughly investigated by his attending physician before any proper advice can be given in this matter.

(3) How far may one permit former *occupations* to be resumed must depend on the individual case. The general proposition holding good that outdoor avocations are the only ones to be thought of.

(4) For *life insurance* such cases should be regarded as ineligible.

(5) The probability of *relapses* is great. I can do no better than read the opinion of Douglas Powell on this subject. He says: "The cure may remain permanent, but one must always bear in mind that catarrhal pneumonia is one of those diseases that are peculiarly prone to recur, resembling acute rheumatism, tonsillitis, and some other diseases, in this respect."

(6) The question of marriage seems to me to be a simple one. If it brings no increase of cares or work I see no objection, but rather the reverse.

Dr. E. N. WHITMER said the subject and the illustrations so aptly set forth in Dr. Cutler's paper are of deep interest.

It is, of course, understood by all that no disease contributes so large a percentage to the death-rate as the one under discussion; and it is also well determined by the experience of the older members of this Society that, within the past thirty years, as a result of the earlier detection of the disease, growing out of the improved methods of investigation, and from a better understanding of the physiological action of remedies, the duration of life in such cases has been greatly lengthened; but it is not equally and alike admitted that the combined influences of earlier detection, of climatic changes, of improved hygienic and dietetic surroundings, and medication

have resulted in many unquestioned cures, and I believe it is the object of this paper to emphasize this point, and to particularize the fact that cures take place even in New England.

It is well known that three of our acquaintances are now in other States, apparently fully recovered of what, at one time, appeared to be chronic catarrhal pneumonia of pronounced type. These results are largely due to climatic influences. Two are still in Colorado and one has returned, after several years there, to New York. All are in the prosperous practice of their profession.

Such instances are not infrequent, and illustrations of this class of cases may be found in the experience, or within the knowledge, of each of us.

When General Hooker was placed in charge of the Army of the Potomac, Mr. Lincoln wrote that memorable letter in which he distinctly stated that he appointed him to this most important command, not for the reason that he believed the General to entertain discreditable sentiments, and to have failed to give loyal support to General Burnside, but in spite of these facts: and what we seek to-night are not the evidences of curative results of the best known influences collectively employed, but cases of cures wrought in spite of the unfavorable influences exerted by our own inhospitable climate—cures in that class in our communities originating the largest number of such cases. I mean among the children of foreign-born parents whose heredity is free from such taint.

I can add but little to strengthen the facts presented by Dr. Cutler, except by citing cases similar to his in character and result—cases coming under my own observation.

I have notes of four in which the rational and physical signs were unquestionably those of chronic catarrhal pneumonia, in each of which the opinion formed by me had been anticipated, or even accepted, by our best experts; in all of these there were local and constitutional evidences of advanced pulmonary disease, and, at intervals varying from ten months to three years from the earlier observations, repeated and careful examinations failed, disease remaining *in situ*, or to cast any doubt upon the full recovery of these four patients.

These cases, which are alluded to for the purpose of adding to those described by Dr. Cutler, have strengthened the opinion I have formed, from carefully listening to his valuable paper, and from my own opportunities for observation, that now more than formerly, and now unquestionably, influences, positively curative, are brought to bear, even here, upon the disease known as chronic catarrhal pneumonia.

Dr. F. C. SHATTUCK expressed his full assent to what had been said by the reader and previous speakers as to the gradual improvement which has been made, and is coming about, in the outlook for cases of incipient and limited phthisis. Recovery or arrest cannot safely be predicated, however, soon after prolonged observation; inasmuch as we meet with many cases in which the disease remains stationary for a time, or even retrogresses, the rational signs showing more or less improvement also, but which end fatally nevertheless.

After alluding to the case of a gentleman whom

he believed to have contracted the disease from his wife, she being phthisical at the time of marriage and dying within a year, and the husband finally recovering entirely, Dr. S. went on to say that the experience of those who had been long in practice is of especial value with regard to this point. Dr. Flint published, in 1875, an analysis of six hundred and seventy cases of phthisis which had come under his observation and of which he had notes: in forty-four of these there was recovery and in thirty-one arrest; many of the cases were followed up for more than twenty years after they first came under his notice.

The reader justly emphasized the vital importance of fresh air in the treatment of this disease. Possibly some of those present may not be familiar with a simple means for ensuring a sun and fresh-air bath. If a room with a southern exposure is at command, on the coldest winter day a patient who is too feeble, from any cause, for active exercise, can be seated at the wide-opened window, wrapped up in blankets and shawls. That very morning the speaker found two of his patients thus established, and, sitting himself in the sunshine without hat or coat in perfect comfort, made his visit. Unfortunately, it is not every patient for whom such an expedient is desirable who can be persuaded to adopt it, some people preferring to suffer rather than appear peculiar to their opposite neighbors.

Again, with reference to cough; those of us whose personal experience of coughing is limited to an occasional attack of bronchitis do not always realize what hard work it is for a debilitated person. The secretion which has accumulated during sleep must be got rid of in the morning, and the aid which is afforded by the administration of a cup of very hot broth, cocoa, or the like, as soon as possible after waking, is very remarkable.

In conclusion, the speaker expressed his surprise at the unanimity with which the reader and previous speakers used the term "chronic catarrhal pneumonia," a term expressive of pathological doctrines once in vogue, but daily losing ground. There is a process to which the term catarrhal pneumonia may be properly applied, the lobular pneumonia namely, so common in the extremes of life, and as the type of which may be regarded the affection that so often proves fatal after whooping-cough and measles. The term, as applied to the disease under discussion, is inaccurate and misleading; while the terms phthisis and consumption involve no pathological theories, correct or erroneous, those who believe that the discovery of the bacillus has settled forever the pathology of the disease can use the term tuberculosis.

Dr. FIZZ observed that he had been reminded during the discussion of the remark of the old Berlin physician, that "sooner or later most of us become more or less tuberculous." Post-mortem examinations show almost beyond question that recoveries from phthisical processes in the lungs are of relatively frequent occurrence.

Such examinations suggest the importance of limitation in the prognosis of pulmonary phthisis. It is well known that the apices of the lungs usually contain the remains of the obsolete processes, but

these may be found in the lower as well as upper lobes and in the lowermost part of the upper lobe, in front or behind, as well as at its apex. Evidences of healed phthisis are usually found limited to one part of the lung, and clinically the cases afford the most favorable prognosis in which, as in those reported by Dr. Cutler, there is no evidence of a localization of the disease in several centres more or less widely separated.

The possibility of a prolonged, useful, and enjoyable life, with evidences of extensive destruction of the lung from phthisis, was referred to and illustrated by a case which had been under observation for a number of years.

The patient, seventy-four years of age, was considered, by competent observers, more than thirty years ago to be seriously ill of pulmonary consumption. He gave up active business and spent several years in Europe. While in London he suffered from an acute attack of severe hæmoptysis. The eminent physician who was called upon for relief doubted if the patient could live a week. During the quarter of a century since his return from Europe he has been able to lead an outdoor life, to attend to his affairs, and to find abundant opportunity for enjoyment. The phthisical symptom of longest persistence, and for years a considerable annoyance, was cough with profuse expectoration. It never left him, but ceased to become a serious burden. Dilated bronchi, emphysematous lungs and a hypertrophied heart were developed in the course of years. Finally a weakening of the heart preceded an acute attack of broncho-pneumonia, which quickly ended in death.

The remarks of Dr. Shattuck, with regard to terminology, deserved attention. It seems undesirable to give up the terms chronic, catarrhal, and cheesy in connection with the pneumonia of phthisis. Since the discovery by Koch of the bacillus tuberculosis and its importance in the etiology of pulmonary consumption, there is a growing tendency to become satisfied with the use of tubercle and tuberculous in connection with the diagnosis of phthisis.

This tendency to confound etiology with anatomical characteristics might be regarded as retrograde in connection with the important advances in physical examination which permit the physician to discriminate between various anatomical changes found in the lung.

In evident solidification of the lung, although tubercles may be present, the greater part of the new material, in most cases, is to be regarded as an accumulated inflammatory product upon the alveolar wall or surface. Though united with tubercle, and perhaps caused by the tubercle-bacillus, the mass is to be recognized clinically as the manifestation of a chronic pneumonia, and the association with tubercle is to be regarded as mainly inferential.

In reply to Dr. Fitz, Dr. F. C. Shattuck remarked that he could not see the expediency of employing a term after experience had shown that it is incorrect and consequently misleading. He also wished to protest against the view maintained by Dr. Woodgett that a hopeless prognosis is to be based on the discovery of the bacillus tuberculosis in the

sputum. The discovery is altogether too recent and the observations too few to warrant such a position. At present the bacillus is diagnostic rather than prognostic; let us only recall the great gravity at first attached to the presence of casts in the urine and reflect on the change of opinion which prolonged and widespread observation has brought about.

DR. TARBELL spoke of the importance of this disease in relation to life insurance. The Mutual Life Company of New York have published the results of thirty years' observation, from which they have made a rule that no person is to be insured who has had chronic catarrhal pneumonia with hæmorrhage where the disease came on after adult life, and no person is to be insured among whose uncles, aunts, or grandparents there are two cases of death from this disease; on young people, however, who have recovered from this trouble, and after ten years remain in good health, an insurance may be made.

DR. LANGMAID spoke of the complications which often occur in cases of this disease, but he considered an uncomplicated case of chronic catarrhal pneumonia not by any means hopeless, for he had seen a number of recoveries. Great attention should be paid to alimentation, and the patient should remain under medical supervision for one or two years.

DR. J. B. AYER mentioned the case of a student who had hæmoptysis with solidification of upper lobe of left lung. He was sent to the Sandwich Islands by the way of the isthmus, and he now seems perfectly well.

DR. F. H. DAVENPORT said that, while in California and Colorado, he had seen a number of people who were in good enough health to do business there, although they could not return to the East, and when they left home had not been able to do anything.

DR. FOLSON mentioned the statistics of Massachusetts which have been kept carefully for forty years and show a decrease of mortality from phthisis, about one sixth of the total death-rate being now caused by this disease. He thought physicians were too much inclined to give an unfavorable prognosis, and he advised keeping the patients quiet in some place where they could have attention and comfort, rather than constant shifting of quarters in search of a more favorable climate.

DR. BLODGETT called attention to the question of the bacilli of tuberculosis, and thought their presence in the sputa would lead to a much more unfavorable prognosis.

DR. CUTLER said the question of bacilli was too young to enable us to draw a dividing line between favorable and unfavorable cases, on account of their presence or absence.

DR. V. Y. BOWDITCH mentioned a case where with dulness and loud bubbling râles under the clavicle there were very abundant bacilli of tuberculosis in the sputa; the patient went to Texas, where she passed the winter in the open air; on coming back she caught cold in New York, but without developing any serious symptoms; she is now passing the winter in the Adirondack region, apparently perfectly well.

## PATHOLOGICAL SOCIETY OF PHILADELPHIA.

THURSDAY evening, February 12, 1885. The President, DR. SHAKESPEARE, in the chair.

## A CASE OF CARDIAC (?) ANEURISM.

Presented by Dr. JOSEPH S. NEFF.

William N., colored, aged forty. Family record good. No evidence of venereal disease. His previous history shows nothing of importance until two and one-half years ago, when he had acute inflammatory rheumatism. I could not obtain any satisfactory history of endo- or peri-cardial inflammation at that time. He appeared to make a good recovery and remained well until one and one-half years ago, when he noticed palpitation of the heart and dyspnoea upon slight exertion, soon followed by cough which was rather persistent. There was no œdema at this time, at least not sufficient to have attracted his attention. He improved upon rest and some medication received at a dispensary. After this first attack until admission to the Philadelphia Hospital, he was enabled to work, although being always susceptible to palpitation and shortness of breathing upon extraordinary exertion, with one exception; which was one of his so-called attacks, and described as "catching cold," which would increase the above-named symptoms to such an extent that he was compelled to remain in the house for several weeks last August. Here, again, there was no sudden exacerbation of the symptoms alluded to.

He was admitted to the medical ward of the hospital on November 25, 1884, at which time he presented the following

*Conditions.*—Orthopnoea intense, cough persistent and troublesome, accompanied by hæmoptysis, palpitation of the heart excited by moving in bed, general anasarca, skin on limbs and scrotum cracking in places from distension, deep pitting on pressure, even on chest, face, and forehead. Bowels constipated, urine scanty, containing one tenth of one per cent. of albumin. No casts. Pulse weak and frequent, although the peculiarity known as Corrigan's pulse was distinguishable.

*Physical examination* revealed marked and peculiar pulsation of the great vessels of the neck. Impulse of heart seen, disseminated over an area of about two inches. Cardiac dullness extended from upper border of third rib on left side of sternum to liver, and horizontally on a line of fifth rib, from three fourths of an inch to the right, to four and a half inches to the left, of sternum. The apex-beat being felt in the seventh interspace (one and one-half inches to the left and two and one-half inches below the nipple).

Upon auscultation a loud blowing diastolic murmur was heard, commencing immediately below the aortic valves on a level with third rib, and transmitted downward and toward the left, being quite loud at the ensiform cartilage and apex, with its seat of greatest intensity over the left side of sternum on a level with the fourth costal cartilage. This murmur was not transmitted in any other direction. As to its exact time, I would state that it commenced immediately after the first sound,

lasting through the second, and continuing almost through the period of rest.

A systolic murmur was also heard at the base of heart and was transmitted toward both infra-clavicular regions, and at times was heard in the carotids. It commenced with the first sound but did not last through it. It was not heard over the body of the heart. In the region of the axilla a third murmur was heard, systolic, which could be distinctly separated from the preceding, as being less harsh and occurring later in the systole. It was also heard over the left auricle, and as far to the left as the axillary line. Was not audible posteriorly.

Physical examination of the lungs showed a condition of passive congestion. There was no nervous phenomena excepting some slight delirium, lasting for a short time and due to imperfect aëration of blood.

The diagnosis was undoubted aortic insufficiency with dilated hypertrophy of left ventricle and some mitral regurgitation. Under treatment improvement commenced at once and continued until December 11th, when he was able to walk around the ward without discomfort. Cough had disappeared. No shortness of breathing or palpitation without undue exertion. Dropsy almost entirely absent. The urine still contained a trace of albumin. Physical signs of the heart were unchanged, save an impulse increased in force. Pulse was seventy-eight strong and retaining to a marked degree the "trip-hammer" characteristic.

The general condition remained unchanged until December 30th, when it was noticed that the œdema was making headway; returning dyspnoea, etc. This gradual increase in severity of symptoms continued and on January 5th there was complete hæmoptysis, the physical signs being the same again as on admission, excepting dullness and bronchial breathing over both bases of the lungs posteriorly. Patient gradually grew worse and died on January 19th.

*Autopsy* made by Dr. Shakespeare, the pathologist of the hospital, the notes of which were written by my resident, Dr. Hickman, and are as follows:—

External appearances: General anasarca, especially of lower extremities; most marked in the left.

Heart—Pericardial cavity contained some serous fluid, but no evidences of pericarditis. The heart was greatly enlarged, the enlargement being principally in left ventricle.

Right ventricle contained dark, clotted blood, the wall being one fourth of an inch in thickness, very firm, and marked post-mortem staining present. Nothing else noteworthy on this side.

Left ventricle was greatly dilated and the wall much hypertrophied, being fully three fourths of an inch thick. The endocardium was intensely stained post-mortem. Ventricular wall was quite soft. The ascending aorta also showed intense post-mortem staining of inner lining, and the latter was in a condition of moderately extensive arteritis.

Coronary arteries appeared normal at their mouths, the right being somewhat dilated and more or less atheromatous; mitral orifice appeared normal, also the surface of the auricle. The ventricular

endocardium presented nothing noteworthy except post-mortem staining.

There were on anterior leaflets of mitral valve at base a few endocardial yellow streaks running horizontally.

At juncture of left cusp of aortic valve with ventricular cusp there was a mass of cheesy material beneath the endocardium about half an inch in diameter. The mitral cusp showed a rupture through and into the pocket of posterior cusp where the two joined; the latter cusp was also perforated in its right third and there was an aneurismal cavity extending into the upper portion of septum between the ventricles. The apex of the dilatation corresponding to the upper septum of right ventricle. The aneurismal sac showed a dilatation toward left ventricle and a rupture into the latter by an orifice admitting the end of thumb, the upper border of the opening being formed by the two affected leaflets above mentioned. There were some vegetations upon under surface of aortic cusp. The aneurism was the size of a walnut and contained no clots.

Both pleural cavities contained sero-sanious fluid. No adhesions except in one point at lower lobe. The two lobes are slightly collapsed; they presented no other abnormal appearance except the existence of two embolic infarcts. One small, wedged-shaped, size of a hazelnut, superficial near the inner edge of upper lobe at its anterior surface; pleural surface congested.

Another the size of an hen's egg, projecting above the surface at the inner edge of lower, and at the outer edge of upper, lobe, about two inches from base of lower lobe, at its anterior aspect. The two lobes are adherent at the point of the infarct and their substances appear to run together. The cut surface showed the infarction to be made up of tissue of both lobes, mainly of lower, and a line of division of the two lobes is quite perceptible. The area of infarct is dark red and granular, sharply outlined. At centre of the pleural surface of this large infarct there was an irregular area of reddish substance. No pleuritic adhesions with chest-wall corresponding to this infarct and no decided pleuritis.

The upper lobe of the right side contained two infarcts, size of a hickory-nut, along its anterior lower edge. Middle lobe, one in a similar position. Lower lobe contained four, varying in size. This lung presented nothing else abnormal.

Liver normal in size, flabby and smooth surface. Nothing else abnormal except some congestion and probable increase of fibrous tissue, it being extremely difficult to push finger in the cut surface.

Spleen normal in size, pulpy, dark brown in color, with slightly increased thickness of the capsule.

The kidneys were normal in size, and presented no marked unhealthy appearance, these organs being so stained post-mortem as to make it impossible to judge of their condition. Amount of cortex appears normal.

The pathological change seemed to originate at the sinus of Valsava and penetrated into the septum, then causing a bulging of the two affected aortic leaflets, making a valvular aneurism (secondary), which ruptured into left ventricle. Clinically, these cases

are of little value, as none have been diagnosticated other than valvular disease. It seems quite remarkable, however, that there was no sudden onset of symptoms to mark the rupture of valves.

Dr. TYSON said that the aneurism seemed to have its origin in the sinus of Valsava, whence it had dissected the muscular tissue of the heart toward the base of one of the leaflets of the tricuspid valves without perforating into the cavity of the right ventricle. The perforation of the semilunar valves of the aorta he thought secondary, for if it had exerted its force primarily in this direction it would have perforated into the left ventricle. The origin of the infarcts does not seem at all clear. They ought, of course, to have come from the right side, as they were of large size, and could, therefore, hardly have come around from the left heart through the systemic capillaries into the right heart, and thence into the lungs.

Dr. HUGHES said that we might, perhaps, explain the infarctions by means of the bronchial arteries, as this was the route said to be pursued by emboli to the lungs.

Dr. NEFF said that the œdema, as described, was rather remarkable; but the notes would show that there was albuminuria in addition to the encephalic circulation and pulmonary congestion; this œdema of the upper extremity was not constant. As far as the infarcts were concerned, he was anatomically at a loss. In his mind they were always directly connected with the lesion in the left heart, as it was difficult to see how the necessary thrombi could originate in the right side, as the postmortem revealed no signs of disease here, excepting the projection of the aneurismal bulging, which evidently did not interfere with the circulation. Congenital aneurisms, as described by Peacock and others, were lower down, as a rule, in the undefined space, and they were rarely, if ever, the direct cause of death, unless accompanied by endocarditis. The rupture of the cusps was due to their weakened condition, dependent upon calcareous degeneration.

Dr. TYSON was much struck with the explanation given by Dr. Hughes as to the origin of the infarcts, and thought we paid too little attention to the bronchial arteries as a factor in pulmonary infarction.

Dr. SHAKESPEARE agreed with Dr. Hughes, and thought that Columbus, through his celebrated study of the embolic processes, had shown that pulmonary infarction usually takes place by way of the bronchial arteries, which are, according to him, of a terminal character.

#### SARCOMA OF RETRO-PERTONEAL GLANDS.

Presented by Dr. JAMES TYSON.

Samuel D., a gardener, aged forty-three, unmarried, was admitted to the Philadelphia Hospital August 15, 1884. There was no family history of phthisis or cancer, nor has he ever had syphilis. Three years ago he had a tertian intermittent fever, which lasted a week only. He thought he had injured himself by heavy lifting in June, 1884, and dated his illness to that time, although he admitted having experienced some discomfort prior to that time in the constant stooping that his occupation required of him. About July 1st he noted that his feet and legs began to swell; also that the swelling

would partially disappear at night. At this time he also began to have, at irregular intervals, severe pain in his legs, especially the left leg. He was subject to alternate constipation and diarrhea. This was about his condition when admitted. There was also noted a swelling immediately below the edge of the ribs on the right side, which was ascribed to enlargement of the liver, the dullness occasioned by it being directly continuous with that of the latter organ. His condition changed slowly, but gradually the tumor became more evident, and the pain in the right leg increased. He was certain when admitted there was more pain in the left, and that at that time could not lie on the right side, while by November 20th he could rest more comfortably on that side. At this time the dullness extended in the maxillary line from the sixth rib to a line drawn transversely from a point one inch above the anterior superior spinous process of the ilium. In the median axillary line the dullness extended from the ninth rib to the crest of the ilium, and posteriorly from the eleventh rib to the same point. The tumor was bounded on the left and below by a line drawn from the umbilicus to a point one inch above the anterior superior process of the ilium, and thence obliquely to that bone. There was distinct bulging in the right flank and right lumbar region. The circumference of the abdomen through the umbilicus was thirty-four inches. There was greater fullness in the right flank laterally and posteriorly, and the veins over this region and the right half of the abdomen were distended. From December 1st he was confined to his bed, being unable to stand in consequence of what he described as weakness in his legs, especially the right, and he suffered so much pain as to require the regular administration of morphia. The circumference through the umbilicus was thirty-six inches. The sulcus at the border of the ribs had become more marked. There was at no time jaundice, and while he gradually emaciated there was no cachexia.

At first no thought was entertained that did not suppose the tumor was in some way associated with the liver. Abscess, lardaceous disease, and cancer were, however, excluded by the absence of the other essential symptoms, and it was finally thought we had most likely to do with a hydatid cyst. This was based on obscure sense of fluctuation at the most prominent part of the swelling to the right of the umbilicus. Accordingly, on December 12th, I introduced an exploratory needle to the depth of four inches at this prominent spot. A few drops of bloody fluid only were drawn, which showed upon microscopic examination to contain no distinctive elements. Forced by the results of this operation to abandon the liver as the seat of the disease, the kidney was then selected as its probable seat, although repeated examinations of the urine had shown that while it was somewhat diminished in quantity it was otherwise normal. It was twice ascertained, however, that it did not contain iodine after the administration of five grains of this substance. Soon after the first of January, 1885, his stomach ceased to retain food, after which he declined more rapidly, and died January 16th. As the disease progressed the tumor presented through the abdominal walls, and also to palpation, a more uneven outline, which

could not, however, be described as nodulous. At the autopsy, there was noted on inspection adema of the right leg, and a tumor occupying the space between the ribs and ilium on the right side, extending three inches beyond the median line. It was lumpy or uneven. The hand could be pushed up a short distance between the ribs and the surface of the tumor. On section, the visceral and parietal peritoneum appeared normal, and the omentum partially covered the abdominal contents, but was adherent only in the right iliac fossa. The colon was displaced, and, commencing at its head in nearly the normal situation in the right iliac region, extended upward and to the left along the border.

The right kidney was found closely applied to the front of the tumor, and so closely that it was at first overlooked, and the tumor thought to be one of that kidney. It was compressed, flattened, thinner than an average hand, and smaller in circumference than the normal organ. The minute examination of the right kidney revealed a very interesting condition. The tubules bore evidence of the compression to which the organ had been subjected. The cells were everywhere compressed and the tubules narrowed. There was a slight hyperplasia of intertubular tissue, especially about the malpighian bodies. The ureters and bladder were normal.

The pericardium and heart were normal, the left pleural sac contained a small quantity of bloody serum, and there were a few trifling adhesions.

The left lung contained, along the outer anterior edge of the upper lobe, three inches from its base, a moderately formed nodule half an inch in diameter, pinkish-gray on section, and projecting above the adjacent cut surface of the lung. Two similar reddish-gray nodules were found on the lateral aspect of the lower lobe of the lung, about four inches from its base. They were about an inch apart, about three fourths of an inch in diameter, and projecting as much from the lung almost as sessile tumors. There was another small tumor on the posterior edge of the base of the lobe. There was more than the usual adhesion between the two lobes of the lung. The lower lobe of the right lung was much adherent to the diaphragmatic as well as the thoracic pleura. There was a warty excrescence about three fourths of an inch in diameter attached by a small pedicle to the upper lobe and a still smaller one at its anterior edge. The nodules in both lungs were encapsuled. The tumor itself was lobulated, and occupied the entire right side between the edge of the ribs and the pelvic bones, and extended even to the left of the median line in the neighborhood of the umbilicus. It presented the same obscure sense of fluctuation, and, upon section, the lobes of which it was composed, each one of which appeared to correspond with an original lymphatic gland, protruded in its central position, and presented a uniform pinkish-gray surface, of moderately soft, but by no means diffident, consistence. The microscopic examination revealed throughout the structure of a sarcoma of the tumor mass, to the region of the spleen, where it turned inward and made two or three twists along the left side of the abdomen. The right side of the liver was slightly enlarged, but the organ was otherwise

normal. There were no adhesions whatever and its surface was smooth. It was unusually firm on section and the lobules seemed to have been compressed.

The spleen was slightly harder than usual, but otherwise normal. The pancreas and stomach were both placed backward and to the left. The former was normal, as was also the latter, except that there were a few punctiform extravasations in its cardiac end.

The left kidney was found buried beneath the left portion of the tumor, and appeared one third larger than normal. The capsule stripped off easily, leaving a smooth dark-red surface. On section the cortex seemed slightly broader than in health and was darker in hue. These sections, studied microscopically, showed a normal histology. The organ was simply hypertrophied.

Dr. J. H. Musser asked whether the tumor moved synchronously with respiratory movement, for if connected with the liver, such would be the case. He would also like to know whether hydatid fremitus, so called, was present and by which signs the diagnosis of hydatid tumor was made. Dr. Musser also asked the position of the left lobe of the liver, for if displaced it would have indicated possible dislocation of that organ, a condition well known to ensue in tumors of the right kidney on account of the direction of their growth. He thought a tumor of the right kidney could have been eliminated, by the direction of the growth of the present tumor, namely, downward and outward.

Dr. Tyson said that with regard to its mobility it was certainly a fixed tumor. There were no signs of hydatid fremitus, this diagnosis having been arrived at by exclusion, and the obscure sense of fluctuation which could be detected.

Dr. SHAKESPEARE said there was also a small lobulated tumor on the left side of the vertebral column entirely covered and concealed from view by the fibres of the head and belly of the left psoas muscle. He suggested that the origin of the larger right-sided tumor may possibly be explained in the same way; for not only the kidney and ureter, but also the large vessels, were pushed forward and to the left border of the tumor mass, and no remains of the head or belly of the right psoas muscle could be found. The location of the retro-peritoneal glands of the lumbar region is mainly in front and around the main vessels. They are far in front of the psoas muscle, and can with difficulty, under all the circumstances of this case, be regarded as the origin of this large tumor. Dr. Shakespeare would ask Dr. Tyson whether the pain complained of was referred to the anterior crural or the sciatic nerves.

Dr. Tyson replied that he could not be certain whether the pain in the left leg was along the distribution of the anterior crural, but thought that it was. Certainly in the right leg the pain pursued the course of the branches of distribution of the sciatic nerve.

M. Powell, of this city, at whose request I saw the little patient and for whom I made the post-mortem examination. Lizzie P., aged two, of a strumous diathesis, was first seen by Dr. Powell on February 2, 1885, when she appeared to be suffering from catarrhal fever, but at his next visit, two days later, a diphtheritic membrane was easily recognizable over the uvula, tonsils, and half arches.

The child grew worse, the membrane increasing, the cervical and post-cervical glands enlarging, pulse running high, hyperpyrexia, and the case rapidly assuming a malignant aspect.

On last Sunday, the 8th, after consultation, the plan of treatment was slightly changed, apparently to the child's benefit, as she improved until about eight in the evening of the 11th, when her respiration was noticed to become fish-like, extremities cold, pulse high and thready, increasing apnea, and sudden death at 9.30 p.m.

Postmortem fourteen hours after death. Female child, fairly well nourished; in the right eye is to be seen a corneal opacity, probably the cicatrix following phlyctenular keratitis.

The larynx unfortunately was somewhat mutilated in removal, as an incision in the neck was not permitted. Some edema may be noted and in the recent state areas of hyperemia were observed, probably the seat of membrane.

The trachea presented these areas much more plainly.

The glands at the root of the lungs and along the trachea are much enlarged and indurated; one is lodged just at the bifurcation of the trachea and probably had some causal relation, through pressure, to the emphysematous condition of the lungs.

Thorax: *lungs*, the pulmonary and costal pleura are adherent, as is also the diaphragmatic; the lobes of the lungs are bound together by slight adhesions. In numerous spots over the lung tissue are to be seen small areas of emphysematous dilatation. Cross-sections of the bronchioles show exuding muco-purulent matter well aerated. No effusion is to be seen in the pleural cavities.

The heart appears to have undergone some dilatation of its right cavities; the valves are normal; the left side is forcibly contracted, with normal valves. Contrary to our expectation no clots were seen either in the heart, pulmonary artery, or aorta, with the exception of a very small one entangled in the cordae tendinae of the right ventricle. No effusion within the pericardium.

Liver normal, spleen somewhat enlarged, stomach contained a large quantity of undigested milk; over its surface were seen numerous centres of ecchymoses.

Kidneys and brain not examined.

The cause of death in this case becomes an interesting inquiry. The child was practically well of the diphtheria and was progressing nicely toward convalescence when suddenly signs of apnea appear, deepening into death. As was noted above, the right auricle and ventricle appear to have undergone severe dilatation. This, to my mind, was the cause of death in our patient's case, as sudden and considerable dilatation of the cardiac cavities, more especially of the right heart, may be remarked at the bedside, and in many febrile cases causes sudden death from heart failure.

LARYNX, TRACHEA, LUNGS, AND HEART FROM A CASE OF ANGINOSE DIPHTHERIA.

Presented by W. A. EDWARDS, M.D.

This case occurred in the practice of Dr. William

Dr. TYSON said that the cause of death in diphtheria seemed best explained by the theory of Dr. Edwards, which is a very reasonable one, and that this dilatation of the heart cavities was the result of a rapid fatty degeneration of the heart muscle, a condition of frequent occurrence. Theoretically digitalis was considered useful in this form of heart failure, but if due to fatty degeneration it would, of course, produce no effect. Affections of the cardiac ganglia, he believed, produced this heart dilatation.

Dr. EDWARDS said that Dr. Beverly Robinson had reported examinations in which he could find no fatty degeneration, and Dr. Edwards himself, in three cases of rapid dilatation of the right cavities occurring in typhoid fever, had failed to find evidences of fatty degeneration. These cases were published in the medical journals about one year ago.

#### RHODE ISLAND MEDICAL SOCIETY.

SIXTY-SIX Fellows attended the usual quarterly meeting, which was held in Lyceum Hall, Providence, March 19, 1885, the President, Dr. O. C. WIGGIN, in the chair.

As recommended by the Board of Censors, Drs. Charles A. Stearns and Horace N. Williams, of Providence, were admitted to fellowship.

The following delegates were elected to the New Orleans meeting of the American Medical Association, namely: Drs. Herman Canfield, J. W. Sawyer, O. C. Wiggins, A. G. Browning, J. H. Eldredge, F. B. Fuller, Benjamin Greene, Ariel Ballou, G. H. Kenyon, Job Kenyon, H. G. Miller, Charles O'Leary, G. A. Pierce, H. Terry, S. Hunt, W. E. Anthony, A. E. Tyng, W. J. Burge.

A communication was received from the Association of Superintendents of American Asylums for the Insane, relative to the emigration to the United States of the defective classes of foreign countries. The circular represents that the foreign-born element of our population constitutes one eighth of our people but furnishes one third of our criminals, paupers, and insane; and contains resolutions asking Congress for such legislation as will restrain the immigration of persons likely to become public burdens. The resolutions were endorsed.

Dr. CHARLES H. FISHER, secretary of the State Board of Health, presented for distribution a pamphlet recently issued by the Board, and entitled "Suggestions in relation to Asiatic Cholera."

Dr. R. F. NOYES reported in detail an unusually severe case of typhoid fever complicated by miscarriage. The patient, married, aged twenty years, between three and four months pregnant, and thirteen days sick with typhoid fever, was admitted to Rhode Island Hospital, with temperature 101.2° F. and pulse 132. She was placed in a private room and the "specific treatment" of enteric fever by carbolic acid and iodine instituted, with nourishment, stimulants, and sponging. Her condition remained essentially unchanged until the sixteenth day, when she became delirious and uterine hemorrhage occurred. This was promptly controlled by position and the use of ice, immediately after which the vagina was thoroughly

tamponed. Expulsive pains began the next day; the fetus and placenta were delivered and firm uterine contraction secured. During the night following, the patient failed rapidly; the pulse rose to 168 and was occasionally absent at the wrist, and she had numerous attacks of syncope from which she was roused by the hypodermic administration of brandy. The "specific treatment" was discontinued, and from this time on, the stomach was allowed milk and brandy only, while opium and quinine were given by the rectum. During the next week her condition was critical, the temperature being one and a half to two degrees higher in the morning than in the evening and twice rising to 105.5° F. From the twenty-fifth day, when the temperature fell to 99.5° F., convalescence was continuous.

Dr. A. B. BRIGGS reported a similar case in which the temperature reached 105° F., for six days in succession and then abated. In the third week there was a relapse, which subsided, and abortion followed. The patient was eight months pregnant, and made a good recovery. The child was still-born and much emaciated.

The PRESIDENT had seen two cases of typhoid fever in pregnant women. In one case which happened during the third or fourth month of pregnancy the fever was mild and the patient recovered, giving birth in due time to a healthy child.

The second patient was in the last month of pregnancy. Labor came on during the twelfth day of the fever, while the delirium was at its height and was completed without the mother's knowledge. The child lived to surprise its mother when she recovered consciousness, ten days later.

The President defended hospital treatment of typhoid fever. It is a popular error that these cases can be cared for better in their own homes. Hospital care and nursing are very successful in the management of this disease if the case is brought in early in the illness. The danger lies in removal. If a patient has been some days sick with enteric fever he had better remain even in miserable surroundings than risk the dangers of transportation.

The paper was further discussed by Drs. White, Hunt, Ariel Ballou, Newhall, and A. A. Mann.

Dr. B. R. SYMONS presented a paper on the "Pathology and symptoms of rachitis."

Concerning the prevalence of rachitis among the poorer classes of Germans, Dr. G. T. Swarts suggested that it might be due to the diet, which, in their native land, often consists almost wholly of bread made without salt.

Dr. E. B. SUMN reported a case of cancer of the intestinal tract in which there was found complete occlusion of the descending colon, the transverse colon being enormously distended with gas.

Dr. G. T. SWARTS reported a similar case, where, at the autopsy, the transverse colon was found distended to six times its normal diameter. In this case there had been paralysis, which was supposed to be due to pressure on the nerve roots at their exit from the spine.

Dr. W. O. BROWN suggested that we often overlook the true pathology of cases in which paralysis has been a symptom by failing to examine the spinal cord. In such instances a post-mortem exami-

nation should be considered incomplete which omits inspection of the cord.

Dr. G. W. PORTER reported a case of pyo-salpinx treated by Tait's operation. The patient, aged twenty-seven years, was always delicate, menstruated first at sixteen or seventeen years, and had always suffered from dysmenorrhœa. Married at twenty-one and had a miscarriage at three months soon afterward. No children. She jumped from a wagon in the fall of 1879, and at once began to have painful micturition, from which she had suffered ever since. There was also backache and "burning ache" in both hips, worse at night. She had been treated locally by pessaries, etc., and had suffered from occasional pelvic inflammation. Soon after last Christmas she began to notice a pain in the left hip different in character from what she had before, often with nocturnal exacerbations. No chills. When Dr. Porter saw her, in January, he found the right ovary prolapsed and a mass on the left side of the uterus, very sensitive, which increased rapidly in size, gradually assuming the sausage shape of a distended and bent Fallopian tube.

As soon as the nature of the trouble was apparent an operation was proposed, and was performed in a private hospital in Providence, February 14, 1885. An abdominal incision was made in the median line just above the pubes, sufficient to admit two fingers, and the left Fallopian tube drawn up, some slight adhesions holding the uterus and tube backward being broken up by the fingers. The ovary was found, fully twice its natural size, completely encircled by the distended tube, which was everywhere very firmly adherent to the ovary. A double ligature was passed through the broad ligament and tied firmly, on one side close to the horn of the uterus and on the other embracing the outer portion of the broad ligament. The tube and ovary were then cut away, a little pus escaping at the uterine end of tube; but this was carefully prevented from touching the peritoneum. There was slight oozing from breaking up of adhesions, but otherwise no hemorrhage. The other ovary, slightly enlarged, was felt prolapsed into Douglas's pouch and quite firmly bound down by adhesions. This was left undisturbed. The tube on the right side was not distended. The pelvis was sponged out carefully, and the abdominal wound closed by silver sutures so placed as to bring into contact a considerable surface of the peritoneum on each side of the line of incision. The abdomen was covered with a thick layer of salicylated cotton. The carbolic spray was not used, but hands, instruments, and sponges, were kept thoroughly carbolized.

The patient took ether well. There was no apparent shock from the operation and very little nausea from the anæsthetic. She made a rapid and uninterrupted convalescence, having scarcely any pain and no tympanites. The only time of serious discomfort was from efforts to move the bowels on the ninth day.

The temperature on the morning of the third and evening of the fourth day was 100.2° F. At no other time did it exceed 100°. Pulse did not reach 100. Several of the superficial sutures were removed on the eighth day, but the deeper ones

were left longer, the last remaining two weeks. She returned home in three and one-half weeks, with excellent appetite and gaining strength daily.

## NEW YORK ACADEMY OF MEDICINE.

STATED meeting March 19, 1885.

### THE TREATMENT OF PATIENTS IN THE TEMPLES OF ÆSCULAPIUS.

PROF. A. G. MERRIAM, of Columbia College, by invitation delivered a lecture on the above subject. Much that had been made known since the brilliant discoveries of Schliemann, he said, had been almost immediately buried again by consignment to archaeological periodicals and monographs. It was to the labors of the Athenian Archaeological Society that we were indebted for a knowledge of the great temples of Æsculapius at Athens and Epidaurus. As a preliminary to his subject proper, the lecturer reviewed the opinions of a number of authors of antiquity in regard to the subject of disease and medicine. The idea was universal among the ancients in India, Egypt, Palestine, and other countries, as well as Greece, that diseases were due to the anger of some offended god or demon, and that in order that a cure might be effected it was necessary that this supernatural agent should be appeased. Having referred to a number of allusions to disease and injuries, and their cure by the interposition of divine power, in the Homeric poems, he stated that there was no mention whatever in Homer of such a thing as resorting to temples in order to be healed. This became the practice at a later period, when hero-worship was in vogue. In speaking of medicine in the seventh and sixth centuries B.C., he mentioned the teachings of Solon, and, in the fifth century, of Empedocles. Having then referred to Plato, he quoted the last words of Socrates: "Crito, I owe a cock to Æsculapius," and said that their exact significance was not known.

Passing to the beginning of the Christian era, he quoted from Aristides and also from St. Cyprian, as expressing the opinions of the Fathers of the church, and showed that the same general idea concerning disease prevailed. Thus, for a thousand years, at least, it was the general belief that it was due to the anger or malice of some supernatural power, and that cures were effected by divine interference. He then went back to Aristophanes, 400 B.C., and gave a sketch of the references to resorting to the temples of Æsculapius in the "Wasps." The most detailed account of the subject in any ancient author, however, was given in his "Plutus," from which Professor Merriam quoted at length.

To pass from the Æsculapium of Athens to the Æsculapium of Epidaurus, he continued, was to go from the offspring to the parent, since the temple of the latter was the more ancient and by far the more important. It was built about the end of the fifth century B.C., and many ancient authors referred to it. The excavations at Epidaurus were commenced in 1881 by the Athenian Archaeological Society, and if, as had been stated, it was true that

the temples of Æsculapius were almost always placed in the most salubrious locations, the site of this one certainly bore out the assertion. He then gave an account of the excavations and discoveries, and spoke particularly of some slabs with inscriptions, one of which was comparatively perfect, and of a very fine kind of stone. The inscription on it, which was written in the Doric dialect, gave an account of some of the miraculous cures which were effected in those visiting the temple for relief. The first history related was that of a woman who had been "five years with child," and came as a suppliant for delivery. She had a vision from the god during the night, and the next day was safely delivered of a boy, who immediately washed himself in the fountain and began to walk about with his mother. The belief in delayed births seemed to be very common among the ancients. Another account was of "One-eyed Ambrosia from Athens," who was altogether incredulous of cures from visions, and laughed at the tablets commemorating them that were placed about the walls. Yet she slept in the temple and herself had a vision from the god, who told her that she would be cured on condition that she devoted a silver pig to him. She promised to do so, and the next morning her eye was restored. There was positive evidence that the slab on which these inscriptions were written was one of those identical tablets seen by Pausanias when he was at Epidaurus. The accounts of the different cures are simple, straightforward tales, without any attempt at rhetorical flourishes. The form of the letters in which they were written was that belonging to the third century B.C., but the histories themselves were evidently of much older date than this. The latest discoveries at Epidaurus had brought to light two slabs which were the oldest of all, belonging to the sixth century B.C.

Strabo intimated that Hippocrates obtained his knowledge of the healing art at the Æsculapian temple at Cos; but at Epidaurus no mention was made in the inscriptions of the use of any remedies; all the cures being miraculous. Later the priests probably became more or less skilled in the treatment of disease, and the most complete account of their duties and mode of life that remains was preserved in the temple at Athens. Having spoken at some length of the priests, Professor Merriam took up the subject of the attitude of the physicians of the day toward these temples of Æsculapius. When the great conflict between science and religion began in Greece in the fifth century B.C., the opinions held by the philosophers were very conflicting. Socrates taught that the spheres of the two were entirely distinct and separate; while Anaxagoras, on the other hand, explained all things on a physical basis. The general public still believed that the gods were at all times ready to interfere in a miraculous manner with human affairs. Hippocrates declared that disease was all human, and at the same time all divine. He gave a rationalistic explanation of the disease of the Scythians, saying that nature was behind this, and that nothing was done without nature. Democritus said that men were mortal gods and gods immortal men; a belief which was very deeply rooted among the Greeks.

The bitter polemic of Hippocrates, in his treatise

on epilepsy, was against the magicians, and not against the priests of the temples. Galen, who was as free from superstition as almost any writer of antiquity, spoke more than once of the divine interference of Æsculapius, and it seemed to him that this must undoubtedly refer to the cult of Æsculapius in the temple of the god. There was, therefore, no antagonism between the priests and the physicians, and he thought it quite probable that when the latter had chronic cases or others which they wanted to get rid of, they sent them to the temples for relief. Scepticism as to the efficacy of the temple treatment, however, was constantly increasing among the people at large, as it was among the medical profession. But some of the priests were themselves physicians, and that the faith in the value of the ministrations of the temples was at one time very widespread was shown by the fact that no less than 320 temples of Æsculapius were known to have existed in antiquity.

On motion of Dr. ALFRED C. POST, the thanks of the Academy were presented to Professor Merriam for his learned, interesting, and instructive lecture, and he was requested to furnish a copy for publication.

### Recent Literature.

*Denison's Seasonal Climatic Map of the United States.* By CHARLES DENISON, M.D., Denver, Colorado. Chicago: Rand, McNally & Co.

The compiler of this map is well known as the author of the "Rocky Mountain Health Resorts," and we accept his name as a guaranty of the correctness of the charts, which each represent the condensation of about 5,000,000 separate Signal Service observations. The correctness of the charts being granted, there can be only one opinion as to their usefulness, and that a favorable one, illustrating graphically as they do combined humidity statistics with isotherms, wind statistics, and seasonal tables.

There are, in all, five charts, printed on both sides of a wall-map, fifty-eight by forty-one inches. Upon one side is an annual climatic map of the United States, and upon the reverse four separate seasonal maps for spring, summer, autumn, and winter. The isotherms give the average temperatures (Fahrenheit) since the Signal Service stations were established; differently figured arrows represent in the same way the prevailing, rain-bearing, and pleasant-weather winds, and the local dryness and moisture are indicated by colors and shades of colors.

These maps cannot fail to prove interesting to all who for any reason concern themselves with climates, but for physicians they will have an especial value.

### CONTINUATION OF THE INDEX MEDICUS.

DRS. BILLINGS and FLETCHER announce that Mr. George S. Davis, of Detroit, has gallantly undertaken to continue the publication of the *Index Medicus*, on the same general plan, and with the same regard to topographical accuracy and finish, as heretofore. On account of the delay required to perfect this arrangement, the first number of the *Index* for the current year will comprise the literature of January, February, and March, after which it will appear monthly, as usual. At the end of the year, in addition to the usual annual index of names, subscribers will be furnished with an index of subjects to the volume. It is requested that all exchanges, and books and pamphlets for notice, be sent to the *Index Medicus*, Washington, D. C.

# Medical and Surgical Journal.

THURSDAY, MARCH 26, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by CUTPES, UPHAM & CO., Boston. Price, 15 cents a number: \$5.00 a year, including postage, to subscribers in the United States and Canada. Foreign subscribers are charged the postage in addition.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUTPES, UPHAM AND COMPANY,

283 WASHINGTON STREET, BOSTON, MASS.

## MORE DIPLOMAS.

AMONG the stories that are constantly reappearing in various shapes in the comic literature of the day is one of the cat that, no matter how carefully drowned, always greets its master on his return from the expedition which he supposed had already closed pussy's earthly career. The story recurs to our mind at the reappearance of the Philadelphia diploma-monger. But the various forms of the legend would seem to indicate that the famed plurality of feline life is common to the species, or at least is possessed by many individuals of the tribe, and we have recent evidence that the famous Philadelphia has no monopoly of the art of mysterious resurrections.

We have before us a printed broadside dated at the Palace Hotel, Cincinnati, Ohio, and addressed to My Dear Doctor, which sets forth that the Trustees of the Bellevue Medical College have decided to incorporate a Veterinary Department, and to fill the faculty from the list of those advanced graduates of the Ontario Veterinary College who are, or may become, members of the Alumni Society; and, further, that each member of the Veterinary Faculty will receive a yearly salary of twelve hundred dollars (\$1,200); and yet further, that such salary shall be payable monthly, beginning from the date of appointment. In addition to receiving his salary, each member of the faculty will be required to attend the college during the regular sessions. A form of application is appended for membership in the Alumni Society, wherein the applicant states that he encloses a life-membership fee of \$50, which a note explains will be returned if the application is not accepted. The names of rejected candidates will not be published, and the trustees have already carefully considered the names of all those who will receive invitations. Canadian money will be accepted.

But might not a man who should be so fortunate as to be accepted as a member of the Alumni Association, and on the other hand so unfortunate as not to be appointed a member of the faculty, at a

salary of twelve hundred dollars, payable monthly, feel that his membership in return for his fifty dollars was an insufficient *quid pro quo*? There are people who feel wronged when they find that some one else has drawn the prize in the lottery. To meet the complaints of such unreasonable people, and to create a lottery in which each man shall draw a prize, it is casually mentioned (to some minds it might possibly explain the reason for the existence of the Alumni Society) that "the College will also confer the Hon. Diploma of Doctor of Medicine (M.D.) upon all the members of the faculty and Alumni Society."

From the lower left-hand corner of this document, like the legendary cat upon the fence, the seal of the "Bellevue Medical College, chartered by the Commonwealth of Mass.," smiles upon us.

The name of the Bellevue Medical College, of Boston, is familiar to our readers. Its character was made known in a late report of the Illinois State Board of Health, and the information in regard to it was fully set forth in the editorial columns of this journal, in the number of December 7, 1882. It was supposed that the exposure of the school and the subsequent action of the Legislature, which made a special act necessary for the establishment of an institution with the power to grant degrees, had given a quietus to this concern, which has been so aptly termed a diploma mill. The seal of the concern evidently survives as well as the individuals who are willing to profit by its trade. Of the Ontario Veterinary College we have no information to impart, or rather, only the negative information that it holds no charter under the laws of Massachusetts. It must, however, be judged by the company it keeps.

This most extraordinary scheme seems to have been framed for the purpose of evading existing laws, and so dividing the responsibility between different States as to make it difficult to restrain the issuing of diplomas. Such an issue of diplomas we take to be the only object of the scheme, for it seems impossible that any one should be induced to expend fifty dollars for the possible chance of obtaining a professorship. To give such a scheme the greatest possible publicity is the proper means by which to combat it.

## THE TREATMENT OF CONSTIPATION.

CONSTIPATION has been called a disorder of civilized society, being almost unknown among savages. The lower animals seem to be mostly free from it, although it is common enough among certain domesticated animals, as cats, dogs, and birds, that are pampered and lead an indolent life. It is relatively frequent among people of indoor, sedentary habits, as contrasted with those that are constantly occupied with outdoor employments. Deficiency

of muscular exercise, severe mental application and worry, and inattention to the calls of nature are recognized factors of causation. Apart from organic obstructions mechanically giving rise to it, constipation may briefly be said to be due to want of action of the intestines, or want of secretion. The want of action may be a paralytic state in which loss of sensibility or loss of contractility may predominate. The lack of secretion may pertain to the intestinal, pancreatic, or biliary glandular functions; the bile especially, from time immemorial, having had the reputation of being an alvine stimulant.

The therapeutics of constipation should be first and chiefly hygienic. Much can often be done to overcome constipation by the selection of articles of food (vegetables, coarser grains, fruits, especially dates, prunes, figs), which contain an excess of waste material, and which irritate the intestinal fibre. Physical exercise undoubtedly promotes peristalsis; the same may be said of the external application to the body of cold water; cold lavements, and even, in some persons, drinking freely of cold water, have often the same result. Exhausted or depressed innervation, whose causal agency is well recognized, may be restored by rest, change of scene, and a suitable dietary regimen. The formation of regular habits of defæcation, at certain hours, has always a prime therapeutic importance. But, unfortunately, reliance on hygienic means alone for the cure of constipation sometimes disappoints. Every physician has his incorrigible cases: patients who are always in danger of self-poisoning from the ptomaines of intestinal sepsis; whose sluggish colons will not yield up their effete contents, except under the whip of a purgative.

On such patients everything will be tried, and everything will fail to permanently benefit them. When one laxative has been used long enough to lose its effect—the intestines ceasing to respond to its incitations—another is prescribed, which, at first more successful, will eventually cease to act, except in excessive doses. It is rare that any one evacuant will remain for years the sufficient condition to normal intestinal peristalsis, although now and then this is the case. Of all the old remedies, rhubarb will doubtless continue to hold a first place among the comparatively safe and certain anti-costive medicaments (the tincture and the infusion being the most useful preparations), while among the new, cascara sagrada seems growing in credit and favor, if we may trust its testimonials; not to refer to the large use now made of the rhamnus purshiana in this country. It is an American plant, obtained on the Pacific coast, and was first introduced into practice in 1878. It has lately been made the subject of experimentation on the Continent, and has proved to be of singular efficiency in the treatment of constipation, if we may credit the favorable report of Dr. Eymeri, of Val

de Grâce, who has recently published a pamphlet on the subject. Eymeri regards it as a cholagogue as well as an intestinal stimulant; by its resins and volatile oil, it seems to act on the entire secretory apparatus as well as on the muscular fibre. The above-mentioned writer reports numerous cases in hospital and private practice, most of them coming under his own observation, where cascara sagrada, given in the form of powder, or as fluid extract (the latter form being preferred), gave most gratifying results. He concludes that this medicine should have the preference over other cathartic medications, as being less likely to do harm if its use is long continued, as being tonic as well as aperient, as causing neither griping nor nausea and diarrhoea in its action. These conclusions are substantially the same as those formulated by Bundy, who is credited with the introduction of the cascara into this country. Making all due allowance for exaggeration, we have doubtless in the sagrada a valuable addition to the materia medica, though it does not always prove a certain remedy, any more than any other drug.

#### MEDICAL NOTES.

—The *Northwestern Lancet* speaks of a modest young practitioner who lost his first good patient through his blushing inquiry, "Madam, if it is a question that a gentleman may properly ask a lady, are the bowels regular?"

—According to the same journal a physician of St. Paul recently played a trick upon a midwife, who sent to him to borrow a pair of forceps, by giving her two left-handed blades. On returning them the next day, however, she reported that she had brought the child with them. Few men could have done more.

—According to a writer in the *American Journal of Obstetrics*, Michaelis, the Professor of Obstetrics at the University of Kiel, was a martyr to the doctrine of the infection of puerperal fever being carried from one patient to another. A near relative whom he had attended in confinement at a time while he was much occupied with autopsies on patients dead of puerperal fever, died of the disease, and the accoucheur, recognizing, in the light of the new investigations of Semmelweis, that he had himself carried her the infection, laid himself on a railroad track before a train and was crushed to death.

—The death is announced of Professor Frederick Theodore Frerichs, of Berlin. He was born at Aurich, in Hanover, March 24, 1819, and was educated at Göttingen. He occupied a chair at the University of Kiel, then at Breslau, and in 1859 was called to the University of Berlin. During the Franco-German War he was physician-in-chief of the army. In 1854 he received from the King of

Prussia the decoration of the Red Eagle and the title of Privy Counsellor.

—A Chinaman at Pueblo, Colorado, is reported to be doing a great business in the healing line. He keeps a drug-store in which six Chinese clerks are employed, and his average receipts are said to be from \$200 to \$400 per day. The usual number of wonderful cures are made, and New England, as is usual in such cases, is not behindhand in furnishing her quota of the patients. Which goes to show that eucure is not the only American game to which the untutored Oriental shows a ready power of adaptation.

#### NEW YORK.

—Charles White, proprietor of an "opium joint," in Clinton Place, has been sent to the penitentiary for three months and fined \$500. This is the highest penalty of the law, and it has never before been imposed on an opium-joint keeper.

—Dr. Nathaniel Ford, a well-known physician of Brooklyn, and the oldest member of the Kings County Medical Society, died on March 9th. He was seventy-three years of age.

#### PHILADELPHIA.

—The Woman's Medical College held its thirty-third annual commencement on the 11th instant, at which the degree of M.D. was conferred on twenty-two candidates. Dr. W. W. Keen delivered the valedictory address, the major part of which was devoted to a special plea for vivisection.

—Dr. Frank Woodbury has been elected Professor of Materia Medica and Therapeutics in the Medico-Chirurgical College of Philadelphia.

—It seems as if the County Medical Society of Philadelphia were really about to do something to aid in securing the enforcement of the provisions of the registration law. This act has been in operation for several years, and yet there are men practising medicine in this city in open defiance of the law, enjoying immunity because it did not seem to be the duty of any one in particular to actively prosecute these offenders. Some other county societies in this State have already been engaged in this line of duty, thereby setting a good example to the Philadelphia Society, which will act through the standing committee on hygiene and the relations of the profession to the public. The County Medical Society, also through this standing committee on hygiene, has inaugurated a series of public lectures upon subjects connected with hygiene. The first was delivered on the 11th instant, by Dr. E. O. Shakespeare, upon "Cholera," in which the modern teachings as to aetiology and prophylaxis were especially brought out, and their lessons for this community, in view of a threatened epidemic, were carefully inculcated.

### A NEW ILIAD.

For nearly ten years the Grecian tribes under the leadership of Agamemnon had waged a rude kind of warfare around a walled town known as Troy, seeking to capture it, but were for divers reasons unable, when a plague broke out in their camp which threatened to decimate the army. Homer says that it began with cattle and dogs, but this statement must be looked at as a poetical fiction; it was simply a form of malignant typhus. Great consternation prevailed throughout the army; in accordance with the superstitious notions of the times, it was currently reported that some god was provoked, and support was given to this view from the fact that Agamemnon had in his possession a beautiful captive, the maiden daughter of Chryses, priest of Apollo, whom he had refused to give up at the earnest solicitation of the father, though threatened, for his refusal, with the direst vengeance which the pagan deity could inflict. So loud and persistent on the part of the soldiers were the clamors, inspired by dread of the spreading pestilence and belief in the pyretogenic power of Apollo's (imaginary) poisoned arrows, that the "king of men" prudently thought it advisable to call a council of his chiefs, over which he himself, of course, presided. Agamemnon opened the meeting by a brief address, in which he stated the object for which he had called his chieftains together. It was known to all that a malignant epidemic had broken out among them. It was for the council to decide whether the pestilence was due to any natural, readily explicable cause, or to "Apollo's wrath." He awaited the voice of the meeting. Menelaus, on being called upon, said that he had no doubt that the popular impression was right, and that Apollo must be appeased by the sacrifice, by his brother, of the captive maiden. Calchas, the priest of Zeus, arose and vehemently repudiated the notion that this pestilence was "Apollo's work." "For my part," he said, "if I thought so I would shriek out in despair; I would pluck out one by one my hoary locks; I would abandon my priestly profession; I would sit in sackcloth and ashes the rest of my days." He continued by saying that he had too much respect for the pagan deities and for Apollo in particular, the god of the silver lyre, to suppose that any one or any number of them could be guilty of so atrocious a crime against the Grecian host. "No, friends, let us lay the blame where it belongs, on ourselves, and declare the deities innocent. This pestilence is the work of *bacteria*, not of Apollo. It is filth — bad water and bad drainage — that has done it all." Ulysses, on being called upon by the Chair, said that he had no doubt that the last speaker was right; he did not, however, profess to be an expert in *bacteriology*; he knew something of military matters, but very little about either medicine or hygiene. He had however observed that overcrowding and bad air and filthy surroundings always breed epidemics. He had himself lost three children when in Ithaca from diphtheria, and he always attributed this sickness to a foul cesspool, and not to "Apollo's anger." He observed finally that the man of all others whom

they should have first called upon—their doctor, Machaon—had not yet spoken. He would like to hear Machaon's opinion. The surgeon-in-chief of the army arose amid profound silence. He applauded the sentiments of all the speakers but the first; Menelaus's remarks savored of a superstition which he had hoped was wellnigh outgrown. He had no doubt that Calchas and Ulysses were right. He could but applaud the expression of righteous indignation which came from the lips of the priest, when he felt himself compelled before so august an assembly to vindicate the character of his god Apollo. Calchas had given the key to the solution of the problem: *It was that one word, bacteria.* "I am convinced," he added, "that this pestilential fever has appeared among us because the soldiers have been drinking the Scamander river water, which is polluted with their own filth. Your majesty should prohibit any further use of the river water for drinking purposes; it is rank with the sewage of our camps. Let the entire army be compelled to resort for their potable water-supply to the wells which we have dug, at such expense and loss of life, at the foot of Mount Ida. I have observed that those who have not drunk of the Scamander source of supply, and have taken ordinary precautions of neatness and cleanliness about their tents, have been spared the visitation of the epidemic."

This speech made a great sensation in the Grecian army. Machaon was given full powers to stamp out the epidemic. The camps were removed to healthier quarters, and all the paraphernalia, utensils, and clothing were thoroughly purified by burning sulphur. The Scamander was used only as a sewer, and pure drinking-water was regularly brought for the use of the soldiers from the wells of Mount Ida. Finally, under the new hygienic management, the plague was arrested; Agamemnon kept his captive mistress; the row with Achilles was averted; and unnumbered mighty chiefs were saved from Pluto's gloomy realm. A shorter and less sensational Iliad was the result.

## Correspondence.

### THE SANITARY CONDITION OF NANTUCKET.

Boston, March, 1885.

*Mr. Editor,*—My attention has recently been called to an article appearing in the supplement to the Fifth Annual Report of the State Board of Health, Lunacy, and Charity, entitled: "Certain questions relative to the sewerage and the sanitary condition of Nantucket." This article I have read with surprise and regret—surprise that the State Board could have lent the authority of its name to an article so superficial and misleading; regret that it should have become my duty to reply to it. But the article in question, although mistaken in fact and defective in logic, has been widely copied and freely quoted. It has done great wrong to the inhabitants of Nantucket; and it has prejudiced the value of statistics in general. Such being the case, I feel constrained to reply, however greatly I may privately regret the necessity which thus places me in antagonism with the State Board.

The conclusions arrived at in the article in question are that between the years 1871 and 1881 Nantucket was one of the most unhealthily, if not the most unhealthily, town in the State. These conclusions are

based upon a tour of inspection and upon vital statistics compiled from the records of the town clerk's report and the census of 1880. Of the tour of inspection little is said, the report relying chiefly upon its statistics for the conclusions reached. These statistics are as follows:—

In Nantucket the mortality rate for the eleven years mentioned is 30.34. In the State at large it is 19.06. In Nantucket the mortality rate from typhoid fever is 7.7 per 1,000; in the State at large, 6.42. In diphtheria the figures are: Nantucket, 18.77; State, 11.85. In dysentery, Nantucket, 4.01; State, 2.75. In phthisis, Nantucket, 63.59; State, 35.65.

These are the figures; terrible ones, certainly, and of great weight coming from so stately a source. No wonder the report says: "The cause of this excessive mortality . . . is not easily explained." But has the Board endeavored to explain it? Has it paused to consider whether its figures are authentic before offering them to the public? Let us see. Statistics to be of value must be accurate, but even if accurate, as the report truly remarks, they are not conclusive "when applied to small numbers of people and to short periods of time." Therefore, in dealing with Nantucket, since we are dealing with excessively small figures, 3,727 being the total population as given in the census of 1880, accuracy is of double importance, and yet it appears that the figures of the State Board are far from accurate.

In the first place, since the above-mentioned conclusions are based upon a comparison between the total population and the total number of deaths, it becomes necessary to inquire was 3,727 (the figures taken from the census of 1880) the total population of the town during the period in question? Was any consideration taken of the thousands of visitors, many of whom are invalids, who annually appear at Nantucket, during the summer months? The report does not say so; yet in the first summer I practised in Nantucket (1884) the town was crowded with summer visitors, several of whom died. Now, supposing that there were 6,000 summer visitors (the boat carried 6,327 in July and August of 1880, the first year that a record was kept); supposing that, of these 6,000, 1,000 remained on the island for an average of three months, as is probably the truth, then it is evident that the yearly population of the island should be rated at 4,000 instead of 3,727, figures which would reduce the mortality more nearly to its proper level. These figures, it will be seen, are based upon the number of passengers the boat carries during two of the summer months. As young children are not included in the boat's record, the benefit of the error is thus manifestly with the State Board.

Next, as to the number of deaths taken. The State Board has compiled its statistics upon the *number of burials at Nantucket*, instead of upon the number of deaths actually occurring there! I quote the statement of Captain Allen given in the report:—

"Those who died in other places and were taken to Nantucket for burial were included in the town clerk's report to the secretary of the Commonwealth as having died in Nantucket."

But that this does not vitiate the value of the statistics, we are gravely assured by Dr. S. W. Abbott, the health officer of the Board, who writes in the following terms:—

"Furthermore, the practice of conveying the bodies of persons from a distance to their native towns for burial cannot be regarded as the peculiar characteristic of Nantucket to the exclusion of other towns, and if it is urged in favor of a lessened mortality of the island population, the same reasoning may be applied to every other community in the State."

Dr. Abbott's error is self-evident. The practice may not be a peculiar characteristic, but the including of these imported bodies among the number of the town's dead surely must be. Furthermore, Nantucket,

in the census of 1840, had a population of 9,012; in 1880, of 3,727. This decrease of nearly two thirds of its total population was due to emigration. Does every other community in the State show a similar number of emigrants whose bodies at death are to be returned to their native town for burial? If not, the same reasoning will not apply to such other communities. One might as well argue that the death-rate of Forest Hills was excessive because of the annual interments there.

Thus, having seen that the State Board is in error, first, with respect to its estimate of the population, and, second, with regard to the annual number of deaths, the two vital factors upon which its conclusions are based, let us see if we can find any particular causes which might account for a high rate of mortality, did such a rate actually exist. Amongst such causes may be enumerated the following:—

(1) The inhabitants of Nantucket are old people; the old people of a town of 9,000, in fact. For in the exodus of 1845-55 the young people migrated while the old people remained. This is shown by the average age at death at Nantucket for seventeen years; in Nantucket it being 52.11, against 30.34 in the State. That old people must die is a phenomenon which has hitherto been recognized from the earliest times and amongst barbarous nations. In some countries, indeed, they kill the old people, a plan which might recommend itself to us in Massachusetts for dealing with our decrepit institutions!

(2) The pauper element of the former population remains. Nantucket has more paupers in its almshouse, in proportion to its population, than has any other town in the State.

(3) Deaths from causality at sea; shipwrecks on the coast of Nantucket. Deaths which are included amongst the town's dead, although they cannot be so considered. Under the application of this reasoning Gettysburg must have been an extremely unhealthy locality in the early part of July, 1863.

(4) By natural selection it is the strong and healthy who emigrate, the sickly who remain.

(5) The ill-regulated hand-feeding of infants; and

(6) Nantucket is a health resort. Invalids afflicted with chronic diseases, notably phthisis, seek Nantucket in search of health, a class of visitors who must of necessity swell the death-rate.

In answer to certain of these causes, the State Board may say that the number of imported invalids and of shipwrecked sailors is small. In reply to which objection I would urge the smallness of the annual number of deaths, *only eighty-seven in 1881*. The above considerations, therefore, seem to me more than sufficient to account for a high total death-rate, did such a rate actually exist, without appealing to the bad sanitary conditions which the Board endeavors to show. Now, let us turn to the specified diseases and see if we can find there any considerations in regard to them, too, which have been disregarded.

Typhoid fever is first considered. The figures are as follows: State 6.12, Nantucket (Board) 7.7. Captain Allen's, *after the elimination of deaths not occurring on the island*, 2.11. Both, as we have seen, are based upon an under-estimated population. But even with this correction, I believe these figures to be too large. In my own practice at Nantucket during the past four years, at the season too when typhoid fever is most prevalent, I have known of but two cases of this disease, one of which was contracted in New York and the other at a neighboring island. The question therefore naturally arises, how can we account for these nine deaths, said by Captain Allen to have occurred? I undecidately say that I do not believe these nine deaths did occur, in support of which opinion I appeal to a peculiarity of the island not previously mentioned. In Nantucket, if we include an "necr doctor and a cancer doctor," there have been,

to my knowledge, eight resident physicians practising during the eleven years mentioned, all of them being at one and the same time residents of the island. Of these seven only one was a member of the State Society. Now out of the nine deaths of typhoid fever in but three is the name of the reporting physician recorded, *and in all of these three the recording physician was an unqualified man, having neither a medical diploma nor a medical education*. How many of the remaining six deaths are recorded upon similar testimony it is impossible to say. There is nothing to prove that all were not reported by the same or similar authority.

Taking the population of Nantucket then at 4,000 instead of at 3,727, disregarding the 20 deaths which occurred off the island, and supposing that the unqualified practitioner, who reported the only 3 deaths in which the physician's name is recorded, was right in one half his diagnoses, we shall have a death-rate at Nantucket from typhoid fever of 2.10 against the 7.7 given by the Board, *a rate 4.30 more favorable than that of the State at large*. Diphtheria I have never encountered on the island. The report, however, says that there were 70 deaths, or 18.77 per 1,000, for the 11 years, and Captain Allen, after eliminating deaths from this disease not occurring on the island, has collated 49, or 10.46 per 1,000 for the same period. As previously stated, both these rates are based upon an under-estimated population. Otherwise Captain Allen's figures should be nearly correct, the only error lying in mistaken diagnosis: two of the 49 deaths only being known to be reported by qualified practitioners. This rate, however, *although 1.85 more favorable than that of the State at large*, is probably higher than it should be, not because Nantucket is unhealthy, but first, because those measures to prevent the spread of the disease customary in other communities were neglected in Nantucket during the period from which the statistics were derived, and, second, because of the before-mentioned peculiarities of the Nantucket medical practice. Tracheotomy has never been performed on the island, yet under the most favorable circumstances tracheotomy saves nearly 11 per cent.<sup>1</sup> Moreover, the epidemics said to have occurred may have been of an unusually severe character, and, as the Board asserts, in an ingeniously inserted foot-note, "epidemics are always liable to affect mortality-rates unfavorably," and, referring to the supposed epidemics which are said to have lasted for five years, "such a result might happen to any similar community."

In dysentery the figures are as follows:—Nantucket (State Board) 4.01; Captain Allen, deaths of natives dying off the island eliminated, 3.22; State at large, 2.75. According to Captain Allen there were 12 deaths in all; of these 12, 6 were in persons over 70 years of age and the remaining 6 were in children under 1 year. Thus, in the case of this disease, in addition to the under-estimation of the population, we have three sufficient means of rebuttal: first, that so-called dysentery is one of the commonest causes of death among the aged, and in Nantucket the population is largely composed of old people, the average age at death being 50 years greater than in the State at large; second, the large number of summer visitors at Nantucket during the season when so-called dysentery is most prevalent; and, third, that 50 per cent. of the deaths recorded were in infants. Who can say that of these 6 children's deaths, some were not in truth due to enterocolitis, the commonest type of enteric disease amongst the very young? Lastly we come to the consideration of phthisis, in which disease the fallacy of the Board's logic is most strikingly evident. "The mortality from phthisis at Nantucket is excessive and for the period named was 63.59 per 1,000, while that of the State was 33.65, and that of Dukes County still less (29.06)."

<sup>1</sup> Henshaw's *Charité Hosp.*, Berlin, *Ann. J. Med. Sc.*, Jan., 1885.

Here we have a method of reasoning which recommends itself to the Board, inasmuch as it arrives at false conclusions without the necessity of seeking out false data. *The State Board has compared the deaths from phthisis with the total number of deaths, instead of with the total population.* Let us expose the fallacy of such conclusions in the supposititious case of two towns each with a population of 1,000.

In A with a total of 24 deaths, 12 die of phthisis or 50 per cent. In B with a total of 48 deaths, 16 die of phthisis or 33 per cent. That is, in A, where an excess of 4 persons per 1,000 over A die of phthisis, the death-rate from this disease is 17 per cent. more favorable. The same reasoning makes New Orleans with its huge death-rate from phthisis more favorable with respect to this disease than is San Diego, the popular resort for consumptives.

Captain Allen's statistics in this disease (those dying off the island eliminated) are not mentioned in the report, though why omitted it is difficult to understand, when his other figures are included. But Captain Allen's figures are preserved and stand as 40.28 against 63.59 as given by the Board, although arrived at by the erroneous method noticed above. Nantucket has been regarded as a health resort for cases of phthisis largely in consequence of the researches of Dr. Bowditch, who has represented it as one of those towns in which consumption is rare.<sup>2</sup> Dr. Bowditch's state-

ment coincides with my own experience. I can recall but three cases of phthisis occurring amongst residents of the island, one case being that of a child with great scrofulous enlargement of the cervical glands; the second, also in a child, with lateral spinal curvature following upon caries of the vertebrae, and the third, a case of laryngeal phthisis in a young adult.

Thus, then, having considered the inaccuracies of the report, let us turn to the practical counsel given to the inhabitants of Nantucket: that they shall provide a pure water-supply and that they shall provide for the removal of their sewerage.

The first of these conditions is already fulfilled — nay, more than that, *was fulfilled when the report was written*, and the Board, in publishing this counsel, has been guilty of the greatest injustice to the inhabitants of Nantucket. Nantucket is abundantly supplied with pure water — water which has been analyzed by Prof. E. S. Wood, who pronounced it sufficiently pure for domestic use.<sup>3</sup> The second condition on the other hand, presents extraordinary difficulties — difficulties almost insurmountable because of the flatness of the island, its low level above the sea, and the poverty of its inhabitants. That some better system of sewerage should be adopted no one can be more anxious than I am. Yet I do not believe that the matter will be hastened by superficial data and careless reasoning.

HAROLD WILLIAMS, M.D.

<sup>2</sup> Med. Com. of the Mass. Med. Soc. vol. x., No. 2, 1862.

Deaths reported 2,672; under five years of age 880; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrheal diseases) 398; lung diseases 516; consumption 415; diphtheria and croup 145; scarlet fever 65; measles 38; typhoid fever 35; diarrheal diseases 27; cerebro-spinal meningitis 27; malarial fevers 18; erysipelas 17; whooping-cough 16; puerperal fever 10. From typhoid fever, Philadelphia 17, Baltimore and Lowell five each; St. Louis two, New York, Brooklyn, Providence, Charleston, New Bedford, and Gloucester one each. From diarrheal diseases, New York 10, Brooklyn eight, Boston two, St. Louis, Buffalo, District of Columbia, Providence, Lowell, Holyoke, and Chelsea one each. From cerebro-spinal meningitis, New York 10, St. Louis seven, Buffalo four, Nashville, Fall River, Somerville, Taunton, Brockton, and Waltham one each. From malarial fevers, New York six, Brooklyn four, Buffalo three, St. Louis erysipelas, New York and Brooklyn four each, Philadelphia three, Baltimore two, Providence, Worcester, Fall River, and Lynn one each. From whooping-cough, New York seven, Brooklyn three, Philadelphia and Lawrence two each, District of Columbia and New Bedford one each. From puerperal fever, New York, Brooklyn, and District of Columbia two each, Boston, Baltimore, St. Louis, and New Haven one each.

In 114 cities and towns of Massachusetts, with an estimated population of 1,458,096 (estimated population of the State 1,555,104), the total death-rate for the week was 19.48 against 17.75 and 20.76 for the two preceding weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,306,449, for the week ending February 28th the death-rate was 21.4. Deaths reported 3,660; infants under one year of age 850; acute diseases of the respiratory organs (London) 384; whooping-cough 113; measles 102; scarlet fever 44; fever 32; diphtheria 31; small-pox (London 18, Birmingham and Sunderland two each, Brighton and Liverpool one each) 24. The death-rates ranged from 13.9 in Portsmouth to 32.2 in Preston; Birmingham 19.4; Blackburn 21.3; Bradford 18.7; Hull 15.7; Leeds 19.7; Leicester 18.4; Liverpool 25.7; London 20.9; Manchester 24.6; Nottingham 23.9; Sheffield 21.8; Sun-derland 29.6. In Edinburgh 16.0; Glasgow 29.1; Dublin 30.3.

For the week ending February 28th in the Swiss towns there were 37 deaths from consumption, lung diseases 29, diarrheal diseases 14, diphtheria and croup 12, puerperal fever 5, typhoid fever 4, measles 3, whooping-cough 3, scarlet fever 1, small-pox 2. The death-rates were: at Geneva 15.2; Zurich 13.6; Basle 20.4; Berne 37.1.

The meteorological record for the week ending March 14th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

## EFFECTS OF CONSANGUINEOUS MARRIAGES UPON OFFSPRING.

255 WARREN ST., ROXBURY, BOSTON, MASS.  
March 23, 1885.

*Mr. Editor.*—Desiring to collect some recent data regarding the effects of consanguineous marriages upon offspring, I wish to ask through the columns of the JOURNAL the co-operation of the medical profession. Any physician, having personal or professional cognizance of any marriages within the sixth degree of kinship (second cousins), will confer a great favor by forwarding brief notes thereof to the above address. The following facts are desired: (1) *date of marriage* (approximate); (2) *age*, whenever there is no objection (this is merely to guard against duplication of cases); (3) degree of relationship between husband and wife; (4) nationality of each; (5) occupation of husband; (6) number of children born; (7) number living at present; (8) number of children healthy; (9) diseases or defects of children not healthy; (10) any other facts of interest in the case.

It is particularly wished that no selection of cases be made, but that all consanguineous marriages (including the not made especially conspicuous by reason of unfortunate results in the offspring) be impartially recorded.

Very truly yours,

C. F. WASHINGTON, M.D.

## OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE WEEK ENDED MARCH 14, 1885.

BALTIMORE, P. H., surgeon. Detailed as President, Board of Examiners. March 10, 1885.

PRINCETON, GEORGE, surgeon. Detailed as member, Board of Examiners. March 10, 1885.

AUSTIN, H. W., surgeon. Detailed as Recorder, Board of Examiners. March 10, 1885.

## THE CARTWRIGHT PRIZE.

ESSAYS in competition for the CARTWRIGHT PRIZE must be handed in to some member of the committee on or before April 1, 1885. The committee consists of Robert Abbe, M.D., 32 East 20th Street; Walter Mendelson, M.D., 290 West 46th Street; and R. W. Amidon, M.D., Chairman, 18 West 21st Street, New York.

## CORRECTION.

In the case reported by Dr. Lyman, in the Improvement report of last week, page 274, seventh line, first word, read "right" for "left."

E. M. BUCKINGHAM, Secretary.

TEN CASES OF REMOVAL OF UTERINE TUMORS BY LAPAROTOMY.<sup>1</sup>

BY JOHN HOMANS, M.D.,

*Surgeon to the Massachusetts General Hospital, and Instructor in Harvard University on the Diagnosis and Treatment of Ovarian Tumors.*

PROBABLY hysterectomy will never be so successful as ovariectomy has become in practised hands, but its mortality will undoubtedly be much diminished when it is done before the tumor has grown enormously large, and the vital functions have almost ceased, and the patient has become helpless and feeble. The difficulty about knowing when to operate is one of prognosis. If we only knew what tumors, or class of tumors, were destined to grow and become so large as to cause death by mechanical pressure, and what ones, on the other hand, would become smaller, or even atrophy and disappear entirely, then we could pick out proper cases for early operation. I have seen cases where delay and the use of ergot have been advised where the advice has been followed by diminution in the size of the tumor, and other cases where similar advice has been followed by its growth to an unbearable or even enormous size. I am quite sceptical as to the value of ergot in most of these cases where the growths are subperitoneal or interstitial and lie nearer the outer surface than the cavity of the uterus. In regard to prognosis, if I should hazard an opinion, which I may very possibly have to retract, I should say that the fibro-myomatous tumors which lie beneath the peritoneal covering of the uterus were more likely to become harmful and fatal by increase of size than those that lie more deeply in the substance of the organ. These exterior tumors probably get a greater blood-supply and are more vascular than those that are more intra-mural. This increased vascularity comes from their proximity to the peritoneum of the uterus, of the omentum, and of the mesentery, and I think that these tumors more frequently require hysterectomy than the deeper ones. In the English and American journals about five hundred cases of hysterectomy have been reported, and in the Continental and other journals many more. A very few operators have excellent results and others bad or indifferent. Some treat the stump (that is, that portion of the uterus which is left behind, or in exceptional cases the vaginal wall) intra- and others extra-peritoneally; that is to say, that some drop it back and sew up the abdominal wound, and others hold it up outside the skin and sew up the wound around it, keeping the end of the stump above the surface by means of one or more long pins passed through and having their ends resting on the skin of the abdomen. I have had success both ways, and failures also. If the stump is a moderate-sized one I am rather inclined to treat it intra-peritoneally after searing it brown with the cautery, so that it would be nearly as dry and tough as sole-leather.

As I said above, if we could tell what tumors would grow, we should know when to operate early, and not find that a woman, whom, two or three years

before, we had told to dismiss her condition from her mind, and that her bunches would never grow, nor ever trouble her, had become a confirmed, worn-out invalid, with a solid growth reaching to the ensiform cartilage, and almost irremovable, whereas, if an operation had been done when she was first seen and in robust health she would more probably have been cured. Since many, but not all, fibroids cease to grow coincidentally with the menopause, it has been proposed that an artificial menopause should be brought about by removal of the ovaries, and this seems certainly a surgical proceeding based on as sound physiological reasoning as one can imagine or wish for. Reported successes have followed this mode of treatment and reported failures, but I think the former outnumber the latter. I have only removed the uterine appendages twice for the cure of uterine myomata.

Again, in regard to the ages of the patients, Dr. Keith thinks that hysterectomy would be proper in cases of rapidly growing or largely hemorrhagic tumors in young persons, or in persons under thirty years of age, but I have seen the most rapid growths in patients between forty-five and fifty-five years old when the catamenia seemed to have ceased or appeared only once in six months. One of the most, perhaps the most, useful book to study on ovariectomy is the first book published by Sir Spencer Wells, in 1865. It is entitled "Diseases of the ovaries," and gives an account (in minute detail) of one hundred and fourteen cases of ovariectomy; each case has its previous history, given at great length, the reasons for operating are stated, the operation is described fully, and each day's progress is often minutely recorded. Here one can see the successes and failures, the efforts to make success more certain and to avoid errors. Only one volume was published. If Sir Spencer had continued to describe all his cases afterward in this form we should have had a very large array of facts and observations, among which we could have found a parallel for every complication that could possibly arise. I wish we had such a volume on hysterectomies. In the following small number of cases of partial or complete hysterectomy will be found four recoveries and six deaths. Of the four women who recovered, three were in good health and one was somewhat exhausted; of the six who died one was in robust health, and the others were more or less exhausted, two being bedridden and having bed-sores at the time of the operation.

In three of the fatal cases the pedicles of the tumors were such as to have been easily managed if removal had been attempted early. All these cases were treated antiseptically and with the spray. None of these operations were undertaken except to save life or relieve intense physical pain.

CASE I. — April 5, 1881, Carney Hospital. A fibro-cystic tumor weighing two pounds was removed from the fundus of the uterus during an ovariectomy; its base was transfixed, cauterized, and tied, as I usually do, with the ovarian pedicle. Recovery was uninterrupted. Dr. W. W. Gannett reported the tumor to be a fibro-myoma.

CASE II. — April 11, 1883, Carney Hospital. About two thirds of a two-horned uterus, containing many pounds of bloody fluid, was removed on account

<sup>1</sup>Read before the Obstetrical Section of the Suffolk District Medical Society, February 18, 1883.

of unbearable pain. The operation is identical with hysterectomy for a fibro-myoma. As this case has been described at great length in a former number of the *JOURNAL*<sup>2</sup> and in the *London Lancet*, I will only say that the pedicle was treated extra-peritoneally in one of Sir Spencer Wells's clamps and that the patient recovered rapidly. She wrote to me on February 13, 1885, that she was perfectly well. She has not menstruated since the operation.

CASE III. — April 24, 1883, St. Margaret's Home. Patient forty-three years old, married, six children; she had known of the existence of the tumor for four years, and had been an invalid for eight years. Two months before she came to St. Margaret's she had been tapped on account of distress and discomfort, and sixteen pounds of ascitic fluid had been drawn off. The breathing was labored and the urine much diminished; there was a bed sore over the sacrum. The probable duration of life, if neither tapping nor hysterectomy was done, seemed but a few weeks. The abdominal girth was forty-one inches. An incision, seven inches long, was made from above the umbilicus to the pubes; much ascitic fluid ran out. Adhesions to the bowel and peritoneum were tied and divided. The hemorrhage was rather free from the torn adhesions, and from the ovarian artery in the right broad ligament. A cord of rubber tubing was first tied around the base of the tumor, and, finally, a clamp, sliding on parallel bars, was fastened around the pedicle. Both ovaries were tied but the right alone was removed. The operation was an embarrassing one, owing to the perietal and intestinal adhesions which were difficult to separate. When the patient came to St. Margaret's Home she had a bed sore, and this, and the constitutional condition which a bed sore usually implies, contributed much to the ultimately fatal result of the operation. Her condition was not at all discouraging until the fifth day, although the bed sore was a continual annoyance. At this time the abdomen became somewhat distended. The clamp, which had sunk almost out of sight, now came away. There was more or less discharge which was thoroughly removed by gentle syringing. The temperature rose on the second day to the evening to 102.2° F., and then fell to 100.5°, where it remained till the eighth day, when it rose to 101.5°. The bed sore kept increasing and on the twelfth day she had a chill and died on the fourteenth day. As there was no autopsy, I cannot say what the exact cause of death was, but I suppose septicæmia, but whether from the bed sore or the hysterectomy, or both combined, I cannot say. With my added experience since I feel as if, possibly, the issue might be different to-day if I had it to do over again. At any rate, it was a proper attempt to save life and restore the woman to health.

CASE IV. — October 9, 1883, St. Margaret's Home; patient a single woman, thirty-five years old. Tumor discovered two years before operation; it had caused very severe pain and menorrhagia. I consented to operate on account of the excruciating pain. The tumor weighed eight pounds and was attached to the uterus by a pedicle about two inches in diameter and was, I think, treated intra-peritoneally.

The patient died on the fourth day, I presume of peritonitis.

CASE V. — November 3, 1883, St. Margaret's Home; patient forty-four years old, married. The menopause had occurred a year before, but the tumor had continued to grow rapidly; indeed it had only been discovered a year before the operation. There were ascites and general anasarca. Patient could not lie down and was beginning to have a bed sore. On opening the abdomen a solid red fleshy-looking tumor presented itself. It was adherent to the anterior parietes and to the transverse colon. There was more or less venous hæmorrhage when these adhesions were separated; the incision was several times enlarged until it measured thirteen and a half inches. The upper part of the tumor which had pressed the diaphragm into the chest was pulled out and various adhesions were clamped. A pedicle was found coming from the right horn of the uterus and was treated by ligature and cauterization and dropped back. All bleeding points were carefully tied and the abdomen carefully cleaned. The tumor weighed forty-five pounds, and measured forty-five and a half inches in its longest circumference and thirty-four and a half in its shortest. Its diameters were thirteen and ten inches respectively. The patient died of shock twenty-four hours after the operation. This was an attempt to save life in a woman exhausted by the mechanical pressure and weight of the tumor. Without operation she might have lived days or perhaps weeks, but not long.

CASE VI. — June 12, 1884, St. Margaret's Home; married, thirty-six years old. Hæmorrhage from uterus almost constant and at times violent; severe unbearable pain. The tumor was found to be covered by the left broad ligament under which it glided when moved. I began to cut through the layers of the broad ligament and to enucleate the tumor, but this I abandoned. At the upper border of the tumor the intestines were adherent and I divided the serous covering of the tumor and clamped the cut edges. The wire of a Kæberle's serre-neud was passed around the tumor and pushed as far down in the pelvis as possible. The loop included the right ovary and tube but not the left, which latter I did not feel. The wire was tightened and drawn through the canula and screwed up, then another serre-neud (it is always well to have two) was passed round the pedicle and screwed up, after which the first one was removed. Pins were passed through the pedicle just above the wire, the wound closed, the stump secured outside the skin and painted with persulphate of iron. The portion of tumor removed was solid and weighed two and a quarter pounds, and contained half an inch of the cavity of the uterus. As much or more of the tumor was left behind. The after progress of the case was satisfactory. On June 20 the stitches were taken out and then began the very remarkable progress of this case. In a few days the remainder of the tumor began to be extruded through the stump and in ten days it had risen to a height of two inches above the skin. Severe pain now occurred at intervals. Rubber bands were put around the base of the tumor and kept on as long as their pressure could be borne; all this

<sup>2</sup> November 9, 1881. *London Lancet*, November, 1883.

time the tumor was not only being extruded from the abdomen but was growing perceptibly to the eye. On the nineteenth of July a silk ligature was tightly tied around the base of the tumor and the superjacent portion cut off. It weighed four pounds. This manipulation caused considerable constitutional disturbance and sent the temperature to 104°, but this subsided in twenty-four hours to 98.2°. On August 2d she went home. In November an abscess opened and discharged freely though the wound. She is now, February, 1885, well, hearty, strong, fat, working hard, and entirely free from pain. She menstruates every three weeks. Dr. E. G. Cutler described the tumor as a fibromyoma with cystic and mucoid degeneration. This is, so far as I know, a unique case.

CASE VII.—August 6, 1881. St. Margaret's Home. Patient single, twenty-six years old, healthy. Tumor growing rapidly. The tumor was not adherent. Koberle's serre-noud was secured around the body of the uterus on a level with the origin of the Fallopian tubes. The right ovary and tube were removed. The stump was secured outside and treated as in the former case. The tumor was a dense fibroid, ovoid in shape, and weighed seven and a half pounds. It was found that two and a half inches of the uterine cavity was removed with the tumor. In external appearance the tumor closely resembled the dura mater covering the brain, as it is seen when the calvaria is removed. The patient and her attendants made a good fight, but death occurred on the ninth day, I suppose from some form of septicaemia. At the autopsy the stomach was seen *wholly* filling the anterior abdominal cavity and being about sixteen inches in diameter. It contained much gas and seven pounds of black fluid. The intestines were not distended but seemed flat and narrow just above the ileo-caecal valve. No lymph, pus, nor fluid was in the peritoneal cavity; the wound had united and the intestines were glued to it. I suppose death occurred from septicaemia, but paralysis of the stomach and intestines had, I think, something to do with it.

CASE VIII.—St. Margaret's Home, December 6, 1884. A single woman, twenty-six years old. The urine was diminished in amount and contained a well-marked trace of albumen; at times she had required the use of the catheter. The tumor was first noticed eight months before and had grown rapidly during the past few months. On opening the abdomen the omentum was found to be adherent to the pubes and was tied above and below. A cork-screw was put into the tumor and its entrance was followed by a gush of clear yellow fluid from a cyst. The tumor was lifted out by this handle (a proceeding I learned from Mr. Tait) and Dawson's clamp was easily passed around its base. The clamp encircled the left half of the body of the uterus. The growth was cut through with Paquelin's cautery (the platinum flaming) and the stump was secured exactly as I do in a case of ovariotomy and dropped back. There was no bleeding. The weight of the tumor was three and a half pounds, and included the left ovary and left Fallopian tube. On its surface were eight or ten little tumors, containing fluid and varying in size from a pea to a

horse-chestnut. The tumors were fibro-myomas, with cystic degeneration. The after progress was very satisfactory, except in regard to the rate and quality of the pulse, which varied between 110 and 140 for ten days and was extremely feeble and not at all consistent with the patient's muscular and vocal strength and comfortable condition. The urine at first contained more albumen than before the operation (less than one eighth per cent.). She went home on the first of January, 1885, and has since been in excellent health.

CASE IX.—February 5, 1885. East Montpelier, Vermont. Patient thirty-four years old, married. The tumor was first noticed in 1881. It was then the size of a lemon and in the left iliac fossa; it grew slowly until the spring of 1883, and since that time has grown faster, but especially fast during the last month (January, 1885). She was very irregular in her menstruation until marriage (about a year ago) and after her marriage was regular till October, 1884. Since that time she has suffered much from nausea and greatly from abdominal pain, and was supposed to be pregnant at the time of the operation. The tumor had grown very rapidly recently. In the tumor was a lymph-space (or cyst) containing eight pounds of clear fluid and the solid portion of the tumor weighed five pounds, making the total weight thirteen pounds. She could not be moved from her bed in a farmhouse in Vermont and I went to her home and operated. The reason for operating was the unbearable pain and soreness and constitutional irritation. This latter condition was probably partially occasioned by the presence of a decomposing fetus in the uterine cavity. Both ovaries and tubes were removed and Koberle's serre-noud was tightened around the base of the tumor, above the body of the uterus, in which it was supposed a fetus might be. The case progressed favorably for two days and terminated fatally by hemorrhage on the fourth. The wire had cut through the right side of the uterus, before sufficient coagula had formed to stop bleeding. The bones of a macerated fetus were found in the uterine cavity, which I had not opened at the time of the operation.

An autopsy was made by Drs. Chandler and Lazelle. The wound had united and the uterus was well held up (although the pin and wire had come away on the third day after the operation). There was slight peritonitis and an opening into the cavity of the uterus in which lay the separated bones of a fetus and about three pints of blood. I will add the concluding words of Dr. Chandler's account of the case: "Operation Thursday noon, February 5th. Friday morning very comfortable and moved in bed, she said, with less pain than before the operation. Friday night taken with pain in right side probably from peritonitis caused by slight bleeding from the lower and right side of the stump from the giving way of the tissue under the wire. Blood was found on Saturday on the dressing and the patient was not as well. At 5 p.m. the pin and wire came away and she died Sunday at 11 a.m. from hemorrhage. The leak had probably let the fluid out of the womb, but the bones seemed to lie against the inside of the abdominal walls, without their usual coverings, all separated from

each other so that each one could be picked up without any of the others."

CASE X. — February 14, 1885. St. Margaret's Home; patient fifty years old. The presence of an abdominal tumor had been known for six years. A distinguished London ovariologist had examined the patient in 1882, and had told her that there were two bunches which would probably never trouble her and to dismiss the fact of their presence from her mind. This illustrates what I said in the early part of this paper that if we could only foresee what kind of tumors would be likely to grow, we could operate before they had attained the size of the present one and when a much shorter opening in the abdominal walls would be necessary. The incision was thirteen inches long, which contracted when sewn up to eleven. Tumor of a purple color, very dark in the neighborhood of the uterus where the right Fallopian tube and the neighboring parts stood up straight and stiff and turgid with blood like the comb of a cock. Quite a vascular adhesion to the omentum was clamped and tied. The tumor was about fifteen to eighteen inches long and twelve wide. It was raised and found not to be adherent except in the pelvis. The wire of a *serre-nœud* was passed around it and tightened, about two thirds of the tumor was then cut away (a solid fibromyoma). By further manipulation the remainder of the tumor was torn out of (enucleated) the left broad ligament which was clamped wherever a bleeding point was seen. The wire of another *serre-nœud* was passed around the uterus and right broad ligament and tightened. The left broad ligament was then tied *en masse* and separately wherever a bleeding point was seen. Some very large vessels (as will be seen in the description of the tumor) were tied; one of them was as large as the tip of the little finger. The neck of the uterus was then embraced in Dawson's clamp, tied and burnt off an inch and a half within the vaginal junction. I was careful to sear the stump thoroughly brown. The abdominal cavity had been but slightly soiled with blood, but it was carefully sponged out, and the incision closed and dressed antiseptically. The following is Dr. E. G. Cutler's description of the tumor:

"The tumor weighed thirty pounds. The shape was generally globular, here and there embossed with nodules the size of the fist and smaller. Large bloodvessels were seen ramifying on the surface. There were numerous slight adhesions to the surrounding viscera on the surface toward the pelvis; toward the abdomen an old large adhesion to the omentum had been tied. On fresh section the color of the tumor was mother-of-pearl and the consistency dense and elastic to the touch; one portion was softer and darker colored than the rest and there were dark thrombi in the vessels with staining of the surrounding tissue. This dark portion was as large as the closed hand and was evidently undergoing a degenerative change. A close inspection of the surface showed the tumor to be made up of bundles of fibres running in various directions, and some large vessels on the surface to be about a quarter of an inch in diameter. The whole tumor was unusually vascular for a fibromyoma. The uterus measured six centimeters from the fundus to the os internum, seven centimeters

from the origin of one Fallopian tube to the other, and its posterior wall was one and a half centimeters thick. The internal os and cervical canal were occluded and impervious by some old process. The mucous membrane of the uterine cavity was slightly thickened, reddened, and the two surfaces were adherent to each other, except in the centre, where a small red clot was found.

"The uterus had been removed just inside the os externum apparently. The right ovary and broad ligament were removed entire.

"The origin of the tumor was the posterior left lateral surface of the uterus near the junction of body and cervix. The length of the raw surface where the tumor had been removed was nine centimeters and its breadth five centimeters.

"Microscopic examination showed the tumor to be a fibro-myoma."

At the close of the operation the patient's pulse was eighty-eight per minute and strong, and her condition seemed quite encouraging. The second day was a very comfortable one, and there was no nausea nor vomiting. The second night was very comfortable and was passed in sleep, only one opiate of thirty drops of laudanum by rectum being required. The evening temperature was 98.9° and the pulse 102. On the third day she had vomited but once. On the fourth day the vomiting of black fluid began and continued at intervals. The evening temperature was 100.2°, and the pulse 118. A fifth of a grain of morphia subcutaneously gave her a very comfortable night, with continuous sleep. Occasionally she vomited on the fifth day, but her evening temperature was 98.4°, and this was encouraging. The pulse was 126 and the respiration 17. The pulse grew weaker through the night, and death took place on the sixth day; that is, five days after the operation of removing the tumor. An autopsy showed the cause of death to have been a moderate amount of peritonitis, caused partly by the sloughing end of the tied omentum and partly by the manipulation during the operation. The ureters were both found dilated, probably from the obstruction caused by the heavy tumor resting upon them. The right ureter was the larger and with the enlarged pelvis and calices of the kidney formed a cyst the size of the fist. The cortical substance of the kidney was thinned but seemed healthy.

This ends the record of my hysterectomies up to the present time. The percentage of recoveries is not as large as I wish it was. Of those who died, three were exhausted by the disease and two were bedridden and had bedsores. The four who recovered were rescued from a life of suffering and a lingering death. So far as these cases go, partial removal of the uterus by laparotomy seems as successful as total. In Case IX., Porro's operation would have been the proper one *if we had known before the operation all we know now*. It is easy to reason after the event. Case II., in which the remainder of the tumor was extruded through the abdominal parietes after the clamp had come off, and also grew visibly during this process, is perfectly unique, so far as I know. The result of the process was a perfect cure. The top of the uterus perfectly flat and covered with healthy cicatricial

skin fills the site of the abdominal wound. In regard to the treatment of the pedicle, I hope that in most cases some intra-peritoneal method may be found, perhaps by burning with the cautery. No rule can be made at present, however, and each case must be treated independently.

### SOME CLINICAL OBSERVATIONS IN REGARD TO MONO-CHOREAS ASSOCIATED WITH INCREASED TEMPERATURE OF THE PART AFFECTED.

BY HOBART AMORY HARE, M.D. (UNIV. OF PA.).

*Attending Physician to the Children's Dispensary of the University Hospital of Philadelphia.*

The following cases are reported in order to call attention to what seems to be quite a common occurrence in mono-choreas, namely, an increase in the temperature of the member or part affected. So far as I know, such changes in temperature in this disease have not been reported; although, as every one knows, it is quite common in hemi-choreas to have a decrease in temperature of the side affected, accompanied generally by profuse perspiration. In the cases here reported the member affected was invariably hot, dry, and feverish. The color of the skin was more red than normal, the skin also had rather an injected appearance.

The coldness of the parts in hemi-chorea is probably due to some neurosis affecting the blood-supply and also to the constant evaporation of the perspiration, which is caused probably by some disorder connected intimately with the nerves governing the sweat-glands. It is entirely permissible to account for the increase of temperature noted in these cases by supposing that the neurosis may be such as to cause the contrary effect of that mentioned in regard to the coldness of the parts, namely, an increased supply of the arterial blood instead of a decreased supply. There is a possibility that this increase of temperature may be due to the constant muscular movements peculiar to the disease, but this is very improbable, since the heat developed by the movements in so few muscles would not be appreciable. It seems to me that the redness and injection of the skin point to the conclusion that the difference in temperature between the affected and unaffected members is due to the inordinate supply of arterial blood in the part. In one or two cases it was impossible to find the temperature of the part by the thermometer, since the hand was often hot and feverish and the axilla normal. As the thermometer used was the one commonly in use at the bedside, it was impossible to take the temperature of the palmar surfaces.

CASE I. Katy Burns, aged eight, came to the Dispensary of the Children's Hospital<sup>1</sup> of this city, suffering from a mono-chorea of the left arm. The child appeared strong and in good health, although the face was perhaps lacking in color. The mother stated that about one week previously she had noticed this peculiar and constant twitching of the arm, which kept up night and day, and had first

ascribed it to "nidgetyness" but had found that it could not be controlled by the will. The child has never had scarlet fever, diphtheria, or rheumatism. She had measles some years ago, but made a good and rapid recovery. On examining the hand and arm they were found redder than normal and the skin was dry, hot, and feverish. The temperature of the right axilla was 98.4°, while that of the left axilla was 99.8°, an increase of 1.4° over the normal side. The heat was normal, the appetite good, and the bowels regular. This case recovered entirely in the course of four weeks, receiving three drops of Fowler's solution three times a day during that space of time. There is no difference between the two axillae at this writing and the reddened appearance of the skin has disappeared, the two arms and hands having the same hue.

CASE II. Peter F., aged twelve, came to the Children's Dispensary of the University Hospital last fall, suffering with left brachial mono-chorea of a moderate type. Had a history of scarlet fever just preceding the choreic attack, which came on during convalescence; at least it was first noticed about this time by the parents. His heart was normal and his appetite generally quite good. His bowels were regular. There is a history of rheumatism in the family, although the boy seems never to have been a sufferer from it in any degree whatsoever. His condition was fair and there was very little, if any, anemia present. At that time he was put on Fowler's solution, and is still taking it, as he has not entirely recovered the control of his arm when certain movements are desired. As there seemed to be some slight loss of power he was given in addition to the Fowler a small amount of strychnia, about the fortieth of a grain, four times a day. When first examined there was a great deal of difference in temperature between the two arms and hands, the left hand feeling hot to the touch while the right was normal. The temperature in the axillae was 99° and 98.1° respectively. The difference between the axillae to the touch was scarcely noticeable, while, as already stated, the difference of temperature to the touch at the hands was marked. At present there is not much difference between the two members and the movements are not as severe as formerly, although it is doubtful whether they will ever cease entirely under his present mode of living and owing to the obstinacy of the disease in resisting treatment for so long time. The fact that the chorea followed scarlet fever would also point to an unfavorable prognosis. I forgot to mention that the affected arm in this case was also redder than normal.

CASE III. Lizzie D., aged ten, two years ago had an attack of scarlet fever from which she entirely recovered. During the stage of desquamation, however, the mother noticed that her right arm was beginning to twitch, and by the time she was up and about, the choreic movements had become quite severe. During the last two years the movements have been constant, being somewhat less severe at night than during the day, and varying in intensity at different seasons, as in the spring for example. There is no history of paralysis following the attack of scarlet fever nor is there any history of rheumatism. The heart sounds are

<sup>1</sup> I am able to mention this case through the kindness of Dr. Louis Starr, the physician in charge of the Dispensary at the time the patient presented herself.

normal, the appetite is good, and the bowels slightly constipated. The movements are increased if spoken of in her presence. The possibility of any reflex irritation owing to intestinal worms was dispelled by the administration of male fern, chenopodium, and injections of turpentine and sweet oil. There is no history of masturbation or other genital irritation of any kind. No history of fright or chorea prior to the scarlatinous attack. No anemia. The girl would generally be considered strong and sturdy and does not appear to be of a markedly nervous temperament. The hand and arm affected (the right) were warmer than the left. This difference was only appreciable by the touch, since the thermometer in the axillæ marked the same number of degrees in both cases. The right hand was hot, dry, and feverish, although the weather was cold and the child had come some distance. This case also recovered under the use of arsenic, the red hue of the hand and arm gradually disappearing as the patient's condition improved.

CASE IV. George N., aged thirteen, came to the Dispensary of the University Hospital suffering from an irregular form of chorea, which, at times, affects the whole body, but which is constantly present to a slight degree in the right arm, from which point the movements extend when he is suddenly frightened or greatly excited, as by the sight of a runaway horse or something of a similar character. The arm does not appear to be much warmer than normal unless the movements are about to extend to the rest of the body, when the boy will say to his parents, "It's coming, my hand is getting hot," and within the next few minutes the general attack comes on.<sup>2</sup> That this attack is not epileptic is shown by the fact that there is never loss of consciousness or frothing at the mouth. He keeps on saying what he wishes to say as if nothing was occurring, although his mother tells me that his words are not articulated clearly, owing to the movements affecting the muscles of his mouth. He never falls down during an attack and goes on with his work (sewing rag carpet) after the attack passes off as if nothing had occurred, although he is entirely conscious of his having had one. If asked a question during an attack he will invariably give a clear and lucid answer. The beginning of this trouble dates back six years. At that time, while at Atlantic City, he was forced by his parents to take a surf-bath although he was much averse to it, owing to fright. He no sooner reached the water than his kicking and screaming was replaced by rigidity. This alarmed the parents, and they immediately took him out and dressed him. After a few hours the child seemed perfectly well. In the course of the next few weeks the mother noticed a slight twitching of the eyelids, chiefly affecting the left side. This was so slight that the father denied its presence. This, however, passed away at the approach of winter. The following spring the movements appeared in the right arm, and from this point have annually made further inroads on the rest of the system till the present condition has been reached. During the summer, when he is out of town, he becomes almost

entirely well. Sometimes the attacks come on without apparent cause, generally in such cases following several days of unusual quietude. One of the frequent causes of a general attack is an imperative call, on the part of his father, to get up in the morning. The boy has improved slightly under the use of arsenic and tonics. He, however, is in every way, but that mentioned, healthy, strong, well-grown, and the possessor of a good digestion and appetite.

This case, although not that of an ordinary chorea, is very interesting, as showing the change of temperature which takes place just before and during the movements of the arm, which seems to be the focus of each attack.

CASE V. Robert P., aged nine. Came to the Dispensary suffering from a constant and incessant chronic movement of the eyelids.<sup>3</sup> To all appearance he is a strong, healthy boy and not of a neurotic temperament. He is only a little pale and would not be regarded as anemic. His mother states that last fall he had an attack of scarlet fever and this trouble came on during convalescence. The closest questioning fails to elicit any history of paralysis, or of this disease in any form prior to the attack of scarlet fever just mentioned. There are no abnormalities about the heart and there is no history of rheumatism. The appetite is good and so is digestion. The bowels are in good order. The eyelids, particularly the upper lids, are infected, redder than normal, hot and feverish to the touch. The boy also states that his "eyes feel hot," referring to the lids. There is no change in the eyes themselves, either in the manner of moving the ball or change of the pupil. Unfortunately the actual temperature could not be taken owing to the exposed position of the parts.

The treatment of this case consisted in the administration of Fowler's solution, the child recovering in about three weeks.

### SUFFOLK DISTRICT MEDICAL SOCIETY.

#### SECTION OF OBSTETRICS AND GYNECOLOGY.

ROBERT B. DIXON, M.D., SECRETARY.

FEBRUARY 18, 1885. DR. JAMES R. CHADWICK in the chair.

DR. JOHN HOMANS read a paper entitled

#### TEN CASES OF REMOVAL OF UTERINE TUMORS BY LAPAROTOMY.

Dr. J. W. ELLIOT remarked that the reader was especially to be congratulated on his success in the last case mentioned. For other operators had found the mortality very high in this class of cases, that is, cases where the tumor grows more or less from the cervix and extends into the broad ligament.

Dr. Homans's conclusions in regard to the intra-peritoneal treatment of the stump were of interest because they were opposed to the conclusions one would draw from the statistics of other operators. In ovariotomy the pedicle was at first treated by

<sup>2</sup>The mother says that the hand felt hot to the touch and that the boy knew the approach of the attack, but by any change of feeling in the affected arm, but by the feeling which is conveyed to the normal hand of increased heat when the affected hand is grasped.

<sup>3</sup>This case is hardly one of mono-chorea, and is mentioned here merely because the movements were localized and accompanied by increase of temperature.

the extra-peritoneal method; this soon proved to be far inferior to the intra-peritoneal. One would naturally hope that the same advance could be made in the operation for fibroids. So far, at least, this hope has not been realized. Schroeder, of Berlin, has just completed his first 100 operations, with 32 deaths. He has had the largest experience in the intra-peritoneal method, and has much improved the operation by using the temporary elastic ligature, and by covering the stump with peritonæum. Yet his mortality is still very high. Martin, of Berlin, follows Schroeder's method, and reports 60 cases, with 20 deaths. He has tried to reduce the mortality by drainage through the vagina. Spencer Wells also uses the intra-peritoneal method, and has a mortality of forty to fifty per cent. The extra-peritoneal method has been practised more successfully by Hegar, who reports, in 1881, 12 cases with only one death; Keith, who reports, in 1883, 25 cases with two deaths; and Bantock, who reports, in 1883, 22 cases with two deaths. Thus, we see from these statistics that the intra-peritoneal method has a mortality of about thirty-three per cent. in the hands of the best operators, while the extra-peritoneal has a mortality of only eight to ten per cent.

If Dr. Homans can succeed in getting satisfactory results by the intra-peritoneal method it will be a great advance, for the advantages of this method in saving annoyance to the patient and trouble to the doctor are obvious.

The indications for the operation are as yet quite unsettled, and will, of course, depend largely on the mortality. It is an interesting fact that as this operation has been improved many fibroids which used to be removed per vaginam, with a very high rate of mortality, are now more safely removed by laparotomy. Koerberle, at the last International Medical Congress, said that only polypoid growths and fibroids that protruded into the vagina should be removed per vaginam, the rest by laparotomy.

Dr. Elliot thought that the cases best suited to removal of the uterine appendages were those of small fibroids. In such cases the weight of the tumor was unimportant, and the hemorrhage and its growth could usually be stopped by this operation.
